v. 38

Digitized by the Internet Archive
in 2015

A Weekly Journal for Amateurs and Gardeners.

FOUNDED BY W. ROBINSON,

*Author of "The English Flower Garden," "The Wild Garden," "Hardy Flowers," "Alpine Flowers," &c.
Founder of "The Garden" and "Farm and Home."*

"YOU SEE, SWEET MAID, WE MARRY
A GENTLE SCION TO THE WILDEST STOOK;
AND MAKE CONCEIVE A BARK OF BASER KIND
BY BLOOD OF NOBLER RACE: THIS IS AN ART
WHICH DOES MEND NATURE—CHANGE IT RATHER: BUT
THE ART ITSELF IS NATURE."—*Shakespeare.*

"CALL THE VALES AND BID THEM HITHER CAST
THEIR BELLS AND FLOWERETS OF A THOUSAND HUES."—*Milton.*

VOL. XXXVIII., DECEMBER 30, 1916.

LONDON:
OFFICE—63, LINCOLN'S INN FIELDS, W.C.

INDEX TO VOL. XXXVIII.

Comprising Numbers from January 1st, 1916, to December 30th, 1916.

ILLUSTRATIONS IN ITALICS.

A

ABELIA chinensis, 93, 347
 floribunda, 306, 347, 395; *f. in the greenhouse at Nymans*, 347
 grandiflora, 514
 serrata, 347
 spathulata, 347
 triflora, 347

 Abutilon Triumph, 71
vitifolium, 239, 258; *v. in Scotland*, 360
 Abutilons, 160, 624
 seedling, treatment of, 205
 stunted, 212
 Acacia Baileiana, 269
 dealbata failing, 229
 lophantha, 425
 Riceana, 99
 Acacias, greenhouse, 194
Acanthus at Myddleton House, 655
 Caroli Alexandri, 655
 culture, 655
 longifolius, 655
 mollis, 655
 Perringi, 655
 spinosus and *A. spinosissimus*, 655
 Acetylene gas refuse, 130
 Achillea ptarmica The Pearl, 306; and *A. Perry's White*, 282
 tomentosa, 31
 Wilcecki, 439
 Achimenes, 271
 coccinea, 450
 Aconite, the winter, 97; poisonous, 166
 Aconitum Napellus album grandiflorum, 461
 Adiantums with long stems, 424, 542
 Adonis amurensis, 81, 637; *a. fl. pl.*, 258
 planting the, 671
 the, 637; double Amoor River, 242
 vernalis, 637
 v. volgensis, 637
 Advice, questionnaire, 476, 526
 Ethionema iberidum, 299
 schistosum, 343
 Warley hybrid, 401
 Agapanthus, growing, 13, 469
 Ageratum seedlings, 419
 Agrostis pulchella, 38
 Almond, an early-flowering, 132
 the dwarf, 131; Russian, 132
Aloe ferox in bloom at Mount Henry, Dalkey, Co. Dublin, 617
 Aloysia citrodora in Scotland, 530
 Alpines, half-pots for, 594
 newly planted, after frost, 529
 Alstromeria aurantiaca, 336, 368
 seedlings, 374
 Alyssum alpestre, 55
 saxatile Tom Thumb, 276
 American-blight, 121, 616; on Apple-tree, 455
 Amicia zygomeris, 123
 Anagallis indica, 672
 linifolia, 672
 Anchusas, 281
 increasing, 618
 Andromeda japonica, 119, 155
 Androsace lanuginosa, 428
 Anemone apennina in a sunk garden, 237
 blanda, 249; *b. scythnica*, 201
 coronaria, 286
 demissa, 242
 fulgens, 402
 nemorosa Robinsoniana, 247, 295
 Pulsatilla, 228
 rupicola, 213
 stellata, 160, 227
 sylvestris, 320, 476
 the Poppy in winter, 67
 Anemones, Crown, 160
 the Scarlet and Poppy, 202
 Anemonopsis macrophylla, 196
 Angraecum eburneum, 272
 sesquipedale, 272

Angraecums, two fine, 272
 Annuals, 217, 249, 276
 summer, in the flower garden, 132
 the informal arrangement of, 388
 Anomatheca cruenta, 253, 644
Anopterus glandulosa, 357
 Antennaria dioica, 281
 Antholyza crocosmioides, 134, 155
 Antirrhinum Asarina, 350; *A. at Friar Park*, 373; *A., bicolor form*, 374
 Cottage Maid, 467
 gibraltarium, 381
 Antirrhinums, 84, 395, 441
 fungus on, 517
 in the flower garden, 499, 532
 Ants on Chrysanthemums, 437
 Aotus gracillima, 450
 Aphelexis humilis, 542
 Aponogeton distachyum, 408
 Apple Allington Pippin, 630, 666; *a failure*, 606; not fruiting, 540
 and Pear crops, 317, 376; and its future, the, 381
 Beauty of Kent, 286
 Bismarck, 108
 Bleuheim Orange, 110
 Bramley's, 131, 556
 branch, injury to, 108
 Carter's Pearmain, 240
 Claygate Pearmain, 230, 240
 crop, 1916, 519
 D'Arcy Spice, 124, 180
 Delicious from America, 110
 Dr. Harvey, 192
 Forge, 652

NOTES OF THE WEEK.

Pruning Clematis lanuginosa.—I cannot agree with "T.'s" instructions for pruning Clematis lanuginosa. I have a terrace wall, about 8 feet high, on which are twenty plants of Clematis Nelly Moser. Nearly every spring I cut them to within a few inches of the ground and obtain very strong shoots from the old wood. When they have grown about 3 feet I pinch out the leaders in order to obtain natural growth, and by this treatment I obtain an abundant mass of flowers twice in the year—namely, June and September.—L. H., Nuneham Park, Oxford.

The alpine-house.—I venture to think that the increased use of the alpine-house is to be deprecated. That such a structure is of use is admitted, but many of us—most of us, in fact—do not possess such a house, and while it may be handy for sheltering the finer and rarer alpine plants from rain and snow, it appears to be quite easily dispensed with in the case of Iris reticulata, I. r. cyanea, and similar Irises referred to in the issue of December 11th, p. 750, and which, with a little experience and knowledge of their requirements, can be grown equally well in the open.—KIRK.

Berberis subcaulialata.—This is a very attractive shrub, for, in addition to having a pleasing habit, it fruits freely and carries its berries well into winter. A native of Western China, it is one of many new kinds that have made their appearance during the last twenty years. In some places it may retain its leaves, or some of them, almost until new ones appear, whilst in other instances it may be quite deciduous. The branches are armed with numerous stiff but slender spines and clothed with small, bright green leaves. The yellow flowers are borne in clusters from the leaf-axils about June and are followed by small round fruits which, when ripe, are bright red. They are rarely at their best before the end of October, but hang for a considerable time in good condition.

Pears from Gunton Park.—Who shall say that we want southern valleys for growing good Pears when some of the finest we have seen come from Gunton? Among them there are superb specimens of Charles Ernest and Beurré Dubuisson, which Mr. Allan praises very much, and also President Barabé, which we are all getting to like. There is no doubt that over a large extent of our islands much fine fruit can be grown with success, and the moral is that we should not waste room with second-rate fruit and stewing Pears, or those only remarkable for size.

Saxifraga Burseriana multiflora.—Thanks to the courtesy of Mr. W. A. Clark, of York, I have at last received the information for which I was seeking, and am now enabled to give the history of this most interesting Saxifrage. Its parents were, as I suspected and suggested, S. Burseriana and S. Rochelliana (the pollen parent, however, was not the type S. Rochelliana, but its variety coriophylla). It was raised by the late Mr. Boyd, of Faldonside, Melrose—to whom we also owe S. Boydi and S. Faldonside—and was originally sent out by Backhouse, of York. How it got to impersonate a Burseriana is not clear, but it seems probable that it was sent out instead of a true S. Burseriana multiflora that the late Mr. Backhouse once collected and had sent out about 1889 or 1890. The hybrid is certainly one of the freest-flowering white Saxifrages of this section, and is well worthy of a distinctive name.—MURRAY HORNIBROOK.

French Vines for colour.—I have been an enthusiastic cultivator of Japanese Vines for some years now, and with a view to varieties I got some of our European or Grape Vines from France, with the beauty of which I am very much struck. They are more varied than the Japanese Vines, with all sorts of various colours on the same shoot. Wanting to know more about them I sent to Mons. F. Morel, of Lyons, who has kindly given me the names of the best kinds. They are grown under the general name of Teinturier. They are

Petit Bouschet, Alicante Bouschet, Gamay de Bonze, Gamay de Friant, Gamay de Moreau. He says they are all very hardy and the reddest in colour.—W.

Iris reticulata and I. r. cyanea.—A note in the issue of December 11th induces me to ask: Are conditions of soil and exposure studied when these and the earlier-flowering Irises are planted? I. reticulata and its varieties are frequently destroyed by an insidious disease which kills the bulbs in a short time, and from observation I feel fairly certain that this disease may be, almost entirely, prevented by the selection of a suitable site and exposure. Frequently this Iris is planted, with other bulbs, in a hardy plant border—very often exposed to the dangers arising from sodden soil in autumn and winter, and further handicapped by the shade of growing plants in spring when the ripening is being completed. Under such circumstances the vitality of the bulbs is weakened, and if disease should follow, the unhealthy bulb quickly succumbs. On the other hand, I. reticulata planted in light, loose soil at the base of a south wall will grow as freely and bloom as well as Iris stylosa, nor does disease appear to trouble the bulbs in such a position. If the shelter of a wall—whether the coping be of glass or merely of slates—can be given in addition, the blooms will expand clean and clear in colour.—KIRK.

The Mezereon (Daphne Mezereum).—This flowers at a time when outdoor flowers are welcome, its blossoms being at the same time showy and fragrant. Found wild in Europe and Siberia, it is occasionally found in a natural state in the British Isles, though it is much commoner as a garden shrub, especially in the North of England, where very fine bushes are frequently met with in cottage gardens. Very often it grows about 3 feet high, sometimes taller, and forms a shapely bush with vigorous, erect shoots. The flowers are borne from axillary buds on the previous year's wood, the whole shoot being a mass of bloom when at its best. As a rule,

the type and its white-flowered variety are at their best in February, but *D. M. grandiflora* commences to bloom in late autumn and is at its best about Christmas. Unfortunately, this particular variety is rather difficult to obtain, for it cannot be had true from seed as can the type and the white-flowered form. The colour of the flowers of *D. M. grandiflora* is reddish-purple, somewhat deeper than that of the type. It bears the familiar, rich scarlet berries of *D. Mezereum*, whilst *alba* bears yellow berries. Both the type and varieties give the best results in naturally moist soil and appreciate a little shade from hot sun.—D.

From Nice.—*Bignonia venusta* and *Bougainvillea Sanderae* are in great beauty with the Lamarque Roses growing in and out of them, and that wonderful winter-flowering *Acacia podalyriaefolia* is a sight just now. So with the Oaks, just in their autumn glory; we do not seem near Christmas. I really am writing to ask what you know about *Cupressus arizonica glauca*. I never saw it till the other day at Troncy's nursery near Cannes. It is a silver-grey, like an Olive (not at all blue), and on a dry hillside has a most beautiful effect with Aloes, Cacti, and grey-foliaged things, and "swears" horribly with ordinary Cypress and green things, so it would not look well in England, if it is known there. Coming from Arizona it wants a dry climate, even if it be fairly frost-proof. You never saw such strangling growths of wild Clematis, Brambles, and Ivy as I find in my valley after eighteen months' absence. I feel like Laocoon struggling with strangling, serpent-like coils of these monsters. In two more years my valley would be impassable, and at present I can get no labour save one nice young man not strong at all, but who loves his plants. Two years ago I planted some *Galanthus Fosteri* in the valley. They have thriven wonderfully and are now in very fine flower. It must be a southern form.—E. H. WOODALL.

Colour of trees in Britain and in New England.—I am very glad to get your interesting notes about autumn colouring of the trees. Your American Maple which loses its leaves is no doubt *Acer rubrum*, the only one of our species which seems to do well in England. Eastern American trees lose their leaves much earlier than European trees, at least that is the case in this country, the leaves of your European Elm, for example, remaining green long after those of the American species have entirely disappeared. The leaves of most Japanese trees and shrubs turn in this country as well as those of our native plants of the same genera, but a month later, and we are finding now that the leaves of many of the new Chinese trees and shrubs remain green even later than those of Japanese plants. As this is not a country of broad-leaved evergreens we particularly value trees and shrubs which retain green leaves late in the season. One of the most distinct of these is your European Privet, which is a much better plant than any of the now more popular Japanese and Chinese species. Nothing here has been so handsome, perhaps, lately, as Wilson's *Lonicera Maacki podocarpa*, which retains green leaves very late, and is still covered with bright scarlet fruits. I hope this plant does as well in England as it does here. On the whole, however, the best crop of Wilson's plants for us here are the Cotoneasters, and among them the finest species, I think, is *C. huphensis*, the handsome shrub, from our point, of all Wilson's discoveries. — C. S. SARGENT, *Arnold Arboretum, Mass.*

FRUIT.

ROOT-LIFTING AND ROOT-PRUNING.

FIRST as to root-pruning, the object of which is to check over-luxuriance. This check is best given by lifting the trees, laying the roots out in a horizontal position nearer the surface. In a well-balanced tree the roots should about balance the branches, and the most active roots are within a foot, or less, of the surface. If there were less branch-pruning there would be less need for root-pruning. Often our restricted systems of training render necessary some check being placed upon the roots in the case of wall trees and espaliers. In the old days this was met in some instances by an impervious base immediately under the tree, generally in the shape of concrete. If young trees were lifted when four years or so planted, and the roots properly laid out, the advantage would be great. Every gardener I have known seeks to obtain the control of the roots and keep them near the surface under the influence of the sunshine.

Of course, there are soils and positions so favoured that one cannot go wrong. On the other hand the wise man studies the roots as well as the branches. Take the case of the Fig. In many parts of the country, if we lose control of the roots we get no fruit, and perhaps in a less degree in the case of the Vine and the Peach. On clayey, badly-drained soils, station planting, which consists of an impervious base 3 feet or so square, or round, which arrests and turns aside the tap roots, is necessary. All badly-drained land should have drains at necessary intervals not less than 3 feet deep, especially for fruit culture. Shallow drains are useless on fruit land as they ultimately become blocked by roots.

E. H.

MISTAKES WITH CORDON PEARS.

THE cordon system of Pear culture has increased very considerably of recent years, and the trees, as a rule, are fairly well done, but mistakes are made, especially by amateurs, who probably often plant before making themselves conversant with the several points essential to success. Among the mistakes, perhaps the most frequent and noticeable are shallow planting, indifferent selection, and summer pruning. A certain amount of preparation of soil is essential before planting, which is often done before the ground is thoroughly settled, thus exposing the collar of the tree and the top roots. If this happens, the remedy is to prepare a certain amount of soil, the greater part a rather heavy loam with a small portion of thoroughly decomposed manure, putting it on as a mulch of sufficient thickness to come just above the planting-line of the tree. In the matter of

SELECTION there is first the question of the varieties that do well on the Quince, then the choice of the best sorts, and lastly (whether the collection is on a large or small scale) the question of season. Too many varieties of the same season are not required, as Pears, with few exceptions, are short-lived after approaching the ripening stage, and it seems a pity that fruit of high-class quality should be wasted. One of the exceptions from a keeping standpoint is *Glou Morceau*, which, if slightly advanced or retarded before or after its natural ripening season, can be had in first-rate condition for several weeks. This and *Marie Benoist*, *Nouvelle Fulvie*, and *Josephine de Malines* are about the most satisfactory late Pears as cordons. Another mistake, and one

highly prejudicial towards securing an annual crop, is in connection with

SUMMER PRUNING or pinching. This, with an idea towards the neat appearance of the trees, is often done far too early, with the result that a lot of weak growth that is absolutely worthless follows, and which has to be cut clean away later in the season to secure a sturdy back-break, meaning the loss of a part of the crop for a couple of seasons. No exact time can be fixed for the work. It will vary in different seasons according to atmospheric conditions and as early or late growth is made. The start should be delayed until the wood of the shoots from the base upwards is getting a bit firm and showing signs of a change of colour towards the ripening stage. In the case of varieties inclined to make a lot of growth it is as well to retain a few well-balanced shoots at occasional intervals the length of the trees; these can be tied in loosely if the weather is rough to prevent the danger of snapping at the base, which sometimes happens with strong, succulent growth. There is also a considerable difference in the manner of growth in different varieties so far as the first formation of shoot and spur on the main stem is concerned, and if the spurs are very thickly set and blossom is freely produced at the expense of growth it is sometimes advisable at the winter pruning to remove every other one of such spurs, not too hard in to the main stem, but sufficiently so that a nice strong break, that can presently be treated for the formation of a fruiting spur, comes away.

E. B. S.

Hardwick.

NOTES AND REPLIES.

Failure of Gooseberries.—I have a number of cordon Gooseberries which have for some years been bearing very good crops. Some of them are single cordons, others double, and others treble. For the last few years I have been much troubled because each year a certain number of these trees loses entire branches, which die away in an unaccountable way. It looks like a sort of canker. Can you tell me the cause and cure? I may add that the trees are sprayed every winter with the caustic alkali wash.—C. J. L.

[The dying of the branches on the Gooseberry-trees in the question is, we think, due to the agency of the caterpillars of the clearwing moth. These gain ingress to the shoots or branches through one of the buds situated on the same, and from where they tunnel upwards and downwards, destroying the pith in so doing and ultimately causing the death of the said shoots and branches. The very fact of the attack being set up in the manner briefly described renders remedies in the shape of insecticides and caustic washes of no avail. As a rule, their presence is usually denoted by the leaves on the affected parts beginning either to wilt or assume a sickly or unhealthy appearance, and if these pieces of wood are at once removed, cutting them back to where the leaves are quite healthy and normal, the infestation can be, to a great degree, lessened. Both these affected pieces of wood as well as prunings should be burnt. By paying strict attention to the timely removal of the infested shoots as indicated above you should in the course of a season or two get rid of the trouble.]

Red Currants shrivelling.—In a garden of which I have charge I have Red Currants round one square, and last spring all the fruit bunches on the trees on two sides of the square shrivelled up without any apparent reason, while on the other sides the fruit developed all right. I want, if possible, to prevent this happening again next spring, and shall be obliged for any help.—C. J. S.

[This, no doubt, was due to caterpillars of the Currant shoot and fruit moth. The latter deposits its eggs in the young fruit and the caterpillars, when hatched out, render it useless. This same pest is

also a pith-borer, and the best means of circumventing it is to be on the alert and remove every shoot and piece of wood exhibiting the slightest sign of being infested, indication of which will be given by the wilting of the young leaves, and burning them. Also be very careful to remove and burn all prunings at the present time, and keep the soil beneath the bushes clear of any kind of rubbish in the shape of dead twigs, etc., at all times. When pruning is going on carefully scrutinise the two-year-old wood and cut back any portion found in a dead or dying condition to a point where it is sound and healthy. Insecticides and caustic washes are, as in the case of dealing with the caterpillars of the clear-wing-moth, useless.]

Pear Durondeau not ripening.—For the last three years my Durondeau Pear has not

for planting—August for preference—there are sometimes reasons for delay, and then March, or very early in April, offers the best chance. If the land is not in good condition no time should be lost during January or February in trenching and manuring. Allow time for settlement before planting, as firmness is essential for Strawberries, the opposite often leading to blindness. I have seen in the past Onions planted between the Strawberries and very profitable crops raised. The Onions were raised under glass in boxes in January, hardened off in cold frame, and planted out early in April 6 inches apart in alternate rows with the Strawberries. All the work required afterwards was clean culture by hoeing, and perhaps a light mulch of manure. There may be only a light

TREES AND SHRUBS.

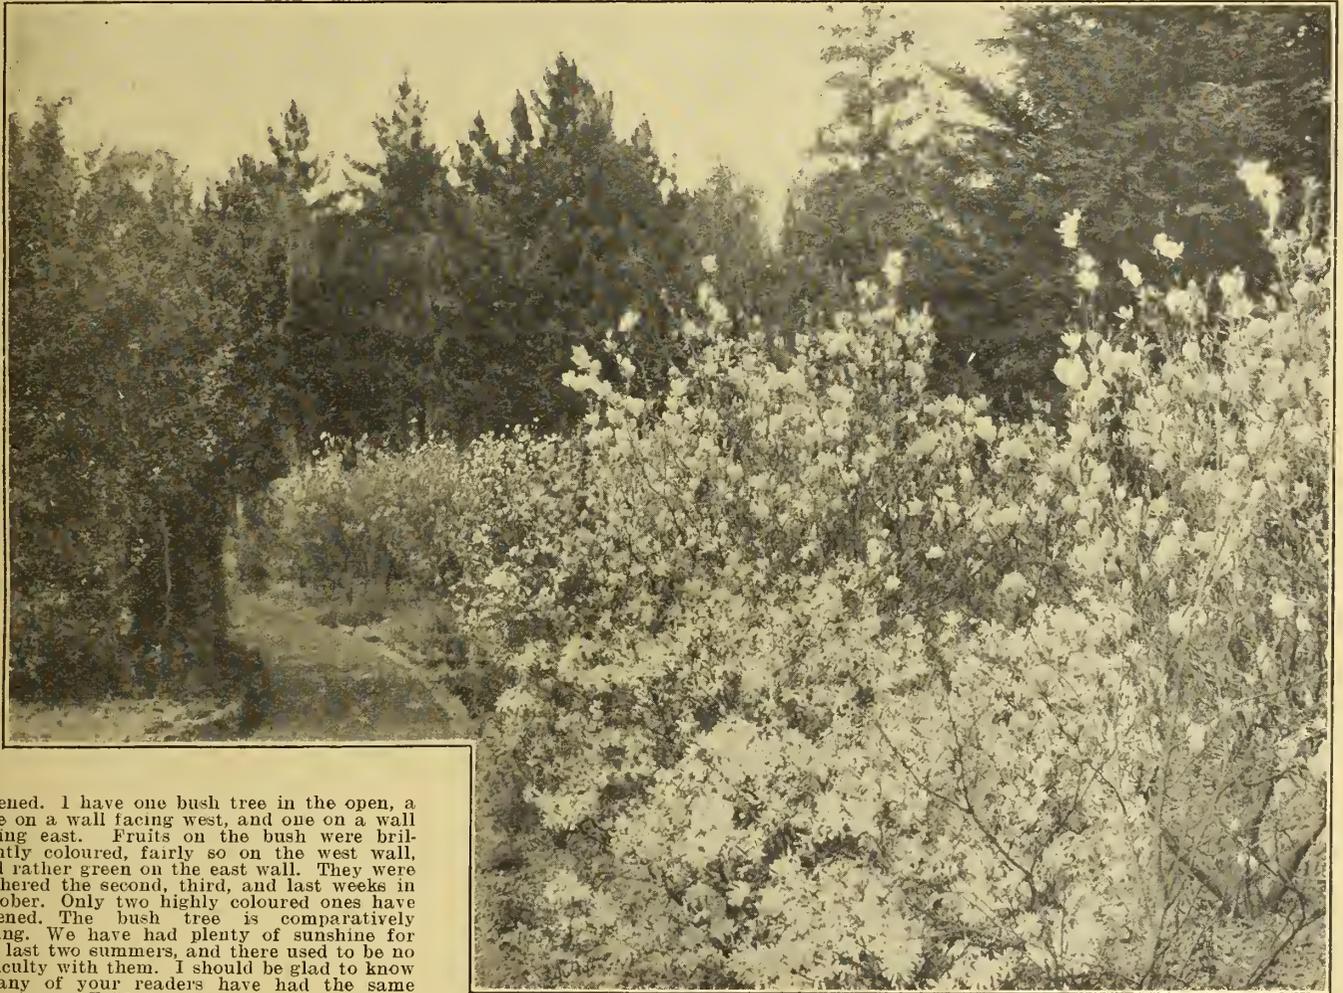

THE STAR MAGNOLIA.

(*M. STELLATA*.)

This is a very free and hardy kind, and easier, I find, to grow than most sorts in cultivation. Here I have it especially effective in the foreground of a group of taller Magnolias, with a background of Pines. The soil is cool and rather heavy, but this Magnolia does not seem to fear the conditions. W.

SOME ORNAMENTAL FRUITS IN DECEMBER.

ALTHOUGH the weather of the past two months has not been particularly favourable for the outdoor garden, many attractive fruits are still to be found in good

Magnolia stellata and others. Gravetye.

ripened. I have one bush tree in the open, a tree on a wall facing west, and one on a wall facing east. Fruits on the bush were brilliantly coloured, fairly so on the west wall, and rather green on the east wall. They were gathered the second, third, and last weeks in October. Only two highly coloured ones have ripened. The bush tree is comparatively young. We have had plenty of sunshine for the last two summers, and there used to be no difficulty with them. I should be glad to know if any of your readers have had the same experience.—F. M. G.

[The Durondeau Pear is on some soils but half melting, or, in other words, the flesh is inclined to be rather crisp-eating; but as yours have till within the last season or two ripened perfectly, we think the reason for their not doing so since must be due to the roots having gone down into the subsoil. Under the circumstances, we can in no other way account for the trouble. The remedy is either to root-prune or to lift the roots, preferably the latter, unless the trees are too large to be thus dealt with, and to lay them out afresh in a nearly level position, placing some fresh loam of a fibrous nature and a small quantity of wood-ashes about them before returning the ordinary soil thrown out in the process of searching for the roots. The roots will thus be brought nearer the surface and under the influence of solar warmth, conditions which should remedy the evil complained of.]

Strawberries, spring planting.—Even admitting that the autumn is the best time

crop of Strawberries the first season, but the crop of Onions will be a compensation, and in the second year the Strawberries will occupy all the ground and will produce abundantly. The following are good varieties:—Royal Sovereign, Sir J. Paxton, Reward, and Givon's Late Profitic.—E. H.

Thinning out old Currant-bushes (E.).—In the case of the Red Currants, some of the old branches, if they cross each other and are very thick, should be cut out entirely, and the side shoots left on those should be spurred in to two or three eyes, like a Vine, the leading shoots being left 6 inches or 8 inches in length. The Black Currants bear on the young wood, therefore thin out the bushes by removing as far as necessary the old cross branches, and let the young wood be left in at full length, and not too thickly. If you could get a good gardener in the neighbourhood to show you how to prune the bushes it would be a great gain to you.

condition. Particularly beautiful are the bright red berries of *Cotoneaster frigida*, borne in large clusters from long, slender branches, and few shrubs fruit more freely. A bush 15 feet or more high or a small, well-branched tree add greatly to the general effect of a garden. As a rule, birds commence to eat the berries in November, but this year they have escaped. Another very beautiful *Cotoneaster* is *C. rotundifolia*. The bright red berries of this usually hang until March, birds for some reason leaving them untouched whilst food of any other description can be procured. The orange-coloured berries of the Sea Buckthorn (*Hippophae rhamnoides*), though somewhat bleached by frost, are still attractive. Anyone planting this shrub must be careful to procure both male and female plants, otherwise there will be no fruits. As a rule, one

male may be planted amongst six females. The *Pyraecanthas* form another attractive group, in this case bright berries being mingled with evergreen leaves. *P. coccinea* and *P. crenulata* have rich scarlet berries, and *P. angustifolia* orange-coloured fruits. The last-named is more tender than the others, and even in the south of England should be given wall culture. The others are usually grown against walls, but give quite good results in the open ground. Unfortunately, if the bushes are not netted the fruits are soon taken by birds. The Siberian Crab (*Pyrus baccata*) is a very desirable tree for its freely-borne red fruits are conspicuous from a great distance and often hang until March. *Pernettya mucronata* bears large numbers of berries which may be of various shades of colour—red, purple, lilac, or white, according to variety. *Celastrus articulatus* is a vigorous climber with yellow fruits enclosing orange-scarlet seeds. *C. scandens* bears similar fruits. The various *Hollies* are, of course, very beautiful now, particularly the common *Ilex Aquifolium* and the American *I. opaca* with bright red berries; also the yellow-berried form of *I. Aquifolium*. The deciduous Holly *I. verticillata* is also most attractive now, its thin, wiry shoots being festooned with small, coral-red berries. A few days ago two Thorns, *Crataegus Carrierei* and *C. cordata*, were still covered with fruit, whilst several kinds of *Pyrus* of the Aria group were also effective. The berries of the common Mistletoe are effective in many places, but the fruits of the Snowberry (*Symphoricarpos racemosus*), which usually remain good until the New Year, have been turned yellow by frost. D.

NOTES AND REPLIES.

Halesia tetraptera, var. monticola.—The Silver Bell-tree of the southern States, *Halesia tetraptera*, has long been cultivated in northern gardens. It is usually shrubby in habit with several stout, wide-spreading stems, and here in the north rarely grows more than 15 feet to 20 feet high. It is an inhabitant of the southern States from West Virginia to southern Illinois, northern Florida, and eastern Texas. It grows at low altitudes, and does not appear to ascend to the slopes of the high Appalachian mountains, although the *Halesia* of those mountain forests was long considered identical with the lowland tree. The *Halesia* of the high slopes, however, is a tree often 80 feet or 90 feet high, with a trunk 3 feet in diameter, sometimes free of branches for a distance of 60 feet from the ground. It is apparently only in recent years that this mountain tree has been introduced into cultivation. The mountain tree which has lately been distinguished here as *var. monticola* grows as a tree from the time the seed germinates and the seedlings show no variation of habit. Young trees are clean stemmed with short branches which form a narrow pyramidal head. The leaves are of rather different shape and less hairy than those of the lowland tree; the flowers are fully a third larger and the fruit is nearly twice as large. Trees less than 10 feet high produce flowers and fruit freely. There is now every reason to believe that the mountain *Halesia* will prove one of the handsomest flowering trees of large size which it is possible to cultivate in this climate. Its tall trunk and narrow head suggest that it may prove a good street and roadside tree.—*Arnold Arboretum Bulletin*.

Hardy Heaths.—This is a very large family, but they are exceedingly beautiful and interesting to fill suitable positions in the rock garden or to form broad edgings round masses of shrubs. If a good selection is planted, some may be had in flower nearly all the year. Sandy soil seems to suit them best.—E. H.

PLANTS AND FLOWERS.

ROSES.

PRUNING CLIMBING ROSES IN COLD-HOUSE.

Will someone kindly tell me the proper time for cutting back and pruning Roses the roots of which are outside? The house is kept rather cold. I grow *Maréchal Niel*, *Niphetos*, and *Mrs. W. J. Grant*. By-the-by, the foliage of these Roses invariably gets very black and dirty after, say, June, in spite of fumigating and syringing, which I find spoil pot plants, such as *Zonal Pelargoniums*, below them.—*BRENTWOOD*.

[The best time to prune such varieties as you mention is about June—after flowering is over—when it is advisable to cut away any old wood that has apparently done its work. This will cause the plant to throw up plenty of young growths for next season's flowering, provided the roots are in rich soil, or are supplied with nourishment from the surface. The production of these young rods will be encouraged by keeping the house rather close and supplying plenty of moisture during early summer, gradually hardening them off in late summer and autumn by giving more air. Any further pruning that may be necessary should not be done too early or new growths will be forced and will probably be nipped by any severe frosts that happen to come. The beginning of February is about the best time to cut in the lateral growths, etc. To encourage early flowering every bit of sun heat should be shut in during February and March.

The dirty appearance of the leaves after June is probably caused by the presence of aphids, and it is only possible to get rid of the nuisance by spraying with an insecticide. Much of the dirty foliage would be removed if the older wood were pruned away after flowering, as recommended. It is most difficult to grow Roses successfully indoors when other plants, such as *Pelargoniums*, have to be placed in the same house, for Roses need special treatment which will not suit other subjects.]

NOTES AND REPLIES.

The Macartney Rose (*Rosa bracteata*).—In the autumn of 1893 I procured a plant and placed it at the foot of one of the pillars of a pergola. That winter the mercury showed 20 degs. of frost on two consecutive nights, but the plant was unharmed and threw out shoots 5 feet in length the next summer. The next winter was the severe one of 1894-5, when for many weeks in the early part of the latter year the ground remained frost-bound. The Rose was absolutely unprotected, but with the return of more genial weather it burst into fresh growth and subsequently flowered well. Seeing that this Rose had no wall-protection it may be claimed to have successfully withstood a tolerably trying ordeal. However, it may not be sufficiently hardy to warrant its being recommended for trial in any exceptionally cold district, even if given wall-protection. It is largely grown in the south-west, where many fine specimens exist. One of its chief charms lies in the length of its blossoming season. It rarely commences to bloom before the end of June or beginning of July, but from that time until November it continues to produce its single white blossoms. The individual flowers remain attractive for about two days, and are produced in rapid succession, good plants often carrying from four to five dozen expanded blooms at the same time. In comparison with Roses, whose flowering season is short-lived, this number may appear insignificant, but it must be remem-

bered that this average is often kept up for fifteen weeks or more. Its dark, glossy foliage is practically evergreen.—*WYNDHAM FITZHERBERT*.

Rose Coronation.—Many of the Roses to which the National Rose Society has awarded its Gold medal fail to prove worthy of this distinction, but in the H.P. *Rose Coronation* we have a noble addition to the Gold medal Roses. It is one of the largest Roses yet raised, but is so well formed that there is not the slightest suggestion of coarseness about it as is so often the case with very large blooms. The flower is very solid, the firm, thick petals enabling it to open perfectly in the dampest weather. Its form is perfect. The colour is lovely, the bright shrimp-pink of the young flowers fading to a soft silvery pink as they expand. The wood is extra stout, the plants sending up great limbs upon the top of which the flowers are borne quite erect. This Rose will also be useful in the garden, and may be grown in the form of a pillar or against a wall or fence.—*EGLANTINE*.

Rose Mrs. Wakefield Christie Miller.—There are many Roses now in cultivation which flower right into the winter, but there are few that can surpass *Mrs. W. Christie Miller* in this respect. My plants have been in flower right from June until now (December 10th), and it is the most effective variety I have had in bloom during November and December. The buds are of a very rich deep rose, fading a trifle as the flowers expand, when the soft pearly-pink on the inner side of the petals is revealed. The form could hardly be called ideal, as the petals are very short and ragged at the edges, but the blooms are of good size and fairly substantial, the curious overlapping and incurving style of the petals causing them to hold together for a very long time. Many present-day Roses are extremely fleeting because of their thinness, while most of the more solid varieties have the unfortunate habit of hanging their heads. In this Rose we have one which holds its flowers perfectly erect on good, firm stems, thus showing them to the best advantage. The growth and habit of this Rose, too, leave nothing to be desired, each of the shoots producing a succession of fine flowers. No weather seems to harm the blooms, the substantial petals withstanding quite severe frosts. I have not yet seen any signs of either mildew or black-spot on this variety.—*EGLANTINE*.

Rose Farben Konigin.—This is one of the finest Roses I have seen this autumn, and it is strange it is not more widely grown. The name, which literally means Queen of colours, is very apt indeed, for the colour of the blossoms is very distinct. The buds and young flowers are bright red, the colour of the older blossoms changing to clear pink with deep pink in the centre. The blooms are showy right from the bud stage until the petals drop, the colour particularly during the autumn being very bright. *Farben Konigin* is a vigorous grower of the *La France* type. Not only is the habit very free, but the flowers are produced in abundance throughout the season. For grouping, *Rose Farben Konigin* has few equals. A valuable characteristic of this Rose is its sweet scent.—*EGLANTINE*.

Climbing Rose Lady Godiva.—Of several charming flesh-pink sports from *Dorothy Perkins*, still one of the most popular of the *Wichuraiana* climbers, it may be said that they are much alike. *Lady Godiva*, *Dorothy Dennison*, and *Christian Curle* are all so near each other that one may well grow one only. I grow the one exhibited at the Temple Show of 1906 as *Lady Godiva*, and every year it grows in my estimation. In the garden it is lovely, while its delightful flesh-pink flowers are very useful for cutting for the house.—*SCORCH ROSE*.

INDOOR PLANTS.

RHODODENDRON GRIFFITHIANUM (SYN. R. AUCKLANDI) AND ITS HYBRIDS.

RHODODENDRON GRIFFITHIANUM is one of the finest members of the family, but being tender, and requiring a good-sized structure for its development, it is uncommon. Though unsuited for outdoor culture everywhere, some of the several hybrids raised from it are quite hardy and valuable from their distinct character. Such an one is

PINK PEARL, of which *R. Griffithianum* is one of the parents. The flowers of this, which are borne in somewhat loose

clear rose, which latter is almost crimson when in the bud state. In all of these the flowers are shallow and the trusses loose, as in the typical *R. Griffithianum*. There is undoubtedly a great future before the members of this group, but up to the present they are scarcely to be obtained from nurseries.

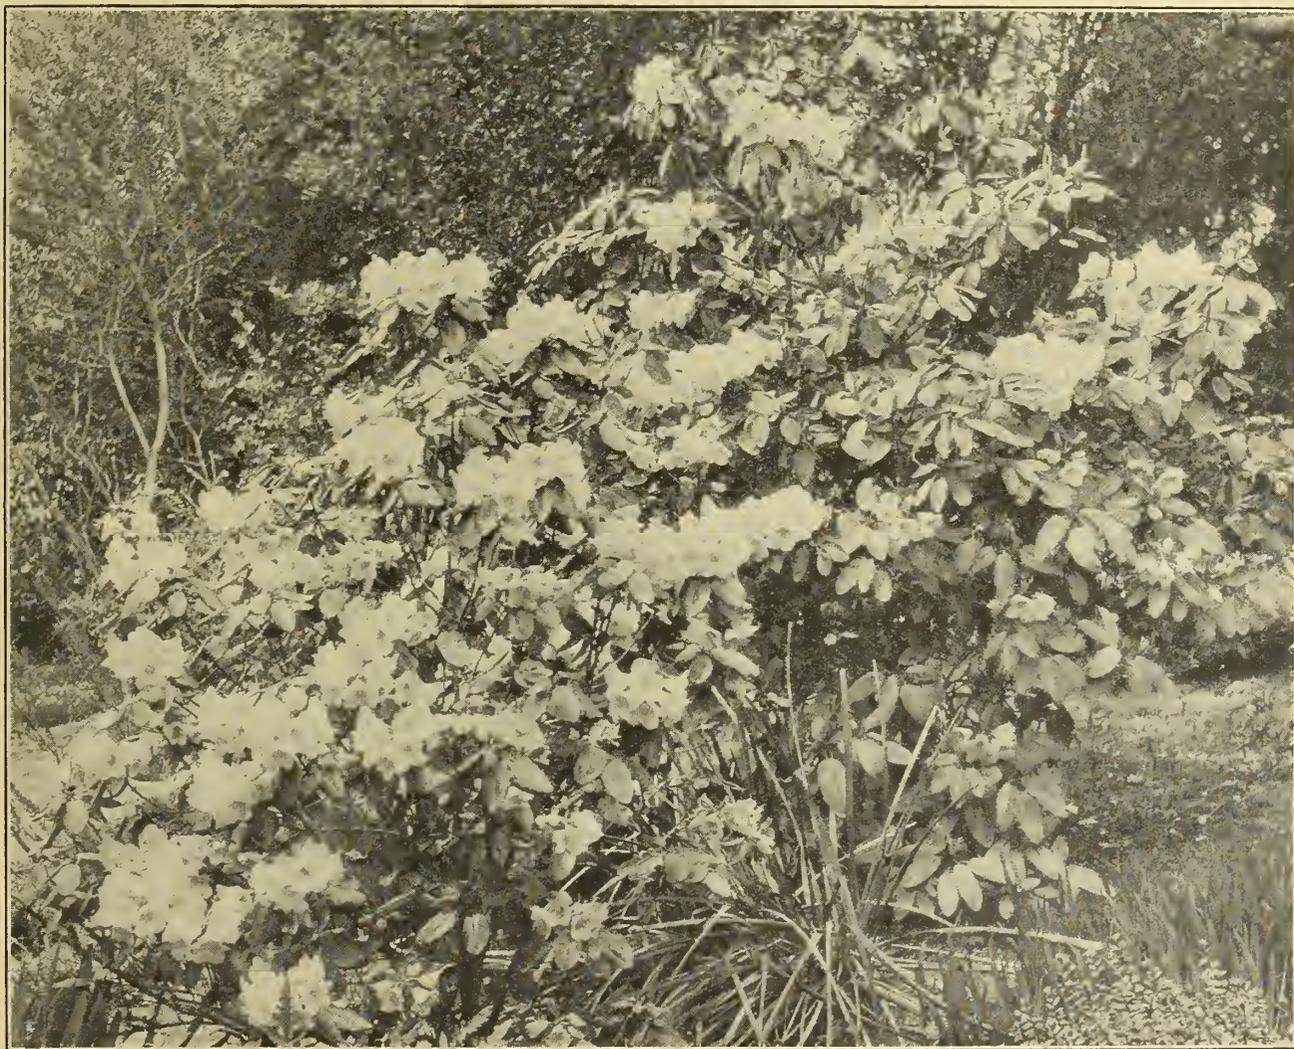

R. MANGLESII was raised by Messrs. Veitch and Son between *R. Griffithianum* and a garden form known as *album grandiflorum*. It is a very pretty variety, whose saucer-shaped blooms are pure white, except a few reddish spots on the inside.

R. LODERI was raised at Leonardslee between *R. Griffithianum* and *R. Fortunei*. This, in its large leaves and flowers, bears

able whether it is wise to allow them to remain too long in the boxes before potting them. As a rule, far too many cuttings are placed in one box at first, with the result that crowding results. Where plants are given a fair amount of room in boxes, one can begin to cut them down in spring and strike again in the warmth of a propagating bed. I find that a shelf near the greenhouse roof is the best place, as there the plants do not become unduly drawn.—WOODBASTWICK.

LILIUMS.

THE best of the bulbs of *L. lancifolium* *Krätzeri* and *L. l. rubrum*, which last season were grown in pots for greenhouse decoration and other purposes, are now in fit condition for shaking out and repotting.

Rhododendron Griffithianum in Mrs. Chambers' garden at Haslemere.

trusses, are individually about 4 inches across, and of a delightful shade of clear rose-pink, with but a few small brownish spots upon the upper segments. This was raised and distributed by Messrs. John Waterer and Sons, of Bagshot, and was first shown by them in the spring of 1887, when it was given an award of merit by the Royal Horticultural Society. Three years later this was increased to a first-class certificate.

R. KEWENSE.—A beautiful series of hybrids between *R. Griffithianum* and *R. Hookeri* was raised at Kew, and the different members have proved to be perfectly hardy there. To this group the collective name of *Kewense* has been applied. In these different forms the flowers vary from pure white to a deep

a great general resemblance to *R. Griffithianum*. The blooms, however, are borne in bolder trusses and are pure white in colour, though in the buds there is a pinkish suffusion.

Their cultural requirements in no way differ from those of the other garden forms of hybrid *Rhododendrons*—that is to say, a fairly moist soil, containing at least a good proportion of vegetable matter, while if they can be planted so as to be partially sheltered from spring frosts so much the better, as *Kewense* at least is rather apt to start early. T.

Bedding plants in boxes.—A great number of bedding plants are now grown in boxes, but after Christmas, when the young plants begin to grow, it is question-

This is best done before new roots are emitted. The bulbs not deemed worth growing in pots again come in useful for planting in groups in the flower borders. These, now about to be potted, will flower in advance of the imported bulbs which will shortly be coming to hand. After having been potted they will, from want of room at the present moment, be placed on a vacant shelf in the fruit-room. As but little water is required until they start growing, their being placed here will not in any way prove objectionable or occasion inconvenience. Thoroughly clean pots are necessary, which should be well drained. Good fibrous loam in the proportion of two-thirds with one-third leaf-mould with a liberal quantity of coarse silver sand is the compost employed.

When the leaf-mould is in a very decayed condition a small quantity of spent Mushroom dung is added. A little sand is placed at the base of each bulb to encourage early rooting, the bulbs also being kept low enough down in the pots to allow of a top-dressing of the same kind of compost being added when growth is in full vigour. When the bulbs are well rooted and growth begins to push up they will be removed to a cool greenhouse. New bulbs as soon as received will be potted in the same kind of compost and placed for a time in the fruit-room with the others and eventually in a pit. G. P. K.

Shrubs for forcing.—Where shrubs intended for forcing are not already established in pots they should be potted directly the leaves fall. If this is done and the pots plunged up to the rims in leaves or some protective material the plants will, if carefully watered, become established before it is necessary to take them indoors. It will be found that the more thoroughly the plants are established before they are subjected to forcing so much the longer will the flowers last. This applies more especially to shrubs with a limited number of fibrous roots, such as the Almonds, Pyrus, etc., than it does to members of the Ericaceæ, Azaleas for instance, as their hair-like roots are so numerous and of such an interlacing nature that each plant carries a large ball of earth. The chief difficulty is to get them into a pot of moderate dimensions without unduly distressing the roots. Another point of importance in the forcing of shrubs, and, indeed, plants of all kinds, is that they should be gradually inured to a higher temperature instead of being introduced all at once into a warm structure. It is very essential, too, that after forcing has commenced they are at no time allowed to suffer from want of water.—W. T.

Lindenbergia grandiflora.—Introduced somewhere about the middle of the last century, this would appear to have been lost to cultivation, or nearly so, till a dozen years ago, or thereabouts. Since then it has cropped up here and there, but at the same time it is far from common. It was within the last three or four years given an award of merit by the Royal Horticultural Society. This Lindenbergia is a somewhat straggling sub-scandent herb, that needs to be stopped freely when young in order to ensure a bushy specimen. The bright-yellow flowers suggest those of a large form of Musk, and being borne for some distance along the shoots they make a goodly show. A succession is kept up for some time. Cuttings can be readily struck during the spring, while the old plants may be shortened back and grown on a second season. Good examples may be had from 18 inches to 4 feet in height.

Cinerarias.—The earliest plants are developing their flower-heads, and are afforded plenty of stimulants. A number of the more forward specimens has been placed in a warm house, where they will bloom very early.—F. W. GALLOP.

Dracæna Goldieana.—This is quite distinct from all the other members of a numerous family. Its stem is erect, and the foliage stands out almost at right angles, its mottled leaves being banded with green and grey bars. The reverse of the young foliage and the tip of the stem are of an attractive reddish hue, and well-grown pieces are useful in many ways. *D. Goldieana* can be grown in a warm greenhouse; but the temperature of the stove is more suited to it.

Canterbury Bells in pots.—One may have quite a brilliant show of bloom in the spring in a cool-house by potting up now Canterbury Bells from seed sown last May. I find if they are potted up in the late autumn into 5-inch or 6-inch pots and placed under glass—a cold-frame will answer the purpose for a couple or three months—and afterwards brought into the house they will give a deal of pleasure at a very trifling cost.—TOWNSMAN.

GARDEN FOOD.

NOTES AND REPLIES.

The Ribston Pippin.—I have just had a good sample of this from Mr. Thorburn, of Upton Cross, Chester, who grows it very well as a standard; and why should not many do the same with this grand old Apple? The enemies of it most visible about my district are the American blight and canker, which with our present knowledge we ought to be able to abolish if we begin with young healthy trees. Old warty trees are better on the fire. Canker can be kept away by washing the healthy young trees with the usual mixture, and no trees should be sent out that are not absolutely free from American blight. A nursery in which the trees are infected with American blight should be avoided altogether. The Ribston is the best Apple we have for eating and keeping, and, as I maintain, for cooking. The thing is to get it into good health and fertility.—W.

Baked Potatoes.—Potatoes for baking are very poor this year. My own, which I usually always bake with pleasure, have turned out so bad that I wrote to Messrs. Judd and Malin, the well-known Jermyn-street salesmen, to whom I go when I want a good baking potato. They wrote me as follows, and offer a dismal prospect for the winter:—

“We have a few British Queen that cook really well, but find the utmost difficulty in getting any quantity of really good stuff. The late frost and second growth have spoilt the quality of the Lincolns. The Dunbars are of large size, but diseased, and of inferior quality. It is possible that, as there is an idea current that Potatoes will reach a high price, farmers may be holding anything really good.”

Brussels Sprouts, right way with.—I hope that no reader will go too far in trying to use nearly every leaf of her Brussels Sprouts. Some cooks merely remove those leaves which are actually diseased, and, after cleansing the Sprouts in salted water, proceed to boil them to death and to serve them discoloured and sodden like baby Cabbages that have been racketing about all night. The proper way is to trim them until only the firm and hard part remains, which should be like a handsome, closely-grown, miniature Cabbage, about the size of a walnut. They must be put into salted boiling water, or, better still, into a perforated steamer over boiling water, and cooked until, without losing their firmness, they have become tender. Half-an-hour of boiling or steaming will generally be enough. If they are to be eaten with meat and gravy they will be simply drained dry and served hot. If, however, they are required to accompany some rather dry meat, or to be eaten as a separate dish, you must put them back into the saucepan, having first melted therein 1 oz. of butter to every pound of Sprouts. The butter must be very hot. The pan is kept by the side of the fire or over the smallest gas-jet and is shaken now and then during six or seven minutes. The saucepan remains uncovered from the beginning to the end of these operations, even during the first boiling. If you should boil the Sprouts in a closed saucepan they would not keep their pleasant colour. If Brussels Sprouts are lifted out of the pan or steamer before they are quite tender, and are dried with a cloth and dusted over with salted and peppered flour, they can be fried. Each Sprout must be dipped in a mixture of egg and bread-crumbs till it is coated all over, and the frying must be true frying in boiling

fat at least 2 inches deep. As always with fried tit-bits, the Sprouts must be drained on paper and not a moment must be wasted in piling them on a very hot dish and sending them straight to the table.—*Home Cookery in War Time.*

Winter salads.—I had given up salads with the going of the various Lettuces, and now (end of November) enjoyed an excellent one of another sort, a mixture of a crisp Celery and Newtown Pippin Apple, both cut into small bits, with a few small pieces of Beetroot. Another excellent winter salad is of Lamb's Lettuce and Celery. Lamb's Lettuce should be more often grown.—W.

Red Cabbage with Apples.—Take a medium-sized Red Cabbage. Clean, cut into quarters, cut across into very thin strips. Cut up two medium-sized crisp Apples. Have ready a thick saucepan, preferably of French earthenware, put in a tablespoonful of butter or dripping (cold), add Cabbage and Apples, put on the stove, and let it cook very gently until Cabbage is tender. No water is needed if cooked slowly. A little Lemon juice, which many think an improvement, may be added if liked.

Standard Pear-trees.—In many gardens the fruit from these is of much higher flavour than from walls. In my own garden I have standards 16 feet high of Beurré Hardy and Louise Bonne of Jersey. This year the crop was good and extra clean, of good size, and of the best flavour. From a tree of Doyenne du Comice that had been grafted on Beurré Diel the fruit was delicious. I have now Glou Moreau from a standard tree, each fruit weighing about 6 oz., and of the best flavour and equal to those from wall trees. This year none of the fruit cracked. These trees are on the Pear stock, on which they thrive far better than on the Quince.—WEST SURREY.

Storing Apples.—I am convinced more fruit is spoilt from over dryness than from damp. Placing the fruit on wooden shelves is very unwise where the air is dry. I should prefer to put them on the floor and cover them. Shelves answer in sheds, cellars, etc., where the air is moist. I prefer to cover them against frost to giving artificial heat. Storing in boxes, barrels, etc., has much to recommend it. “W. S.” mentions having seen them stored in this way by me many years ago, when at Forde Abbey. Since I have lived in Surrey I have used nothing else, and have had a continued supply from end of July till mid-summer, finishing with Sturmer Pippin. I have nothing but an iron shed to keep them in at any time, and use no artificial heat in the severest weather. “W. S.” does well to point out the advantage of late gathering and using paper instead of straw, etc.—J. CROOK.

Food in France.—The poorer middle classes, the aristocracy which has not gilded its coat of arms with plebeian gold, and a large proportion of the working classes have reduced their kitchen expenses very thoroughly since the war began. Meat once a day is the rule, not the exception, and simplicity is a marked feature of every meal. The early breakfast of tea or coffee with rolls and butter (such excellent butter) is followed by a mid-day lunch of three courses—a dish of Rice or macaroni, a meat and vegetable course, cheese and fruit. In the evening comes a good vegetable soup, a dish of eggs, vegetables or one of the many varieties of macaroni flavoured with an appetising sauce, and then a compôte of cooked fruit.—*The Times.*

A delicious oatmeal gruel for children and grown-ups.—Take half milk and half water the quantity required. When boiling, sprinkle in gradually enough medium Scotch oatmeal to make a gruel, not too thick. Add a few Prunes and Raisins. Let boil until the oatmeal is done (about three-quarters of an hour); just before serving add a few blanched Almonds. One or two sticks of Cinnamon put in with the Prunes and Raisins improve it if Cinnamon flavour is liked.—H. O.

Cooking Celériac.—Will some reader give a few hints as to the best ways of cooking Celériac and the means of preventing it turning a dark colour in the process?—A GARDENING COOK.

OUTDOOR PLANTS.

A GARDEN PORCH.

This is my garden porch. It was designed by Sir Ernest George in the simplest way. The pillars and walls are of sandstone and the roof is of old Horsham stone. Having built it I threw some Houseleeks on top, where they all seem happy enough without attention of any kind.

W.

SOME STORM-PROOF PLANTS.

It is surprising the number of plants there are—even at the end of October—which have braved the cold nights and are still giving touches of brilliant colour. One of the brightest corners we have is occupied by *Salvia splendens*, with a background of berried Hollies and Willow-leaved Pear. The plants were raised from seeds sown in April and grown on steadily and planted in their present position at the middle of June. The display of colour during these autumn days shows the great value of this *Salvia* for the outdoor garden.

4 inches across, and emitting a delightful perfume towards the close of the day. This fine dwarf Evening Primrose should be in every garden, however small, for there is no more effective and valuable hardy plant grown. It is also well suited for the alpine garden.

FUCHSIAS, both hardy and tender, are beautiful now, and appear to enjoy the moist conditions prevailing, producing in abundance their graceful drooping sprays of flowers in various colours. These look happier now than at any period of the year, with one exception, and that is *F. fulgens*, which has suddenly ceased to bloom. The

SHAMROCK PEA (*Parochetus communis*), far too rarely seen, is now flowering more freely than has hitherto been the case this year. I have observed this in former seasons, the flowers being produced in greater profusion as the season advances, and so continuing until a severe frost lays it low. The small blue, Pea-shaped flowers surmounting the trailing, clover-like foliage are always admired. Unfortunately slugs are very fond of this plant, and a little protection is necessary for a

also propagated from cuttings inserted during late summer. Generally it is hardy here. The Japanese Windflower, in its many varieties, has been flowering profusely for a long time, and is still attractive, especially the fine pink variety, Queen Charlotte. The Starworts, which have been so much improved of late, are always a feature at this season of the year. Planted thinly among autumn-tinted shrubs, their beauty is much enhanced, while their value as cut flowers can scarcely be over-estimated. Everlasting Peas are still quite gay and valuable for cutting. Cactus Dahlias have been splendid and are still covered with flowers. The outdoor Chrysanthemums are making a gorgeous display and give promise of a long succession of bloom.

CYPERUS LONGUS and *Phragmitis communis* by the waterside are still bearing their attractive and uncommon flower-spikes. The Pampas Grasses, of which the Sunningdale variety, *Gynerium Rendatleri*, *G. argenteum pumilum*, and the true *G. argenteum* are a few of the best, are flowering freely. In irregular groups among old Vine-clad Apple trees, they are very attractive. Astonishing, too, is the way they have withstood the storms—especially the first, which is a magnificent variety. There is a vast difference in the beauty of these stately plants when grouped. The Sunflower family is valuable. Rising from among autumn-tinted Azaleas or thinly-disposed near groups of Starworts they have a pretty autumn effect. Heliotropes are still flowering freely on a sheltered border, but their perfume is not so apparent as earlier in the season. There are also many kinds of annuals the flowers of which, with a glimpse of sunshine, open as in summer. Especially beautiful are the Pimpernels, Swan River Daisy, Violet Cress, Snapdragon, etc., while *Tropaeolum tuberosum*, with its curious orange-scarlet, trumpet-like flowers, is at the height of its beauty.

Many shrubs and climbers could also be mentioned which are extremely beautiful, and help to increase the interest of outside gardening during these late autumn days.

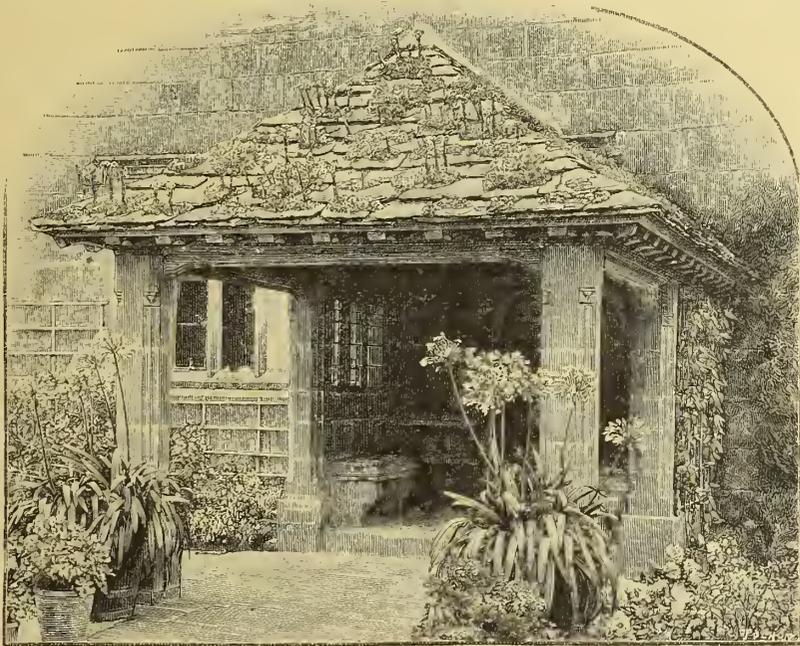

E. MARKHAM.

Sussex.

TUFTED PANSIES: EARLY PROPAGATION.

With much experience to the contrary I cannot allow the recommendations of "Woodview" (p. 639) to go unchallenged. One passage in the note referred to in particular calls for remark. It runs thus: "I find the greatest success has attended the propagation of these plants quite late in the year, and cuttings inserted in late October and throughout November have invariably rooted freely." I do not doubt it, but the right sort of cuttings would have rooted more freely, certainly much more quickly, had the cuttings been inserted two months earlier. Is not "quite late in the year" a contradiction of "early propagation"? Can "Woodview" aver that a cutting of Tufted Pansy has more vitality in "late October and throughout November"—that vitality and youthful energy which, in conjunction with favourable conditions, are so largely responsible for a quick and successful rooting—than it would have earlier in the season? I think not, and if not then his recommendation is faulty and his "greatest success" must be relegated to second or even third place.

Rightly treated, few hardy subjects are so useful as the Tufted Pansy. Perfect soil carpeters, simple cultural needs, early, free, and continuous flowering are some of the good points, but method and intelligence are required to bring them into being

Garden porch, roof covered with Houseleeks.

Plants that apparently enjoy the autumn days are the Cardinal Lobelias. So intense is the colour of these handsome plants when seen in good-sized groups that one is attracted by them from a considerable distance. These revel in plenty of moisture during the growing season, and the spikes of crimson flowers are produced with the greatest profusion, especially so in the variety Firefly, which I consider the best. Its more branching habit of growth and greater production of crowns facilitate its extended use.

GAZANIA SPLENDENS is as gay as in summer, its large, single, deep-yellow, Marigold-like flowers quickly expanding on the approach of an hour's sunshine. These Treasure flowers, with their large and attractive dark centres, are occasionally referred to as being coarse, but used with care they are very beautiful in the autumn garden. Easily propagated from cuttings put into boxes during late summer, and placed in a frame kept close for a time, after which it is only necessary to keep the frost from them, *Oenothera macrocarpa* is well furnished with its large yellow blossoms, each

time after planting, unless used in large vases, where it forms a most graceful draping. It is also very pretty falling over a low retaining wall. Cuttings inserted in sandy soil and kept close for a time root readily. *Felicia abyssinica* and *Bellis cœrulescens* are two charming little plants with pale mauve, Daisy-like flowers, which have never ceased blooming since spring. Both are still very pretty and ideal subjects for alpine gardens. The self-sown seeds of the *Bellis* germinate freely and scores of seedlings are available.

THE BLUE BINDWEED (*Convolvulus mauritanicus*), of which there is an excellent illustration in GARDENING ILLUSTRATED, October 23rd (p. 639), has been flowering unceasingly the whole summer and autumn; even now, with a little sunshine, it is bespangled with its fascinating lavender-blue flowers. As an edging it is delightful, while falling over the ledge of low walls it leaves nothing to be desired. In this position, and given a favourable season, it ripens seed freely, which, if sown during the following spring, forms nice little plants for summer use. It is

Too frequently the great value of early flowering of which these plants are capable is either overlooked or unknown, and "Woodview," who apparently, with many others, has not appreciated its importance in the garden, places—all unwittingly it may be—a stumbling-block in the way of progress by advising propagation in October and November. For many years, in order to obtain the earliest possible flowering from these plants, I made it a practice to plant my specimen beds during the first week of October, before, indeed, "Woodview" would have put in a single cutting. At that time the plants were sturdy little bushes of several shoots each, and were made possible in the following manner:—

With the greater flush of summer flower beauty past, the plants, so many as were required, were cut close back, the earth loosened about them, a mulch of rich soil given, finer material being sprinkled into the centre of each plant. From that time, failing rain, the plants were watered frequently, the result being that within a month the centre of each was bristling with new life. Then, as a direct result of the combined watering and mulching, these new growths rooted freely, so that at the end of a month or so it was possible to remove them by a sharp upward pull as rooted examples ready for transplanting. By taking the larger shoots first, room was afforded the remainder, and by repetition a maximum production was obtained. Thus, without the making of a single cutting and at a minimum of cost I have raised many thousands of plants and of a type—every one being of basal growth—that cannot be surpassed. The value of these basal shoots lies in the fact that they have latent eyes or buds, which, presently springing into being, give rise to the tufted character for which these Pansies are renowned. The system is good and sound for all, from the grower of thousands to the amateur for whom a few dozens are ample.

Transplanted to a bed of sandy soil these young plants soon pushed away into growth, when they were pinched to induce them to break, which they did freely. In this way by planting time in early October sturdy tufts resulted, and before the end of the year these same plants were bristling with shoots over a 6-inch area, their progress often a matter for surprise. I have rooted many thousands of ordinarily-made cuttings, and while possessing the advantages of the knowledge of both systems, am bound to say that for good results as well as labour saving that I have endeavoured to describe is by far the better. What is of infinite importance to the gardener is the early flowering of these October-planted examples, and by March—even occasionally while snow remained—I have had them bristling with buds and preparing to flower. This, indeed, is one of the greatest advantages of early propagation and planting, though with it should be deservedly associated the hold such plants get of the soil and which causes them to endure in times of drought. Those who still are content with the old system of cuttings and late autumn propagation, or, worse still, are satisfied with the results which divided examples afford, have yet to see these Tufted Pansies at their best, either as carpeters or when, for weeks or months on end, they are covered with flowers.

E. H. JENKINS.

NOTES AND REPLIES.

A smother fire.—Will you be good enough to tell me how to make a smother fire to burn garden refuse and which will burn slowly for days without causing a great amount of smoke and flame?—R. H.

[The first thing to be done is to estab-

lish a good body of fire with the aid of old Pea-sticks, branches and dead wood blown from trees during windy weather, or, failing this, faggot wood. If you have any old tree-stumps with roots attached, place these in the centre and build the fire around them. When the fire has been well started, and a good body of fire obtained, cover it over with the roughest of the material, such as Cabbage stumps, prunings, and the like. Put on a good thick layer of this, and then cover the whole mass with the finer material, such as weeds, vegetable refuse, sweepings, etc. If you have any soil infested with spores of any kind of fungus, such as may have been used for Tomato-growing, for instance, or which contains eel-worms or other noxious insects, this will afford you an opportunity for sterilising the same, as by casting it over the heap both fungus spores and insects will in due course be destroyed. After the fire-heap or smother has once been fairly set going care must be taken to see that it does not burn through, and keep a heap of the finer particles ready to hand to cast over any part where this is likely to occur, and before there is an outburst of flame. Unless the outer covering of the heap is very wet and heavy no draught-hole should be required. If, however, such is necessary it should be opened on the side from which the wind at the time may be blowing. With the necessary quantity of refuse at hand to feed the fire with, and by keeping the flames under control in the manner described, such a fire can be kept going for weeks, and without giving off a great deal of smoke. It would require looking to first thing in the morning, again about the middle of the day, and to be well banked up or smothered over at dusk, as such fires always burn with greater fierceness and rapidity during the hours of darkness. It would be well to ascertain first if the order with regard to the obscuring of lights is in force in your locality before starting a fire of this description, as it would be impossible to guarantee its not burning through at night, however careful you may be. If such did happen you would, unless you make sure beforehand, get into trouble.]

Protecting Tree or Moutan Pæonies.

While one would not advocate coddling such noble plants as the Tree or Moutan Pæonies, there are many places where the full measure of their beauty is not attained without some protection. It is in spring when the plants are growing, and have formed, or are forming, their buds, that the crisis comes. Then, too frequently, a sudden frost comes, and the hopes of a season are blighted, the buds destroyed, and the foliage badly injured. In places subject to such calamities precautions are necessary, and these often take the form of mats supported round and over the plants. Sometimes these are left on too long and the leaves and buds are rendered too tender, and suffer from less frost than should harm them. Branches of Laurels or Spruce set in the ground round the plants, and allowing of light and air, yet checking cold winds, are very beneficial, and save the plants from injury.—Ess.

Tropæolum tuberosum.—A recent note on this plant reminds one of the question as to whether there are several stocks, some more free flowering than others. At one time I was inclined to doubt if there were several stocks, some free flowering and others not. I have come to the conclusion that *T. tuberosum* does vary, and that it is necessary to secure tubers of a good flowering stock. I have known gardens in which this plant has been culti-

vated for several years without its flowering at all satisfactorily. In some years it did a little better than in others, but in other seasons it failed to flower at all. A stock secured from a garden where it flowered annually and freely gave splendid results. In the course of some correspondence regarding this point I received a letter from a correspondent who had been cultivating tubers for sale, and who had found it desirable to select bulbs from those which flowered most satisfactorily. This proved that the question of non-flowering is not one of soil or climate.—S. ARNOTT.

The Winter Heliotrope. (*Petasites fragrans*).—In the interesting lists of plants in bloom at this time, given weekly by "E. M.," mention is made of the Winter Heliotrope. I think that both this name and its newer title of *Petasites fragrans* are apt to be misleading to those who may not be acquainted with the plant. The older name of *Tussilago fragrans* would probably convey an idea of its general undesirability to many. In wild gardening it may have some value, but let the plant be introduced into the garden, and in the course of a few years the question will be how to get rid of it. The Winter Heliotrope is as difficult to eradicate as it is easy to establish—rivalling in this respect the *Convolvulus* or Bishop-weed. Apart from the period at which it blooms, and the odour of its flowers, which, to some extent, resembles that of Heliotrope, it is of little value. Its foliage is not ornamental, and the flowers are dingy and insignificant.—W. McG.

Polygonum vacinifolium.—Your note regarding the propagation of *Polygonum vacinifolium* by layers, on page 718, will be useful to many, as I know a number of people who have been unsuccessful in propagation by cuttings. It is perhaps the most attractive of all the dwarf *Polygonums*. It greatly dislikes being planted in a draughty place, and some people find it difficult to establish. It evidently likes a rather moist, cool position.—S. ARNOTT.

Sundials.—It does not follow that because the sundial has been superseded in popular economics it is therefore useless. We can remember one striking occasion on which a household found itself in considerable difficulties. The clocks, for one reason or another, were out of action, being cleaned or repaired or not having been wound up, and the family of four was dependent on its watches, or rather on three of its watches, for the fourth was disabled like the clocks. For some extraordinary reason all three watches chose the same day for breaking something in their insides. The family agreed that it must be something in the weather; but, whatever it was, there were several people with a very vague notion of what was o'clock. There were old silver watches that could be dug out and set going, but that did not meet the case until they could be given a fair start, and a solemn expedition had to be made in search of the time. Of course there was no sundial in the garden. If there had been, and some sun, the family, with "Whitaker's Almanack" in its hands, could have settled its present place in time as near as need be. For though there is some divergence between clock time and sun time, it is never very great (about sixteen minutes is the greatest discrepancy in the whole year); on four days clock time and sun time agree, and "Whitaker's Almanack," and doubtless other almanacks, enable a dial-reader to adjust his reading to the accepted standard in a moment. It is obvious that this might be of considerable importance to people living miles from anywhere who have occasional trains to catch.—Field.

VEGETABLES.

HOT-BEDS.

ADVANTAGE will be taken of the next spell of hard weather to get a good-sized hot-bed made up. This will be sufficiently large to hold four two-light frames. The bed will, therefore, be built both long enough and wide enough to leave a margin all round some 3 feet in width, both for the purpose of walking upon and to allow of linings being built round the frames when the heat of the bed declines. The bed will be constructed in a sheltered position open to the south, so that the most can be made of solar heat. The materials will consist of three parts freshly-fallen tree leaves and the remaining part of stable manure. Time and labour will not permit of all being mixed intimately and turned beforehand, as usual. It is not anticipated that this will prove any serious drawback, as the leaves are moist, therefore fermentation will speedily take place. To ensure the heat of the bed being lasting, and as a good supply of material is at command, it will be made about 5 feet in depth. Firm treading of the materials as the making of the bed proceeds is essential. To prevent inequalities on the surface as far as possible as the mass subsides, the leaves and manure will be evenly spread or placed in equal thicknesses all over the bed in the making. The corners and the outside of the bed will be of stable litter alone, which enables the bed being built more firmly and with substantial sides and ends, besides preventing the escape of heat. The whole is left to heat up before the frames are placed in position; in fact the surface is levelled and well trodden beforehand and bricks laid flat to carry the weight at all four corners of each frame. As opportunities offer, suitable compost for placing therein will be prepared. G. P. K.

THE PROTECTION OF CELERY.

It would be both instructive and interesting if cultivators would give their experience as to what extent protection to Celery is needed, or if at all. According to my experience the decay of Celery is more often than not due to other sources than frost. During a severe or prolonged frost a little protection is of great assistance, but the continual covering and uncovering of the rows which some people subject their Celery to cannot but be positively injurious. It is very annoying after trouble has been taken to have good Celery to find that at mid-winter the greater part has decayed. There is no doubt that the form of earthing which is adopted has much to do with early decay. By earthing too early the blanching is done much too soon; consequently, after a time decay commences, let protection from frost be ever so efficient. I have noticed in Celery that is over-protected that fermentation sets in through want of air and close confinement. Celery, however, to keep well must be well moulded up. A careful workman will see that this is efficiently done, the sides well sloped up and made fairly smooth, the soil being also well worked around the tops of each plant, which should, when earthing is finished, be exposed about 6 inches. Heavy coverings of litter or Bracken laid along the tops of the rows cannot but have an injurious effect, and late Celery will be in a worse condition at the turn of the day than even if left freely exposed. The best plan, if the weather should become unduly severe and there is no covering of snow, is to lay some dry litter or Bracken Fern along the sides of the rows and then

to shake a little of the very lightest and driest loosely along the top. If a heavy covering be put on and snow were to follow directly afterwards it would lie very close, and afterwards when a thaw set in it would become a wet and sodden mass, and the Celery would suffer accordingly. Damp is the worst enemy to Celery.

Whatever form of protection is used it must be so arranged that both light and air can have free access. Covering over with a cap by having two boards nailed together thus Δ has been frequently recommended. This season, if occasion should arise, I shall use a covering which builders place along the tops of walls for keeping out wet and frost. Instead of being of wood it is made of corrugated zinc. This being fixed so that the tops of the Celery are not bent over, there is no danger of either light or air being excluded. In time of severe frost with a covering of litter along the sides so as to facilitate digging up and a little laid over the opening I do not think there will be any fear of injury either from frost or damp. Celery that has been forced into a coarse growth by heavy applications of liquid manure and the too free use of artificial fertilisers will be the first to succumb. A.

Asparagus beds.—I should be glad of advice about my Asparagus beds. About how thickly should the stalks be allowed to run up, and should these be the strongest and earliest? After leaving a certain number, a mass of very small wiry ones came up all over the bed, making growth very thick, and weeding impossible. Should the berries be allowed to drop into the ground? On digging up an old bed, I found it to be a thick tangle of roots, and have made a new one. Do you think that the second old bed, probably in the same condition, should be replaced also?—F. M. G.

[The general rule after cutting ceases is to allow all growths which push up to develop. Previous to this all should be cut both large and small. What we suspect to be the matter with your beds is that a quantity of young crowns is overlying the original or legitimate occupants of the beds, this condition arising from neglecting to cut the tops away in autumn before the berries are dead-ripe. If the latter are allowed to drop on the beds countless seedlings appear in due course, and if left undisturbed the surface naturally becomes in time closely beset with thin wiry growths, which, owing to want of light and air, impede the development of the shoots that push up from the older crowns beneath them. Seedlings should, therefore, be ruthlessly suppressed, but if the precaution is taken not to let the seed fall to the ground none will then appear, while the weeding of the surface of the bed can be conveniently effected. As these seedlings are no doubt in complete possession of the bed in question, we advise you to form another new one with the intention of destroying the former as soon as the latter is ready for cutting from, which is in from two to three seasons after planting, or according to the age of the crowns employed for the purpose.]

Parsnips may be dug up now and the ground got ready for the early Cabbages or Cauliflowers. The roots must be kept from air or they will soon become tough. When a supply is required up to April the best way is to store a sufficient quantity in the ground, where they will keep fresh until then.

Two good Cabbage Lettuces.—About the middle of October, when looking over a trial of vegetables made with a view as to their value for July sowing, I was impressed with Ideal and Supreme Lettuces. These with others were sown at the end of July in the open. For autumn use they stood out above all others for their compact, hard, solid heads, the leaves of a pale green colour with a slight tinge of red on the tips. Supreme is the larger.—J. C. F. C.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM DECEMBER 16TH.—*Strawberry-tree*, *Jasminum nudiflorum*, *Laurustinus* (various), *Honeysuckle*, *Daphne Mezereum*, *D. Dauphini*, *Andromeda floribunda*, *Ivies*, *Erica alpina*, *E. mediterranea hybrida*, *E. carnea alba* and new hybrids, the *Cornish Heath*, *New Zealand Veronicas*, *Osmanthus ilicifolius*, *Polyanthus*, *Helleborus niger*, and *Winter Heliotrope*.

WORK OF THE WEEK.—A quantity of the Pasque-flower (*Anemone Pulsatilla*) having come to hand during the week a position was selected where the plants will be shaded by large Hollies for part of the day. The soil was not specially prepared as it was desired to grow the plants as hard as possible in order to compare them with those growing on rich ground, where we usually get from 50 blooms to 80 blooms on a single plant. A number of *Gentiana acaulis* has been lifted from the front of dwarf Rose beds, to which the plants formed an edging, and planted between the stones of a low retaining wall, a few being put at the top with a flat stone over their roots to keep them cool during dry spells. I find this way of growing this *Gentian* very satisfactory. A group of the Californian Poppy (*Romneya Coulteri*) has been planted, and a small heap of leaves or ashes will be put round the base of each plant as a protection from severe frosts. Several varieties of Torch Lilies have been put out near a large collection of established kinds, the large varieties being planted 2 feet apart and the small-growing ones at a less distance. These, for safety, should receive a little protection during severe weather, otherwise they are liable to get killed, especially if newly planted. A border about 15 yards long has been edged with *Epimedium sulphureum*. The plants had become very large, having occupied the same position for a number of years. They were parted up into medium-sized pieces and planted a foot apart. This fine edging plant requires plenty of space, as on strong soil it will grow from 18 inches to 2 feet in height. The leaves in winter turn a lovely bronze colour, and are useful for decoration indoors. The old leaves should be cut off the plants towards the end of March, otherwise the blooms, which commence to appear very early, will suffer, whereas if taken off before the flower-spikes develop all risk is avoided, the satiny-like leaves and yellow blossoms appearing together. A further batch of *Blue-eyed Mary* (*Omphalodes verna*) has been planted in the Grass bordering some steps, where it is expected to naturalise, as it has done in various other parts of the garden. Clearing by the waterside has been carried on during bad weather, and a large plantation of Red Willows, which are grown for tying, has been partly cut. These are sorted on wet days and tied into bundles of different sizes. E. M.

Sussex.

SOUTHERN COUNTIES.

Cyclamens.—These will soon be in full bloom. Their requirements can be met in a far more satisfactory way when they have a house given up entirely to them. A house of *Cyclamen* in full bloom always, by reason of there being such a wide range of colours among the flowers, commands admiration, and they are then far more effective than when stood amongst other flowering plants. Each plant now requires sufficient space so that it stands just clear of its neighbour, as crowding leads to attenuated leaf-stalks and flower-stems. As the individual flowers fade, the stem

should be pulled clean out with a jerk and not cut off, otherwise the portion of stem left will rot and cause mischief among the buds on the crown of the corm. Another reason for ridding the plants of the flower-stem directly the flowers fall is to prevent seed-bearing and its exhausting effects. When gathering the flowers the stems should always be pulled clean out from the base and not cut. Care now has to be exercised when watering not to pour water over the crowns of the corms, otherwise decay among the flower-buds will set in.

Calanthes. — To prolong the blooming period these have been placed in a house where a mean temperature of 55 degs. is maintained, and arranged among other plants in such a manner that the pots are partially hidden from view. The flower-spikes in all cases are satisfactory, and when fully developed will be quite up to the standard as regards length and in being well furnished with flowers. The hybrid variety, *Bella*, is now producing its robust racemes, which will form a good succession to *C. Veitchi* and *C. vestita* and its varieties later on.

Carnations. — The young stock raised from layers last autumn has now been shifted into 5-inch pots. The usual rule has been to let them remain in the pots into which they are put when lifted from the layering-frame, transferring them to 7-inch pots in January. To have done so on this occasion would have led to their becoming pot-bound, and, consequently, ruined before the final potting could have taken place. This double shifting has entailed a greater expenditure of labour, but the plants will benefit by it and eventually yield larger blooms. Some dozen different varieties are grown, but care is taken to see that there is a preponderance of that fine old variety *Princess of Wales*, as it is undoubtedly still one of if not the best. The plants have been arranged on an open stage overlying another stage covered with coke broken small, which, on account of its absorbent nature, keeps the atmosphere about the pots cool and to a certain extent moist also, which tends to prevent the soil in the pots from drying out too quickly. Until roots begin to work into the fresh compost watering has to be done with the greatest care. The house is kept quite cool, frost alone excluded, and abundance of air admitted on every favourable occasion. Two-year-old plants have made very satisfactory progress and are now ready for staking out. Slender Bamboo stakes are employed for this purpose, from five to six being used for each plant according to the necessities of the case.

Border Carnations. — It has been deemed necessary, owing to the abnormally wet weather of the past few weeks, to remove the plants from the cold pit in which they were placed when first potted to drier and more airy quarters in case leaf spot should set in. This step is of a temporary nature only, as the plants will be returned again to the cold pit as soon as more favourable weather prevails.

Herbaceous Calceolarias. — The most forward plants are ready for their final shift into 7-inch and 8-inch pots. In this size of pots the plants, with careful treatment, will make handsome specimens which, when in flower, come in useful in the early spring months. The compost used consists of two-thirds fibrous loam pulled to pieces by hand, one-third flaky leaf-mould, a small quantity of dried cow-dung and fine mortar rubble, a little soot, and a liberal quantity of coarse silver sand. Clean, well-drained pots are very essential, and the compost should be made moderately firm only. The repotting of

the successional batch as well as a number of plants of *C. Clibrani* will be deferred till after the turn of the year. The house in which all are accommodated is kept cool and moist, and aired according to outer climatic conditions both at the top and front. The watering of this class of *Calceolaria* has to be done with care, as an excess of or the withholding of moisture, when necessary, is fatal to success.

Early Peaches. — The early house may now be closed, but unless severe or cold weather should set in no fireheat is required for the first two or three weeks, as the temperature may fall as low as 40 degs. without giving the slightest occasion for alarm. Although heat is, with the foregoing reservations, unnecessary at starting, the raising of the temperature of the border with a good soaking of tepid water is imperative, and this and the closing of the house should be done simultaneously. Beyond damping the pathways nothing further in this direction is needed until the period mentioned above has expired, when with a slight heating of the hot-water pipes at night and by day also when requisite to ensure a temperature of 50 degs. to 55 degs. syringing of the trees may be commenced, *i.e.*, when the weather is fine and bright, but limiting the supply of atmospheric moisture to damping alone when it is dull. Air may be admitted when solar heat runs the mercury up to 65 degs., but it should be reduced and finally shut off as soon as a fall in the temperature begins to take place. As there is always an uncertainty about "fly" putting in an appearance on forced Peach-trees when in bloom if fumigation is neglected, it is always wise to vaporise both when the house is closed and before the trees come into flower. If properly carried out this will carry them safely over the flowering period.

Pot Vines. — With everything in readiness these can now be started with a day and night temperature of 50 degs. and 45 degs. respectively for the first fortnight, after which a rise of 5 degs. may be allowed. The canes, with their points brought down on a level with the pots to ensure a more even break of buds, need syringing with tepid water once a day in dull, and twice in bright, weather. To promote the requisite degree of humidity the paths, etc., need damping, when the weather is bright, daily, especially in the morning and when finally closing for the day. The soil about the roots requires to be well moistened at the outset with tepid water, but afterwards it must be applied only when it is required, which can only be ascertained either by actual examination of the soil or by the more practical method of rapping the sides of the pots.

Early Vinery. — This will now be cleaned and put in order ready for starting early in the New Year. The Vines, having been pruned some time since, they merely require to be relieved of loose bark, scrubbed, and dressed with sulphur made into a thin paste with the aid of hot water and soft soap after the house has been cleaned down. This is best applied with a sash-tool and should be well worked into the bark and round the spurs. Until the buds break, the rods are loosely suspended from the trellis with the points hanging downwards to equalise the flow of sap. The border having been added to last year, only a top-dressing is now required. The border, being, if anything, on the dry side, will be moistened throughout with tepid water, which will also serve to wash in the artificial Vine manure sprinkled on the surface before spreading the top-dressing material thereon. Economy being the order of the day, fireheat will not

be resorted to for the first two or three weeks after closing the house, sun-heat alone being relied on to induce the buds to commence swelling. During this period the ventilators will remain closed to husband sun-heat as much as possible. When bright, damping of the floor and border surface will provide a sufficiency of moisture until the swelling buds demand more warmth, when both damping and syringing also must be done to counteract the dry heat arising from the use of the hot-water pipes which becomes necessary when this stage is reached. The temperatures then will be 50 degs. by night and 55 degs. by day. A. W.

MIDLAND COUNTIES.

Melons. — Seeds for an early crop will now be sown in 2½-inch pots filled with fine moist loam lightly mixed with leaf-soil. The pots are placed in a house having a night temperature of 65 degs. to 70 degs., and when the soil has become thoroughly warmed one seed will be placed in each. Plunge in a warm bed and cover with glass. Do not water until the seedlings appear. They should then be replunged in a shallow box filled with Moss or similar material, and put on a shelf near the glass. By careful attention to watering, daily syringing, etc., the plants will grow away freely. Although the earliest Melons can be successfully grown in pots, I find that the plants cultivated in beds are the more satisfactory. The earliest crop needs a hotbed, and the material for forming this should be prepared at once, using partially decomposed leaves and stable litter in equal parts. I have hot-water pipes under the fermenting materials, and it is, therefore, only necessary to have a small hotbed, the top of which is raised to within 15 inches of the trellis. On this hotbed is placed a bed of soil 18 inches wide by 9 inches deep. The soil is made quite firm. If the loam is of a retentive nature, the inclusion of some old mortar rubble will improve it, and poor soil may be enriched by the addition of bone-meal.

Cucumbers. — Young plants will now be raised to fruit in succession to the old plants now showing signs of exhaustion. The seeds are sown singly in 2½-inch pots containing a compost of loam and leaf-mould in equal parts. The soil should be warm when used, and sufficiently moist so that no water will be required until the seeds have germinated. Plunge the pots in a similar hotbed as advised for Melons. A hotbed will afterwards be required, as in the case of Melons, for forming the beds upon. An atmospheric temperature at night of 65 degs. to 70 degs., and an increase of about 10 degs. during the day will be suitable for Melons and Cucumbers.

Bouvardias. — As these go out of flower they should be removed to a cool-house, and watered sparingly. Plants which were rooted in spring, and are flowering now for the first time, may be expected to continue in bloom. Those which have already been cut back two or three times usually flower for a shorter period.

Hydrangea hortensis. — Plants which were rooted during the summer and autumn and are growing in 4½-inch pots need to be examined. Those showing the flower-buds may be placed in a warmer house, where they will bloom early in the season. Hydrangeas last for a long period in bloom, and the flowers are varied in colour.

Liliums. — A consignment of *Lilium auratum*, *L. longiflorum giganteum*, and *L. speciosum magnificum* has just come to hand, and will be potted up immediately. Pots to suit the size of the bulbs are used. The compost for *L. auratum* will consist

of equal parts of good fibrous loam and peat with the addition of a little leaf-soil and coarse sand; for *L. longiflorum*, three parts good fibrous loam, one part leaf-soil, a little manure from a spent Mushroom bed, and coarse sand; and for *L. speciosum* three parts good fibrous loam, one part peat, one part leaf-soil, and some coarse sand. A little sand is placed under the bulb, which is kept well down in the pot, placing a moderate layer of soil over it, leaving room in the pots for adding a top-dressing when the growth is well advanced, but before the roots have begun to develop from the stem. The stem roots are of great value to the bulb, and should be carefully looked after. After the bulbs are potted they are placed in a frame and plunged in a bed of leaf-soil, so that the pot is just out of sight and kept secure from frost. They are allowed to remain in this position until growth has commenced. *L. longiflorum formosanum*,

discretion. Well screened coal ashes are valuable for sprinkling among herbaceous and alpine plants. The planting having been arranged for the coming season, it is known approximately what number of the various plants will be required. The propagation of particular plants required in great numbers will be commenced forthwith. Rooted cuttings will shortly be removed from the boxes in which they were struck and potted up singly into 3-inch pots. All plants that were rooted in the autumn and intended to be trained as standards are kept growing steadily, and when necessary afforded larger pots, but care is needed not to overpot them, and watering must be done with care.

Violets planted in frames need great care at this season. All decaying leaves must be removed, and the soil stirred occasionally, especially if it has a tendency to become caked. Air must be admitted whenever possible, as Violets never suc-

any of the Brassica family be allowed to occupy the same ground two years in succession. Onions may be grown on the same plot of ground from year to year without any ill-effects, provided the ground is well prepared each year. Jerusalem Artichokes and Horse-radish will also do quite well on the same spot for a number of years, provided the ground is trenched and plenty of farmyard manure worked in. The

Selection of varieties of vegetables from the seed-list should be given very careful attention. Varieties that succeed in one locality may be, and often are, a complete failure in another district. The best of everything should be grown, as inferior sorts require just as much, if not more, attention as do the superior varieties. Good standard kinds should always be grown for the maincrop, but a few of the new kinds may be included, as they afford opportunities for comparison with the

A well-grown Cineraria.

potted early in October, has made good progress, and has been top-dressed. The plants are growing in a temperature of 60 degs. to 65 degs., and I expect the first batch in flower at the end of February.

General work.—Cleaning shrubberies and clearing away worn-out shrubs can be done in almost any weather. The ground should be thoroughly cleared of all roots, especially those of Nettles, Woodbine, and others which accumulate in neglected shrubberies. Any shrubs which require a severe pruning should be left until the spring, as there is danger of killing even the hardier species if they be cut hard back during winter. At this season close attention is necessary if good displays are to be realised in spring. Maintain a close observation upon the least robust of the spring-flowering plants. For affording a slight protection from frost, branches cut from Yew-trees are very convenient, but they should be employed with

cead in a close atmosphere. If water is needed it should be applied on mild, open days, for then extra ventilation can be given without fear of injury to the plants.

Kitchen garden.—With the New Year the work in this department must be proceeded with in earnest if the best results are to be obtained. A rough plan of the vegetable garden should be made, marking on it where each of the principal crops is to be grown. The preparation of the ground is of the utmost importance, more depending on this than many people imagine. I am a strong advocate of deep trenching, and each year I am more fully convinced as to its value. What are termed old and worn-out gardens can be improved, and new life imparted to the soil by bringing up the bottom to the surface and working in suitable ingredients.

Rotation of crops.—Except in a few instances, it is necessary to change the site of crops each year. On no account should

older ones, and whether they prove superior or not they are interesting.

F. W. GALLOP.

SCOTLAND.

Shrubberies.—Birds have worked considerable havoc among the various berry-bearing shrubs, Hollies having suffered severely, some of them, in fact, being quite cleared. Cotoneaster frigida has also paid toll, although in this case there has not been quite such a wholesale clearance, some of the pieces yet remaining highly effective. Stray pieces of the common Barberry still retain their foliage, this having assumed a beautiful ruddy tint, among which the berries are rather difficult to detect. This fact may account for their comparative immunity from the attacks of birds. Be that as it may, there are proportionately more berries upon these than upon other shrubs. *Leycesteria formosa*—relished by pheasants—has

berried fairly well, and, as yet, has not been interfered with. *Garrya elliptica* comes on apace. Lilacs are well set with buds, and now that the foliage of *Azaleas* has dropped it is possible to note that the promise of flower is exceptionally good. *Rhododendrons* of all kinds have grown well, and in their case, too, a good display may confidently be expected. *R. Noble-anum*, one of the earliest varieties, will apparently be later than usual. The withered plumes of *Spiraea arifolia* ought really to be removed, but being attractive they will, meantime, be permitted to remain. *Andromeda floribunda* is well covered with racemes which will expand before very long, and a rich promise is noted on *Hamamelis virginica*. *Skimmia japonica* and the Mexican Orange Flower (*Choisya ternata*), suited by their environment, continue to grow luxuriantly. Apart from its wealth of bloom during the flowering season, *Choisya ternata* is desirable on account of its dark green and glossy foliage. *Kalmias* are, at present, looking fairly well, and some colonies of *Bamboos* which were planted some years ago are now making shapely and attractive clumps. Here and there in sheltered places are to be found sprays of *Berberis Darwini* in bloom, and *Escallonia macrantha* is also bearing a few flowers.

Stove.—A useful plant is the variegated Screw Pine (*Pandanus Veitchi*), and young offsets taken at this time and placed in the propagating pit will soon root and form useful little plants. In the case of existing plants of some age, overpotting must be guarded against, for if too much root-run is given there is a danger that the variegation will not be clear; indeed, the leaves may turn entirely green. This plant is useful for rooms, and is valuable for that very reason during the winter months. The more tender Ferns are never, I think, more attractive than during winter in the stove. The delicate tints of the young fronds of *Adiantum Farleyense*, *A. Ghiesbrihti*, and *A. Henslovianum* do not suffer from the sun as they do, unless shaded, at a later date. Among other Ferns which thrive more satisfactorily in the stove during winter are certain of the *Davallias* and all the *Gymnogrammas*. In the absence of a regular forcing-house much use can be made of the stove, and bulbs and flowering plants intended for greenhouse and conservatory decoration can be rapidly brought forward in the desired numbers. For such a purpose, shelves are almost indispensable in order that the pots may be placed as near the light as possible. During the week a considerable number of well-rooted *Hydrangea* cuttings was taken from the propagating pit and put into 3-inch pots. The young plants were afterwards returned to the stove, in which they will be permitted to remain for a short time until the roots begin to move freely in the new soil, after which they will be placed in a cooler atmosphere. At the same time some promising young *Coleuses* were moved into 4-inch pots, with a view to maintaining growth until spring, when they will be grown on. *Fittonias* of sorts make useful furnishing plants, but they always appear to be very susceptible to damp in winter, and thrive better when grown in shallow pans than when pots are used. *F. argyoneura* and *F. Verschaffelti* are desirable varieties. The easily-propagated Indian Grass (*Panicum variegatum*) makes a good edging plant, as do some of the better *Tradescantias*. Watering must now be in careful hands. Syringing is, meantime, dropped, the necessary atmospheric moisture being maintained by damping the pathways occasionally.

Greenhouses.—The earlier *Chrysanthemums* are now on the wane, more, per-

haps, from the effects of damp than anything else. The late sunless spell has materially shortened the display, and although some heat has been maintained, it is dangerous to use too much, as, when *Chrysanthemums* are given more heat than they relish, the season is shortened quite as much as from damp. The late-flowering varieties will now be made use of—all bush plants. The ordinary run of winter-flowering stuff maintains variety and gives plenty of material for cutting. *Lygodium scandens*, *Medeola asparagoides*, and *Heliotrope* among climbing plants are useful. No attempt is, as yet, being made to hurry on bulbs, *Cinerarias* are being kept quite cool, and the flowers of the different *Primulas* are still being picked off as they appear.

Wall-trees.—In rather unfavourable weather some further progress was made with the pruning and training of wall-trees, a finish being made among Pears, while only a few Plums remain to be attended to. Upon certain portions of the walls there is a thick growth of such wall plants as *Linaria Cymbalaria*, *Erinus alpinus*, the Red Valerian (*Centranthus ruber*), and various species of Ferns. Where these are encroaching unduly some amount of thinning was done, but, on the whole, the presence of these plants does not seem to be prejudicial to the welfare of the fruit-trees. It might be inferred that *Linaria Cymbalaria* would, perhaps, be dangerous in respect of encouraging red spider, but such is not the case, observation extending over a considerable number of years proving that no evil effects result from the employment of this, and the other plants mentioned, in the interstices of the walls.

Hardy flower borders.—Cutting over of the ripened stems having now been completed, a steel rake was run through the borders to make them, meantime, as tidy as possible. Many of these borders are so full of bulbs that, at present, it would be dangerous to stir the soil, so that it will be delayed until their tips are visible. A little spent hotbed manure having become available, this and some half-decayed leaves will be utilised among the borders.

Parsley in frames.—The supply out of doors yet remains plentiful, but when, as has been the case upon two occasions lately, there is a heavy fall of snow, the value of Parsley in frames is apparent. On all suitable occasions a free allowance of ventilation is afforded, and water, unless when absolutely needful, is withheld. Any decaying leaves ought to be promptly removed, and should symptoms of damping be observed, a dusting of freshly-slaked lime will be found beneficial.

Vegetables continue to be fully adequate to the demand at present. The Cauliflower season was more prolonged than usual, the last heads of Autumn Giant from the open having been cut early in December. Jerusalem Artichokes are of good quality, Sprouts and Savoys will provide plenty of material for an extended period, while Leeks and Curly Greens yet maintain a certain amount of growth. Decayed or rotting leaves are removed as opportunity offers, and such things as Cabbages for spring use, Spinach Beet, and Winter Spinach are, from time to time, given a look over in order to prevent accidents as far as possible. In the course of the week roots in store were inspected, and Potatoes were picked over. These are, so far, keeping very well. Disease was practically non-existent, and, as a result, there has been little or no rotting among the stored tubers.

W. MCGUFFOG.

BOOKS.

"SUGARLESS JAM-MAKING AND FRUIT-BOTTLING."*

WITH a view to further war time economies Mrs. Helen Wyldon has brought out a little work entitled "Sugarless Jam-making and Fruit-bottling," price 1s. The advantages of this system are said to be that fewer jars are required, less than the ordinary shelving-room is necessary, the cost is less, and the process takes less time and fuel. A certain amount of sugar is actually used in making the preserves, saccharine is used for flavouring, and gelatine or isinglass to stiffen them. There are in the book five recipes only. In these days of cheap printing and other economies the book strikes one as dear. We would have preferred that in preserving her fruit the authoress had not introduced bladders from the butcher and used here and there other animal substances, as these do not appeal to real fruit-lovers.

ROYAL GARDENERS' ORPHAN FUND. SPECIAL APPEAL.

IN view of the serious crisis through which the nation is passing, and the need now more urgent than ever for taking care of the child life of our country, the Executive Committee of the Royal Gardeners' Orphan Fund ventures to plead most earnestly with all interested in horticultural pursuits for some financial help to enable it to carry on the work of the fund during this time of great stress. The fund was established in 1887 to aid in maintaining and starting in life the helpless and necessitous orphan children of gardeners. It is entirely supported by voluntary contributions, and has only an assured income from investments of about £400. It depends for its main source of revenue upon the collections made in connection with the annual festival dinner, which usually takes place in the month of May. Last year the income derived from this source amounted to £1,060 17s. 7d. This year, owing to the war, the committee has felt compelled to abandon the annual festival, with the result that the fund is faced with a heavy deficit.

In 1914 the sum disbursed in weekly allowances and grants in aid to candidates awaiting election amounted to £1,868 2s. 6d., and as there are now 136 beneficiaries (including 16 elected in February last) in receipt of full benefits, and 19 candidates waiting for election and receiving compassionate allowances in the meantime, no reduction in expenditure under this heading is possible or desirable, for the needs of the unfortunate children are as pressing as ever.

Since the fund was established over £30,000 has been expended in befriending children left behind by men of a worthy, but often poorly paid, calling, and in this practical way the burdens of many poor widows whose breadwinners have passed away all too soon to make any provision for them have been mercifully lightened.

The committee most earnestly appeals to past supporters to kindly continue their contributions, and to the many who have so far overlooked the claims of the fund to subscribe at least something towards carrying out the purpose of the institution.

The treasurer will gratefully acknowledge any contributions sent to 19, Bedford Chambers, Covent Garden, London, W.C.

* "Sugarless Jam-making and Fruit-bottling," by Helen Wyldon. London: Polsue, Ltd., Gough House, Gough-square, Fleet-street, E.C.

CORRESPONDENCE.

Questions.—*Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly written on one side of the paper only, and addressed to the EDITOR of GARDENING, 63, Lincoln's Inn Fields, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, the name and address being added to each. As GARDENING has to be sent to press some days in advance of date, queries cannot always be replied to in the issue immediately following their receipt. We do not reply to queries by post.*

Naming plants.—*All who wish their plants to be rightly named should send fair examples of each—the stem, leaf, flower, or fruit. (Snippets of leaves and points of shoots are useless.) Not more than four plants should be sent in any one week by the same correspondent. Where more than one kind is sent they should be numbered. Of conifers the fruit should always be sent.*

Naming fruit.—*Several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. We can undertake to name only four varieties at a time.*

PLANTS AND FLOWERS.

Sediment on leaves of greenhouse plants (P.).—We think, if you will examine the Orange-tree, you will find that it has been attacked by brown-scale, which is evidently spreading to the other plants in the house. The plants have also been attacked by green-fly, which has caused the sediment on the leaves. The best cure for green-fly is fumigating with one of the many remedies advertised in our pages. You must wash the Orange leaves carefully with some insecticide.

Growing Agapanthus (C. H. C.).—Being a liberal feeder, the soil into which it is potted may consist of two-thirds good turfy loam and one-third well-decayed manure, with a sprinkling of rough sand. It needs plenty of water during the growing period, and, when the pots are full of roots, a little liquid-manure at that season about once a fortnight is very beneficial. The leaves die off in the autumn, and the plant needs to be wintered where just clear of frost, but nothing more. Throughout the winter only sufficient water should be given to keep the soil slightly moist. With the return of spring and renewed growth more water must, of course, be supplied.

Keeping Fuchsias in winter (C. H. C.).—Fuchsias put away in winter often suffer through over-dryness and too much heat, and, as a consequence, if they survive until spring, are often found to be in a debilitated and weak condition. A warm temperature is not necessary for them during a period which ought to be one of comparative rest, and the practice of packing plants under a greenhouse stage at the back of heat-pipes, where they get over much moisture and excess of heat, is not to be commended. The best place for them is a cool-house or potting-shed from which frost is excluded, and this is all they actually want until February, when they may be brought into heat, cut back, and growth encouraged.

Potting Lillium (G. B.).—Pot at once. The size of the pot will depend on the size of the bulb, and for your bulb you will probably want a 10-inch pot. After you have potted the bulb stand in a cold-frame and cover with about 6 inches of Cocoanut-fibre. If the potting soil be in a fairly moist condition, no water will be required until the plant starts into growth. Remove the fibre from time to time to ascertain if the bulb has begun to throw up a flower-spike. As soon as this is seen to be the case the fibre above the pot should be cleared off, and the plant either left to grow on in the frame or be removed to a cool greenhouse. Introducing into heat before the bulb has showed signs of starting should never be practised; indeed, cold treatment best promotes a healthy and vigorous growth.

Dahlias, lifting (R. H.).—When the frost has destroyed the foliage, cut off the stems 9 inches from the ground, then, with a fork, lift the roots, taking care not to break any of the fleshy tubers. Shake out as much soil as you can from among the tubers or pick it out with the aid of a pointed stick. Then turn the roots bottom upwards, to allow any sap or liquid that may be in the hollow stems to run out, and when the roots are fairly dry place them in shallow boxes, close together, and cover them up with fine, dry soil or ashes, well

shaking it in among the tubers. Stand them in some place where the temperature does not fall below freezing point, and where it is fairly dry and not under drip. So treated, your roots should keep well through the winter.

Plants for cold-house (Reader).—It is now too late to do anything in the matter. You should have purchased, early in the autumn, bulbs of such as Hyacinths, Tulips, Narcissi, etc., which you should have potted up and stood in the open air, covering with ashes, and when well rooted transferred them to the house you speak of. Azaleas (hardy), Prunus, Deutzias, Rhododendrons, and such like should also have been potted up and kept in the open air till you wanted to get them into bloom.

Growing Nerines (N.).—Nerines should, when flowering is over, be placed in a light position in the greenhouse and kept watered. This is owing to the fact that new leaves are pushed up at about the same time as the flower-spikes and growth continues throughout the winter and into the spring. It is at that time that the bulb is built up for another season's growth and flowering, flowers being ensured by withholding water and exposing the bulbs to the sun. Then by August a watch must be kept, and directly there are any signs of growth the plants must be watered. As a rule, the flower-spikes are the first visible signs of growth. These will make rapid progress if the plants are kept in the greenhouse, in which they will form a brilliant autumn feature. When Nerines are thoroughly established in their pots an occasional dose of liquid-manure during the growing season will be beneficial.

The value of mulching (L.).—There is no doubt that in heavy, retentive ground, a winter mulching of rich manure adds to the coldness of the soil and is harmful rather than beneficial to Roses, and with the greater dampness comes the more severe effect of frost. In warmer soils the consequences of the mulch are not so disastrous and there is doubtless benefit derived from a light, littery mulch early in autumn, which should occasionally be forked up and not allowed to settle into a sodden mass, as this retains the warmth of the ground, and is effective in preventing the frosts from penetrating soil to any depth later on, provided it is kept loose and not allowed to solidify. It is in the spring, when the plants are starting into vigorous growth, that the value of a rich mulching comes in. In heavy soils the best method of protecting Rose bushes is to heap a little of the surrounding soil about their roots.

The Throat-wort (Trachelium coeruleum) (J. L.).—This is easily propagated in the spring from cuttings taken from the base close to the soil, some of these possibly having roots of their own. Such plants will flower the same season in 6-inch pots, being afterwards kept to grow on the following spring, so as to provide, if need be, a set of larger plants. Seedlings can also be easily raised, but when this plan is adopted the seed should be sowed and sown as soon as it is ripe from plants that have flowered early in August. The seedlings can then be kept in a box or pan in a cool greenhouse during the winter. It is not necessary to devote house room to it from the end of March until the flowering season comes round. This plant will do good service at a season when any novelty is a pleasing change. The best trusses of violet-blue flowers are produced on the terminals, but the lateral shoots on strong plants are also very effective. The best soil is loam and leaf-mould, with a little sand, potting being done very firmly.

TREES AND SHRUBS.

Pruning Pyrus japonica (D. C.).—This will always flower better when allowed to grow naturally than when closely pruned. Such being the case, it should only be cut back so far as is really necessary to keep it within bounds. Any old or exhausted shoots should be cut clean out, as by so doing the young, clean growths on which depends a good deal of the future display is encouraged. A good time for doing this is as soon as the flowering period is over, as then there is a long growing season before it. You may, if you do not wish the plant to grow too far away from the wall, shorten in the season's shoots, and thus induce the formation of spurs or flower-buds. This can be done, of course, immediately after flowering. Lay in the best of the young wood, and spur back any that is weak. Cut away the weakest of the growths that spring from the base, and nail in as many of the others as you have room for.

Crataegus Pyracantha not fruiting (W. H. B.).—The reason of your Pyracantha not fruiting is that it grows too freely, hence it must be served as many of its relatives the Apples and Pears are when they produce wood rather than flowers and fruit. You may try root-pruning by taking out a trench at 4 feet from the main stem, cutting off the roots as you proceed till the lowermost that extend outward are reached. Where the soil is heavy, 3 feet from the stem will be sufficient for the trench, but in lighter soils the roots generally extend for some distance, and these are but few. We should not be surprised if you find that one or two strong roots have followed the footing of the wall and travelled for some distance. The pruning of the top may be limited to the thinning out of any overcrowded branches in order to allow light and air to play amongst them. If your Pyra-

cantha is treated as above detailed, we think it will lead to an ample display of flowers and fruit.

FRUIT.

Pruning Peach-trees (M. B.).—It is very difficult to advise you, as you give us no idea as to the age of your trees and the treatment they have received during the past summer. Early in the spring, when the young shoots are starting into growth, the trees should be gone over, rubbing out all the shoots which spring from the front of the branches or those right at the back. Then a little later at least one-third of the other shoots should be pulled out, carefully preserving those at the base of each branch. These shoots must be laid in as close to the wall as possible, so that the wood may get thoroughly ripened. After all the fruits have been gathered, any bare branches or old wood should be cut back and the young growths reserved to take their places nailed or tied in. This is best done in the winter after the leaves have fallen. It is very difficult to convey instructions as to pruning in writing, and we should advise you to call in the aid of a practical man in your neighbourhood. We do not reply to queries by post.

VEGETABLES.

Cabbages, etc., clubbing (A. T.).—The best remedy for clubbing is undoubtedly gas-lime. This should be applied to vacant ground at once at the rate of 2 bushels to 3 rods. After lying on the ground for from four to six weeks dig the gas-lime in. Plant Potatoes, Seakale, or Rhubarb on the ground, or sow Onions, Parsnips, or any other vegetable, but not any of the Cabbage tribe. You must bear in mind that you cannot crop the ground so dressed for three months.

MISCELLANEOUS.

Worms in pots (S.).—We think the best way of dealing with the worms in the pots is to get some fresh lime and make a solution of lime-water—say, put a quart of lime to a gallon of water. Stir it well and let it stand for a few hours until the water is quite clear, then pour off into a water-pot and give to the pots in which the worms are. This should be repeated two or three times in the case of plants with a large ball of earth attached to the roots. The lime-water will cause the worms to come to the surface, when they may be picked up and destroyed.

Making a hotbed (F.).—In making a hotbed a much steadier heat is obtained by placing the manure in heaps, turning it over several times before placing it in the pit or bed. If placed direct it heats very rapidly, and quickly gets cold again. Thoroughly mix all the materials together, and turn when heated through, not allowing the manure to get very hot. Make the bed as firm as possible to retain the warmth, and as soon as the steam has evaporated, or after two or three turnings. Much depends upon the quality of the manure, and if strawy, freshly-gathered leaves should be mixed with the manure. The heat is then retained much longer.

SHORT REPLIES.

H. L. Kent.—Your best plan will be to get a copy of "Vines and Vine Culture," price 5s. 6d. post free, from Mrs. Barron, 13, Sutton Court-road, Chiswick, London, W.

NOTES OF THE WEEK.

Patrinia palmata.—I grow this in a moraine without limestone, and facing almost due south-east. It has thriven and increased, and flowers regularly. The sweet-scented flowers are small, and are redeemed from insignificance mainly by the number produced on the umbels.—S. ARNOTT.

Bagging Pears.—Are paper-bags better for Pears than those made of muslin? Birds cannot tear muslin. I used them last year and was pleased with the result. I made the bags of butter-muslin, and when the Pears were gathered the muslin-bags were washed, and are now waiting for the 1916 crop. Please say if paper-bags would be an improvement on my plan. Muslin admits sunshine, which I thought would improve the fruit. My Pears were never better than this year.—F. L. CLARK, *Yorks.*

Cardamine pratensis.—I enclose leaves of this plant, showing how new plants form at the base of the terminal leaflet. I was ignorant of this habit, and having cut off the flower-heads was surprised at its spreading. Now I see how rapidly it can mat suitable soil by the 5-inch steps of leaf from plant to plant. It gives evidence of its family resemblance to the bulbiferous Dentaria, and is a native exemplar of the habit which interests all who see it in Tolmiea Menziesii. Both plants revel in a damp or mossy situation.—H. R. B., *Attleborough, Norfolk.*

Lapagerias out-of-doors.—I think these plants are much more hardy than many think, provided they have their roots in suitable material. In S. Devon I have seen some fine plants as regards vigour and size of blossom growing on a church-wall facing east. Some growing on a porch 15 feet high were grand. These had a south-west aspect and had no shelter of any kind. The soil, of a peaty nature, was well drained, and I was informed the plants always flowered freely. The severe winter of 1895 killed the plants to the ground, but since then they have not suffered, a few of the young growths only being browned by late spring frosts. In Cornwall these plants are very beautiful in many parts.—M. C. R.

Lapageria rosea in Scotland.—It is well understood that Lapageria rosea is comparatively hardy in several districts, but it is not so generally known that there are a few Scottish gardens where it stands the winter well and flowers annually on a

wall. One of these is the garden of Mr. Wallace, of Lochryan, at Cairnryan, near Stranraer. At Lochryan, Lapageria rosea and L. alba are grown on the front of the house, and in a position as nearly south as possible. They are well sheltered and flower well in the summer and autumn.—S. ARNOTT.

Embothrium coccineum.—There are, I believe, few places in Scotland where Embothrium coccineum is hardy. On the west coast, however, a few plants exist, and not only thrive fairly well, but also flower. In Scotland, and in most parts of England and Ireland, indeed, it requires the shelter of a wall to enable it to stand our winters. Only a few plants are known to me in the south-west of Scotland. In one garden where it was cultivated for three or four years against a south wall it ultimately succumbed, but the garden was not in one of the most congenial situations. It was away from the sea and had no special advantages to enable this somewhat tender shrub to flower and live for long. The best places in Scotland are in the counties along the western coast line, where quite a number of other shrubs of more than doubtful hardness succeed when well sheltered.—S. ARNOTT.

Hardy Ferns in winter.—There can be no doubt that many hardy Ferns are yearly sacrificed in carriage-drives and in pleasure-grounds to the rage for tidiness. Under natural conditions the withered fronds fall over the crowns, and not only protect them from excessive wet during winter, but shield the tender young growths from the spring frosts as well. When the fronds are cut over as they cease to be effective it is little wonder that disaster follows, either from damp or from frost. The different varieties of the Lady Fern (*Asplenium Filix-femina*) are especially liable to suffer in this way, and some of the evergreen sorts are apt to suffer from cold winds. In the case of the latter a slight protection of dry Bracken will make the plants safe during the occasionally trying winds of March and April.—KIRK.

Begonia fuchsioides.—Like others of the older Begonias, B. fuchsioides is not now commonly met with. Considering its usefulness this is rather surprising, for the plant is evergreen, and, given good cultivation, may be had in bloom during the greater part of the year. Those who have a stove-house at command will find no difficulty in having pieces full of bloom at Christmas, and if these plants are then

removed to the cooler temperature of the greenhouse the display will be maintained through the spring. Neat little bushy specimens can be had in 5-inch pots, and large, well-furnished pieces may be grown in 8-inch pots. During the winter careful watering is imperative, any excess causing the blooms to drop, while any scarcity results in the falling of the leaves. B. fuchsioides is easily increased from cuttings, a little bottom-heat being desirable, but not absolutely essential. A proportion of peat should be used in the compost for this Begonia, but in my experience this is quite unnecessary, an ordinary every-day mixture suiting B. fuchsioides very well.—W. McG., *Balmac.*

Canarina Campanula.—Of the various greenhouse plants that flower during the winter this is one of the most distinct. From a stout fleshy root-stock are pushed up succulent stems, usually about the month of August, these by mid-winter attaining a height of a yard or thereabouts. They then flower freely, the blossoms bell-shaped, and the colour a soft tone of yellow veined with a reddish tint. After flowering is over, usually about the end of March, the foliage begins to turn yellow, when less water must be given, and when the plants are quite dormant it must be discontinued altogether. Then, if stood on a greenhouse shelf, or in some similar position, it will rest during the summer. As soon as the young shoots make their appearance a good soaking of water should be given, and the plants may be repotted soon after, taking away a good deal of the old soil. They may then be put into 6-inch pots, shifting them into larger ones later on. The growing points may be pinched out to ensure a bushy habit.—W. T.

Chinese Chestnut (*Xanthoceras sorbifolia*).—This small tree, although very handsome when in bloom, does not appear to be quite happy in our country—at least, with me. The group in question occupies a favoured position—a short distance from a high wall facing south—and I have noticed yearly that a great number of the small branches die. During the summer, when in full leaf, the trees are the picture of health, but in late autumn many of the branches are covered with a small brown fungus, such as is often seen on young wood cut during the summer and cast aside, and these branches are found to be dead. The trees referred to fruited this season, but the flowers are the great attraction. In "The English Flower

Garden" it is referred to as requiring a warmer climate than that of Great Britain, and this probably accounts for this unfortunate dying off of the branches.—E. M.

Rose Georges Schwartz at Nice.—Mr. E. H. Woodall writes of this Rose in *The Garden*:—

This autumn, for some inscrutable reason, I have never seen such glorious blooms of that capricious golden Rose Georges Schwartz as are now open. Grafted on various stocks to see which will prove the best, this year, at any rate, *Rosa bracteata*, the Macartney Rose, has proved the ideal stock, while the *indica* major stock, which has often given good results, is nowhere. I wish someone in England would bud it on *R. bracteata* under glass and give it a trial; it is still by far the most sumptuous of all rich golden Roses, with a fragrance all its own, but, being so capricious, it is little known or grown.

I was much struck with the beauty of this yellow Rose at Nice, and hope we shall some day see it thrive in England.—W.

The green Chrysanthemum.—"Kirk's" definition of *Chrysanthemum* (the Golden Flower) if taken literally would deprive us of the many exquisite shades of colour that the *Chrysanthemums* give in the later months of the year. Without question the one prevailing colour in Nature, both in our gardens and in all our varied landscapes, is green, yet how varied, of which one never tires, restful and beautiful in all degrees, from its darkest shade, like our native Holly with its scarlet berries which the deep green intensifies, to the palest green of the Beech in spring. The Snowdrop is purest white, lifting its head often amidst the snow, yet to many its beauty is in its transparent green. Again, think of the beautiful green lines in our Grass of Parnassus; none will deny the beauty of the green in these. Why, then, not admire it in the *Chrysanthemum* (though it be a freak!), which gives us such a pale sea-green with its exquisite translucency?—T. R. C.

The Apricot-tree.—That article signed "G. P. K.," in *GARDENING ILLUSTRATED*, December 18th, makes me ask why he wrote so much when nothing is said of the failure of the tree? For several generations of gardeners the Apricot has been a dismal failure in English gardens, the branches all dying away because grafted on the Plum. In the case of the Apple and the Pear we succeed because they are only grafted on their own kind, so to say, but it is very rarely one sees the Apricot thriving. This is one of the subjects the Horticultural Society might do something to settle for us. They might show us the wild form and see whether grafting on it would not give a better result, and they might also show the effect of it grafted on different kinds of Plum; and also trees from seeds of the best varieties. As some Peaches are raised true from seed so some Apricots might be worth trying in that way. This would be much more worth the Society's while than building laboratories to test questions of much less importance to the public.—W.

Violet Cress (*Ionopsisidium acaule*).—No garden should be without this attractive annual, which is so welcome at this time of year, and stands all kinds of weather. Early in the autumn a few seeds were scattered among newly-planted Carnations. The seedlings have been flowering freely for the past few weeks, giving great promise for months to come. Dozens of minute violet flowers are produced from the little fresh green tufts of Cress-like

leaves. The whole plant rarely exceeds 1½ inches to 2 inches in height, and is, therefore, about the smallest in cultivation. It is charming for scattering over empty crevices in the rock garden or for the margins of borders or paths, in which way its attractive little flowers are borne in great profusion. It is also useful as a groundwork to Carnations, etc., where, being so dwarf, it does no harm, but adds considerably to the beauty of the beds. If left undisturbed it reproduces itself in succeeding seasons, which is a great gain, as in this way a few plants are in bloom the whole year through. The best results are secured from autumn sowings, and a few seeds scattered broadcast during September or early October invariably give a welcome display of flowers two months later. Slugs do not touch it, therefore one of the greatest enemies of autumn-sown annuals is dispensed with, and once sown no special attention is necessary.—E. MARKHAM.

The Portuguese Heath (*Erica lusitanica*).—Although this is not hardy enough for general cultivation in the British Isles, it is an excellent plant for the southern counties, and for certain other mild places. It often grows 6 feet high, and sometimes as much as 12 feet, with a shapely, bushy habit. The white flowers expand in winter and early spring and they are usually at their best during February and March. In the bud stage they are pink, the combination of open and unopened blossoms being very pretty. In some places a really effective display of flowers is produced by Christmas. A native of south-west Europe, it is allied to *E. arborea*, but can be distinguished by its longer and scentless flowers, the blossoms of *E. arborea* having a very pleasant perfume. Although it grows into a pretty, isolated specimen it is seen to the best advantage when planted in large groups. Provided lime is not present in the soil it can be grown in either light loam or in peat, a mixture of sandy loam and a little peat forming an excellent rooting medium. For cutting for indoor decoration, the long branches are very useful.—D.

Sweet Peas.—"M. L. W.," in the issue of December 25th, writes pertinently upon Sweet Peas. The evil which lovers of the flower foresaw years ago is now an accomplished fact, and now there is the inevitable reaction in favour of smaller and more sweetly-scented blooms, and of a more natural method of cultivation. In short, there is again a revival in favour of Sweet Peas as they were before raisers and exhibitors transformed them from the favourites of the garden of a quarter of a century ago into the monstrosities of the show bench. It would be idle to deny that good has not been accomplished by the hybridist and the specialist, but when form and sweetness have been swamped by size and—to be quite candid—by coarseness, the lover of Sweet Peas is justified in protesting. Another evil which has crept in is the quite unnecessary multiplication of "too-much-alike" varieties—many of them of doubtful value at the best. The latter fact has been increasingly borne in upon me year by year when testing or experimenting with the novelties of the season. Sweet Peas, and, equally with them, Asters, now occupy so much space in catalogues that it is not only a weariness to read over the lists, but a source of perplexity to those unacquainted with the subject who may be desirous of making a selection. Like "M. L. W.," I look forward to the older and saner way of growing Sweet Peas, and, I think, in future seasons 1915 will be memorable as the year which saw the beginning of the great slump in Sweet Peas.—K. BRIGHT.

FRUIT.

TOO MANY APPLES.

MANY, no doubt, will agree with the note in November 13th issue (page 684) as to there being too many Apples. That there are so many kinds catalogued is no doubt due to the demand for them by, perhaps, a small section of the purchasing public. Trade exhibitions, too, contribute materially to the long lists of Apples. On the same page "Kirk" mentions Stone's, or Loddington, as being a disappointing Apple. This is undoubtedly true. This variety, which ripens during September and early October, has been encouraged, presumably, for no other reason than that it grows to a large size. If kept until November it is of little value. Remembering how many other Apples there are at this season, what purpose is there in retaining a kind that has such a fleeting season? If a dish of handsome fruits is needed for exhibition in early October, Stone's may supply it, but this is the limit of its usefulness. I was led to plant this from seeing it at a show in early autumn, but its short season has condemned it. The same remark applies to Warner's King, Lord Grosvenor, and Cox's Pomona, so often seen on the show table. Peasgood's Nonsuch comes into the same class. This is usually a very shy fruiting variety and does not keep well.

It would almost seem that the question of flavour in a cooked Apple has been left out, and it would seem, too, that sweetness has not been looked for. No better or more simple test of natural flavour can be made than when plain baked in a suitably heated oven. Another point in cooking Apples is that most persons regard size as all important. There are many cooking varieties of Apples that the average person could not possibly accept in a raw state as dessert. There are people who prefer a Wellington to a Cox's Orange Pippin or a Blenheim.

Mr. Ballard, in the same issue, alludes to what he describes as "the unhealthy demand for gaudy colours and huge size at the expense of all the really finer qualities." In this, again, there is much truth. The Worcester Pearmain has always remained a puzzle. Why there should be such a demand for this Apple for no other reason than that it has an attractive exterior I fail to see.

If there ever was a period when sweet cooking Apples were valued we should certainly expect that the almost prohibitive sugar prices now prevailing would bring them into prominence. W. STRUGNELL.

NOTES AND REPLIES.

Peaches and Nectarines.—It is customary to take these trees from the wall annually, so that the wood can be thoroughly washed and the walls cleansed, as many insects that infest these trees hibernate in any hole and crevice they can get into during winter. Where the trees are trained to wires (and this is by far the best method) the necessary pruning may be done before the trees are loosened, and it can be better determined what amount of growth can be dispensed with, especially in the matter of a large branch here and there, which at times is the better for removal. The shoots that will fruit next year are those that were made during the past summer, therefore reserve sufficient of these for refilling the wall space, when the shoots are replaced in their proper positions. Red-spider and the black aphid are the two worst enemies of the Peach. These are found on the

young and old wood alike, so that all the shoots need to be carefully washed, using a soft painter's brush or sponge for the purpose. In treating the fruiting wood be careful to work the sponge or brush towards the point of the shoot or many of the buds will get injured or rubbed off. Gishurst compound will be found a very suitable and effective insecticide for the purpose. Trees badly infested with these insects should be gone over a second time as soon as the first washing has dried, choosing a dry day for the work.—F. W. GALLOP.

Passiflora edulis.—This is easily grown and fruited under glass in a temperature

was more satisfactory where bottom-heat pipes were available to give warmth in winter to start the plant earlier into growth. Any good loamy compost will suit.—E. H.

Altering the garden.—Many are finding it necessary to make an effort to reduce expenditure, and the garden, being looked upon as a luxury, comes first. But in our garden making or altering we do not want to break away altogether from old associations, especially in connection with simplicity and nearness to Nature. I have seen the value of introducing fruit-trees into the precincts of the house, especially in the case of what I may term the wild

TREES AND SHRUBS.

OZOTHAMNUS ROSMARINIFOLIUS.
This pretty Australian evergreen shrub is by no means well represented in gardens generally. Unfortunately it is not thoroughly hardy in the British Isles, but if planted in a sheltered position will thrive in all but the coldest districts. It is by no means fastidious as regards soil and will thrive in rather stiff loam to which a little peat and leaf-mould have been added, provided there is good drainage, which is essential. The best position is one having a south or south-west aspect, as it is only when the wood becomes thoroughly ripened that the best results are obtained. On no account should the position be one exposed to cold winds or the plant will suffer in spring, when growth is tender. The flowers are valuable for cutting, as they can be obtained with long stems for vases, remaining fresh for a long time. The sprays can also be cut and dried for winter decoration.

F. W. G.

MISTAKES ABOUT IVY.

The Ivy is the most beautiful climbing evergreen of the northern world, and a precious gift for our land, as we can grow it everywhere. In other countries which are not so happy in possession of it, as in much of North America, they have to keep it in the greenhouse. It is a precious gift of Nature not always esteemed at its true value, and sometimes ill-treated. People in my part of the world are very careful to cut it off the trees, but this, I think, is a mistake. One would not, of course, like to strangle some new kind of tree, but in an ordinary wood or plantation it seldom does any harm. There are over fifty beautiful varieties of this plant. In the case of the Irish Ivy and some others, they have botanical names, which is needless and wrong, as they are all forms of the same plant which is wild in our woods. It is best, therefore, to keep to simple English names. Variegated forms are no good, but many of the green Ivies are beyond price. The wood is the place for the Ivy, which should not be much grown in gardens, as it is too vigorous, excepting the tree forms. It is such a vigorous plant that putting it on houses is almost always a mistake, though perhaps on houses on the sea cliffs it may serve to keep the wet out, but if it gets its little fingers under the roof or tiles it is a great destroyer, and many old castles and houses have been thrown down by it. There is room on the river sides and banks for Ivy without putting it on a house of any kind. Instead of destroying Ivy where it grows in a wood it is wiser to pick out some favourite form that has been admired in the garden, perhaps, and take the young shoots and put them at the bottoms of trees with a spadeful of earth, or a brick or something, and let them climb up the tree. Some of the nobler forms of Ivy, like the Amoor, are very fine in leaf, and give beautiful effects on trees, and so also the little and delicate kinds, and the bronzy ones. For bowers and screens it is very useful, but most beautiful by far in the woodland or shrubbery. The common kind abounds in our woods, and forms a carpet in many of them, and then climbs according to its own sweet will. Where there are no evergreen trees, as in our ordinary woodland, the effect of Ivy is a great relief, and the shoots make a welcome shelter for birds.

W.

Gordonia altamaha.—Flowers are still opening on this beautiful southern tree. They first appear in September, and open

Ozothamnus rosmarinifolius at Lilford Hall, Oundle, Northants.

of 60 degs. or so, but the best coloured and best flavoured fruits are grown in the warmest house. I had plants at the same time both in the stove and also in a large conservatory. The plant in the large cool-house bore well, but the fruits were thick in the shells and otherwise inferior. When the fruits in the warm-house were partially coloured I thinned them before they were ripe, and they were preserved whole in sugar and were much appreciated for the dessert. Young plants are easily raised from seeds, but do not fruit so soon as plants struck from cuttings of pieces of half-ripe wood in summer, or whenever they can be obtained. The fruiting

garden. The cottager understands the value of fruit-trees and bushes in the garden attached to his cottage. Amateurs are turning their attention more to fruit growing, and there are places suitable for cordons and other kinds of trained trees. In open places I should plant standards on free stocks of Pears, Apples, and Plums. I remember a garden in the country where an old Pear-tree formed a conspicuous feature all the year—in the spring and summer flowers and fruit, and in the autumn for the beautiful colour of its foliage when dying. It may be mentioned that the Pear is a long-lived tree.—E. H.

in succession for fully six weeks. *Gordonia* is related to the *Camellia*, and the pure white flowers, which vary from 3 inches to 3½ inches in diameter, although more cup-shaped, resemble single *Camellia* flowers. This small tree was discovered in 1765 near Fort Barrington, on the *Altamaha* River; it has entirely disappeared, however, as a wild plant, and it has only been preserved by the specimens cultivated chiefly in the neighbourhood of Philadelphia, where it was sent by its discoverers. There are well-established plants on Hickory Path, near Centre Street, and on Azalea Path, and in these sheltered positions the plants are doing well and have not suffered at all in recent severe winters. This *Gordonia*, however, grows more rapidly, and to a larger size, in the middle States, and there are many good specimens in Pennsylvania gardens. —“*Arnold Arboretum Bulletin*.”

The Manna Ash (*Fraxinus Ornus*).—This Ash belongs to the group popularly termed Flowering Ashes. It is a native of Southern Europe and Asia Minor, and has been grown in this country for at least 200 years. In a state of Nature it grows about 60 feet high, and there are trees in this country of a similar height. It usually has a rather short trunk and wide, shapely head, clothed with ample leafage. In May or early June large panicles of fragrant flowers are borne freely, the conspicuous part of the bloom being the narrow white petals. Fine clusters of yellowish or reddish fruits are borne during August and September. It is an excellent tree as an isolated specimen for lawn or park, as it thrives in a great variety of soils and gives little trouble. The best trees are usually found on loam of good quality that is permanently moist. Several forms have been given varietal names, but generally they are no improvement on the type.—D.

The Phillyreas.—The *Phillyreas* form a useful group of evergreen shrubs or small trees from the Mediterranean region. They are easily increased by cuttings of half-ripe shoots inserted in sandy soil in a close frame in summer, whilst seeds also vegetate freely. Four species have been described. Of these, *P. decora*, sometimes called *P. Vilmoriniana*, is the most distinct. At one time it was increased by grafting it upon stocks of the oval-leaved *Privet*, but plants so raised were short-lived and cuttings root quite well. It forms a spreading bush and bears fragrant white flowers from axillary buds in April or May, the flowers being followed by black fruits. *P. angustifolia* is a dense bush growing 6 feet to 10 feet high, and has white flowers. *P. rosmarinifolia* has very narrow leaves. *P. latifolia* sometimes forms a small tree 18 feet high, with a trunk a foot in diameter. It bears whitish flowers which are not very conspicuous. *P. media* appears to be little more than a variation of *P. angustifolia* or *P. latifolia*. There is little to choose between the various species, though *P. decora* is perhaps the most attractive.—W. K.

Kelreuteria paniculata.—When selecting trees for positions on lawns or other prominent places about the garden this summer-leaving species should be kept in mind, for it is attractive in leaf, flower, and fruit. Moreover, it does not outgrow its position very readily, for though fully developed examples may be 30 feet or 40 feet high, with a wide-spreading head, such dimensions are not attained until the trees are of considerable age. A native of China, it has been grown in this country for about 150 years, and fine specimens are to be found in various old gardens. A

very large one existed a few years ago on the slopes near Windsor Castle. In July large heads of yellow flowers are produced, the inflorescences being branched and often a foot or more long and nearly as wide. In very sunny years good crops of fruit are produced. It is a sun-loving tree and must be given a position sheltered from cold winds, but not shaded in any way.—D.

The American Mountain Laurel (*Kalmia latifolia*).—The various kinds of *Kalmia* are very beautiful and suitable for almost any part of the country where lime is not present in the soil in any appreciable quantity. Of the different kinds *K. latifolia* is one of the best. It varies a good deal in habit, and in some gardens scarcely exceeds 4 feet in height; elsewhere it may be as much as 10 feet high with a very wide spread. The flowers are white suffused pink or sometimes rose-coloured, a good deal of variation being noticeable in a group of seedlings. The flowering time is June, when it is certainly one of the most beautiful shrubs in the garden. Wherever *Rhododendrons* thrive it may be expected to give good results, but it is, perhaps, most at home in the moist, mist-laden valleys of the west. In Sir John Llewelyn's garden near Swansea a number of very fine examples exist. Although seedling plants grow very slowly for several years it is much better to rely upon seeds for propagation than to attempt any other method. The next best way is layering. Imported plants dug up from the hill country of the Eastern United States have been tried, but they are rarely satisfactory, growth for several years being very slow. Like other kinds of *Kalmia* this possesses poisonous properties, and plants and cut branches should not be so placed that they can be eaten by stock.—D.

The Tulip-tree on the lawn.—This is a very handsome tree, especially when in flower, but considering that it was introduced from North America in 1663, it is not so common as one might expect. I have seen some good specimens in the south and west of England, and I have met with it in the eastern counties, but I think more might be planted. Try it first in sheltered places where the drainage is right.—E. H.

PLANTS AND FLOWERS.

FERNS.

HARDY FERN NOTES.

THE COMMON HART'S-TONGUE.—I have just been looking at a plant of this which has occupied a shady position on rootwork for some years. It covers more than a square yard of ground, has about 100 fronds each some 2 feet in length, and exhibits a richness of verdure not, I think, to be equalled by any other member of a very numerous family. I doubt if the value of this native species is fully realised. The numerous crisped and lacerated varieties are favoured by growers of hardy Ferns, but the parent form is too common to find a place with them. Can, however, any reader of this paper name a Fern which in luxuriant verdure surpasses it? If it came to us now from a foreign land it would, without a doubt, be in great demand, but as it can be found growing in our hedgerows and woods it is not held in much estimation. There is, however, a vast difference in this Fern in its highest form and when there is an absence of culture. Because it is of an accommodating nature it is generally used as a kind of stop gap plant, any impoverished bit of ground being considered good enough for it. Let me plead, however, for better treatment. Give it some good nourishment—it dearly loves a bit of rotten dung—and you will not regret having spent a little time on the old Hart's-tongue.

HYPOLEPIS MILLEFOLIUM.—A pretty little Fern this for adorning bare spaces. It has the same manner of growth as the *Bracken*, and, when established, grows at a tolerably rapid rate. It also has an accommodating nature, thriving, of course, in the shade, but living and looking well when exposed to sun. I put some plants on a very dry border early in spring. They were not watered, but came along very well during the long dry spell, and now, under the influence of abundant rainfall, they look very nice and are covering the ground. It grows about 9 inches high, the fronds being finely cut and of a pleasing glaucous green. It ought to be useful for clothing bare spaces near and under trees.

THE COMMON POLYPODY.—Few, probably, know how impressive this Fern is when seen in large breadths and covering many square yards of ground. I have only once seen it in this condition, and came to the conclusion that its decorative worth is not fully recognised and that used in this way it is one of the finest dwarf evergreen plants we have. Broad and rather steep banks bordering the drive leading to the mansion and several hundred feet in length were completely carpeted with this Fern. I cannot say if it was planted or if advantage had been taken of the fact that it was indigenous. The *Polypody* was frequently found growing wild in the district, but it has almost disappeared, owing to the operations of the basket-men, as they are called here, who have rooted out Ferns, Primroses, and everything they could get to sell in the neighbouring towns.

FERNS AND LILIES.—A member of the household conceived the idea of converting a bare, rather unsightly corner into a thing of comparative beauty, and, I am bound to say, has succeeded. This place forms an angle between a tall *Privet* hedge, with big *Willows* at the back, and the dwelling, which is covered with old-established *Ivy*. Seeing that the soil was, in a great measure, filled with roots, the prospect of successful culture did not seem rosy. The ground, however, was well broken up and planted with Ferns, a variety of the *Hart's-tongue* named *projectum*, which has broad, upright fronds and is much dwarfer than the type, and some of a lacerated kind being chosen. The result is good. An unsightly spot has been converted into a verdant corner. Moisture was, of course, given as required, and the plants are now (mid-August) throwing up secondary fronds. The advantage of using the *Hart's-tongue* varieties is that they remain green all through the winter. It has occurred to me, however, that this would be an ideal spot for *Lilies*, which are always happier in intimate association with other forms of plant life. I think of planting *L. tigrinum*, *L. pardalinum*, *L. speciosum*, and *L. Szovitzianum*. They will have shelter from spring frosts, cold, rough winds, and hot sun, and ought, I should imagine, to be happy. BYFLEET.

NEW FERNS OF 1915.

ONLY three were honoured, and they are all varieties of British species. On October 26th a first-class certificate was given to a grand variety of our native *Hart's Tongue* bearing the name of

SCOLOPENDRIUM VULGARE CRISPUM SPECIOSUM.—The long, gracefully-arching fronds of this are beautifully crisped.

SCOLOPENDRIUM VULGARE PLUMOSUM PERRY'S VAR. is a very handsome plumose variety much divided at the tips. Award of Merit October 12th.

POLYPODIUM DRYOPTERIS PLUMOSUM has broad, overlapping pinnules of a particularly soft tone of green. Award of Merit September 14th.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

THE ROCK GARDEN AT BELLE ISLE.
 BELLE ISLE is a quaint, old-world place on Lough Erne, where the "Annals of Ulster" were written in the year 1498 A.D. (the ancient name was "Ballymacmanus"). When we came in for this "Land of Promise" twelve years ago the old house was partly surrounded by monster trees which kept out the view on one side, though towards the south stretched the lake, with its changing shadows and moods, four miles across to the rugged hill of Knockninny (the old deer park of Belle Isle).

It requires determination before daring to fell a fine old tree, but we had to harden our hearts, and my husband had several cut down. This opened out a slightly inclined stretch of rough parkland with a background of more old

(though not very large) stones arrived in cots from the islands, and then a beginning was made; a rough "stratum" was built up, and, as the ground there was swampy and held moisture (the subsoil being of stiff blue clay), my ambitions soared to having a rocky pool. So under this first "outcrop" of rock I marked the outline for the pool, each small bay or promontory having its "reason" or "cause" in some outjutting rock, etc., etc., opposite. This was the modest beginning of what has since spread into a very satisfactory piece of rock and water gardening, which, though not finished, is a decided feature now, as the brilliant colouring of *Erica carnea* (alpine Forest Heath) and *Erica hybrida* which were planted among, and falling over, the outcrop of rocks, reflects brilliantly in the pool beneath. The *Ericas* were planted in turf-mould and sand (which had to be carted several miles),

rocky steps up over the artificially-made heights (though I hope they look as if they had been there always) to the moraine I made last autumn (after having been fired by Mr. R. Farrer's description of one), and which has proved a safe home through last winter's torrents for some rather difficult alpinists. Here *Cotoneasters* crown the rock heights or are reflected in more pools below, and throw shadows over the rocky caves which I have found of such use in planning out my "picture." These *Cotoneasters* have been a great help to me, and I use all kinds, from the old *Cotoneaster microphylla* and *C. horizontalis* to the tiny *C. adpressa* and *C. congesta*, delightful little rock-hugging shrubs a few inches high. The prostrate *Junipers*, dwarf glaucous shrubs, with the larger *Cotoneasters* cluster over the rocks and satisfy the eye with their quiet, subdued colouring. The

Part of the rock garden at Belle Isle. From a photograph sent by Mrs. J. Porter-Porter, Belle Isle, Co. Fermanagh, Ireland.

timber, amongst which were gnarled Oaks shadowing what used to be "ye olde fish ponds" of Belle Isle and the old walk to the Temple Hill Wood. This felling of trees gave us air, light, and shadow, but we still wanted colour and "feature." I longed for a

ROCK GARDEN to be where the cattle now grazed; the site (looking S.E. and S.W.) was suitable, as were the surroundings, and before long my dreams began to be realised. I gave constant thought to the planning of this future rock garden, studying the lie of the land, the grouping of trees, the background, and the side views. My idea was to have a rough outcrop of rock, ending abruptly here and there, running up into miniature hills, and dwindling into valleys. I imagined them clothed with alpine Forest Heaths and with many others of my favourite rock plants, all growing in long, irregular drifts, or hanging over the boulders. The first loads of beautiful water-worn

and are yearly spreading. They were in glorious bloom last March. A little rocky promontory is a safe home for small *Primulas*, such as *P. rosea*, *P. involucrata*, and *P. farinosa*. Here also is a happy specimen of the weird Canadian pitcher plant—*Sarracenia purpurea*—and crimson *Mimulus* ramps about. The rough foreground is still very unfinished, but I hope before long to make it into a suitable home for low-growing, moisture-loving things, and to have the bank to the right aglow with tall crimson *Primula japonica* and *P. pulverulenta* among groups of *Elymus giganteus*, *Spiræas*, *Saxifraga peltata*, etc. This small beginning fired me with the ambition of having a wider rock garden. Here are more *Ericas* in long drifts among the Mossy grey rock steps and boulders, which also shelter *Ramondias* and all sorts of tiny treasures that love shade and moisture.

The illustration shows my ambitions partly realised and a continuation of the

rough, irregular steps (shown in the illustration and which I flatter myself look like the rocky, dried-up bed of some former mountain torrent) are clothed with *Arenaria balearica* and with my still more beloved *Arenaria purpurascens*. Dwarf Mossy crimson *Saxifrages* creep into the hollows, and trailing alpine *Phloxes* with their beautiful pink and mauve stars fall over the sunny sides of the rocks and mingle with the dwarf pink-flowered *Dianthuses*, such as *cæsius* and *arvensis*. Dwarf *Campanulas* ripple among the steps, and large, irregular colonies of mauve Mountain Violets rejoice your heart from the first days of spring well into the autumn (and some even into the depths of winter). I must specially mention a delightful one I got in February last (*Viola pseudo-gracilis*), which has flowered profusely ever since among stony débris. In the rougher parts of the rock garden these two useful Mountain Violets (*Viola cornuta* and *V. cornuta* Papilio)

clothe the waste spaces and seed themselves everywhere. Sea Pinks (or Thrift) are useful, especially the rose-coloured ones, and their evergreen, tufty foliage is bright in the winter. *Ionopsidium acaule*, a beautiful little annual sown at intervals through the spring and summer between the rocky steps and boulders, gives you rills of fascinating mauve flowers (about 2 inches high) for months at a time. Some were in flower here, constantly through the winter.

I allow no yellow, orange, or salmon-pink flowers in or near my rock garden. Some rock gardens are ruined by these colours mingling with the rose-coloured blooms of such things as *Erica carnea*, pale pink rock *Dianthus*, etc., etc., which, with an over-abundance of unnecessary rocks, give a fussy and incongruous look which is disturbing to the eye. Yellow reflects sunlight and is beautiful, but not when clashing with pink or rose colour. As many of the plants in my rock garden are *couleur de rose* I aim at large stretches of soft mauve, grey, white, and blue contrasting smoothly with, and running into, the brighter pinks and crimsons. Beyond the rock garden and over another pool is the other "vista" of my ambition, but as it does not belong to our subject I dare only say a few words about it. Here I have planned my

ROSE DELL, going off into the shadows of the trees in the far background, broken here and there by great waving colonies of the hardy New Zealand Flax (*Phormium tenax*), with their great glaucous leaves, bold clumps of tall, pale-blue *Delphiniums*, towering mauve-plumed *Thalictrums*, giant *Rheum tanguticum*, with its coral-red flower-spikes, or seed-heads, over 9 feet high. Here, too, in the far background (for the autumnal picture) are *Tritomas* between clumps of crimson and purple-leaved Japanese Maples. In the waste sunny spots are tangles of the common Sweetbriar and Honeysuckle, and to carry the eye further back are rugged poles here and there up which climb crimson and pink Penzance Sweetbriars, Blush Rambler Rose, and the glorious white, wild Himalayan Rose, *R. Brunoni grandiflora* (this is the only Rose on which I leave the seed vessels, as they brighten the long winter months with their glowing and abundant mass of hips, nearly as bright as Holly-berries), and a wealth of other Rambling Roses, with pale mauve and pink autumn *Phloxes* at their feet (*Selma* is one of my favourites). Long drifts or colonies of old, rather rugged Lavender bushes stretch here and there among the Roses and amalgamate all. Flat, water-worn stones from the lough side are used here and there to give dry footing. I find "Rambling Rector" another capital Rose for sending up a tree. I planted one three years ago to a tall old Spruce, and it is now half-way up, and is fighting there for supremacy with a *Clematis montana* and a Virginian Creeper.

Looking back on what used to be an uninteresting, nearly flat stretch of rough park land, this present rock garden (with Rose dell in the background), as it is now, is satisfying to the eye, and though still very unfinished is now a thing of joy. This rock garden is unlike any I have ever seen. A studied wildness has been my aim. I am thankful that my lot has fallen in a beautiful, unspoilt, old world place, and the labour of making this rock garden has been one of love. To quote from Mrs. C. W. Earle's "More Pot Pourri," "the best thing in old age is to care for nothing but Nature—our real old mother—who will never desert us, and who opens her

arms to us every spring and summer again, warm and young as ever, till at last we lie dead in her breast." J. P. P.

Tanakæa radicans.—Some experience a difficulty in growing this Japanese alpine. It should have a moist position if the best results are to be obtained, and delights in a damp, shady situation where it can grow freely. Peaty soil it prefers, but it will also do well in loam and leaf-soil, with a little sand.—S. ARNOTT.

INDOOR PLANTS.

POINSETTIA PULCHERRIMA.

FROM November to the end of January flowers are scarce and valued accordingly. However, during this dull time the Poinsettia is to be had in perfection. The gorgeously-coloured "bracts" of the most intense scarlet are attractive during the shortest days, and a few of them brighten up stove, conservatory, or rooms in the most pleasing manner.

CULTURE.—The flowers, as a rule, are over by the end of January, and from that time until the beginning of May the plants will remain dormant under the plant stage of a warm house. They will not need any water or other attention at all at this time. About the beginning of May they are brought out from beneath the stages, watered thoroughly, and then placed in a frame or house where the temperature is about 65 degs. Here they will speedily begin to grow, and emit young shoots all up the stems. When these are about 2 inches in length they are taken off as cuttings; each one is detached with a "heel"—i.e., a very little piece of the old wood attached—and they should then be inserted into the smallest-sized 2½-inch pots, filled with a half-and-half mixture of leaf-soil and sand. They are then plunged up to the rim of the pot in Cocoa-fibre in a hotbed or Cucumber-house, where the bottom-heat is about 70 degs. Here they are not allowed to suffer from want of water, although they do not require much of this until the roots are formed, and they are also shaded from bright sunshine. Roots are soon made, and they are then withdrawn from the bottom-heat and placed on a shelf in the pit, and in a week or so after this shifted into larger-sized pots. From 2½-inch pots they are generally put into 3-inch ones, and from the latter into 6-inch or 7-inch ones, and in this size they are allowed to bloom the first year. In

POTTING, use a rough mixture of turfy loam, sand, and leaf-soil. Proper drainage is of the utmost importance, and firm potting adds to success in culture. Poinsettias lose much sap when injured, and this, having a weakening tendency, must be avoided as much as possible. After potting, keep close and shaded from bright sunshine for a few days; afterwards they will bear all the light possible. From the last potting until the middle of September they do remarkably well in a cold frame, and they should never be grown in a strong heat at any time in summer, as this causes them to make long, straggling growths, which are neither ornamental nor useful. Dwarf, sturdy shoots always produce the finest heads, and short plants are always more valuable than long ones. Another way of securing serviceable plants is to cut the old stems down to about a foot from the bottom, and allow all the side-shoots which sprout out to grow. In this way some of them may have six, eight, ten, or twelve shoots, and as each of these will produce a showy head, very attractive plants are the result. When they are treated in this way it is best to repot the old plants as soon as the young shoots are a few inches long, and they

may be potted again when growth is more advanced. As a rule, those branching specimens flower well in 8-inch and 10-inch pots, and apart from allowing the shoots to remain on instead of taking them as cuttings, these plants are given the same treatment as those raised from cuttings. In the autumn they are taken into a warmer and drier atmosphere, and here they soon develop their brilliant heads. Throughout all the period of their growth the greatest attention should be given to watering Poinsettias at the roots, as allowing them to become dry in any way causes the leaves to fall prematurely, and then the heads are poor.

NOTES AND REPLIES.

Lasiandra macrantha.—Though this splendid autumn-flowering shrub is now by the latest botanical authorities called *Tibouchina semi-decandra*, it is far more generally known in gardens by that at the head of this note. At one time it was considered that the temperature of a stove was necessary for its successful culture, but it can be well grown and flowered in the greenhouse. The typical kind is of a somewhat rambling nature, and is seen to considerable advantage when trained to the end of a glass structure or in some similar position. The large salver-shaped blossoms are of a rich purplish-blue tint. There is, or was, a very distinct form, which appears to have almost, if not quite, dropped out of cultivation. In this, known as *Lasiandra macrantha floribunda*, the flowers are very large and richly coloured, while they are freely borne when the plant is comparatively small. This variety requires more careful treatment than the typical kind, which can be readily struck from cuttings. They need to be stopped when young in order to ensure a bushy habit.—W. T.

Garden hobbies.—Some years ago I had an amateur friend who possessed one small glass-house, and his ambition was to grow plants that he could attend to in his spare time, and after much thought he decided to try a few of the smaller Cacti, *Mamillaria*, *Cereus*, etc. Some of the last are suitable for baskets. Epiphyllums also may be grown in baskets or pots and suspended near the glass, and will flower in winter in a temperature of 50 degs., or between 50 degs. and 60 degs., and may be grown in a cool greenhouse. They can be placed in the open air in summer to ripen the growth, and will flower all the better for the change. They are usually kept rather dry in winter to prolong their rest, but this does not refer to the winter-flowering species of Epiphyllums, which require rather better compost than the others, though all require plenty of drainage in the shape of broken oyster-shells and crushed charcoal.—E. H.

Luculia gratissima.—This is one of the bright shrubs in the conservatory at this season, and it makes a better specimen planted in the border than when grown in a pot. It makes a good wall shrub, and is easily trained and kept in condition. Whatever pruning is required is done after the flowers fade, and a little shortening back then is beneficial. Some find it difficult to root from cuttings. When the shoots are getting a bit firm they will generally root under a bell-glass, with care in watering and wiping the damp from the inside of the glass every morning; but the surest way of obtaining a stock of young plants is to put a young plant into a frame where there is a little warmth and layer every young shoot.—Every bit will make a plant.—E. H.

The berried Solanums.—These are not now so popular as was the case years ago, Solanums having, to a great extent, been superseded by flowering plants. Yet, they are attractive in their way, and neat, bushy specimens in 5-inch or 6-inch pots are not without value. Plants lifted some time ago, potted up, and placed in heated, but airy, pits are now filling their pots with fibrous roots, and can be removed to the greenhouse at any time. Careful watch must be kept for aphids, to which the plants are subject, and which soon disfigures them.

OUTDOOR PLANTS.

CLEMATIS NELLY MOSER.

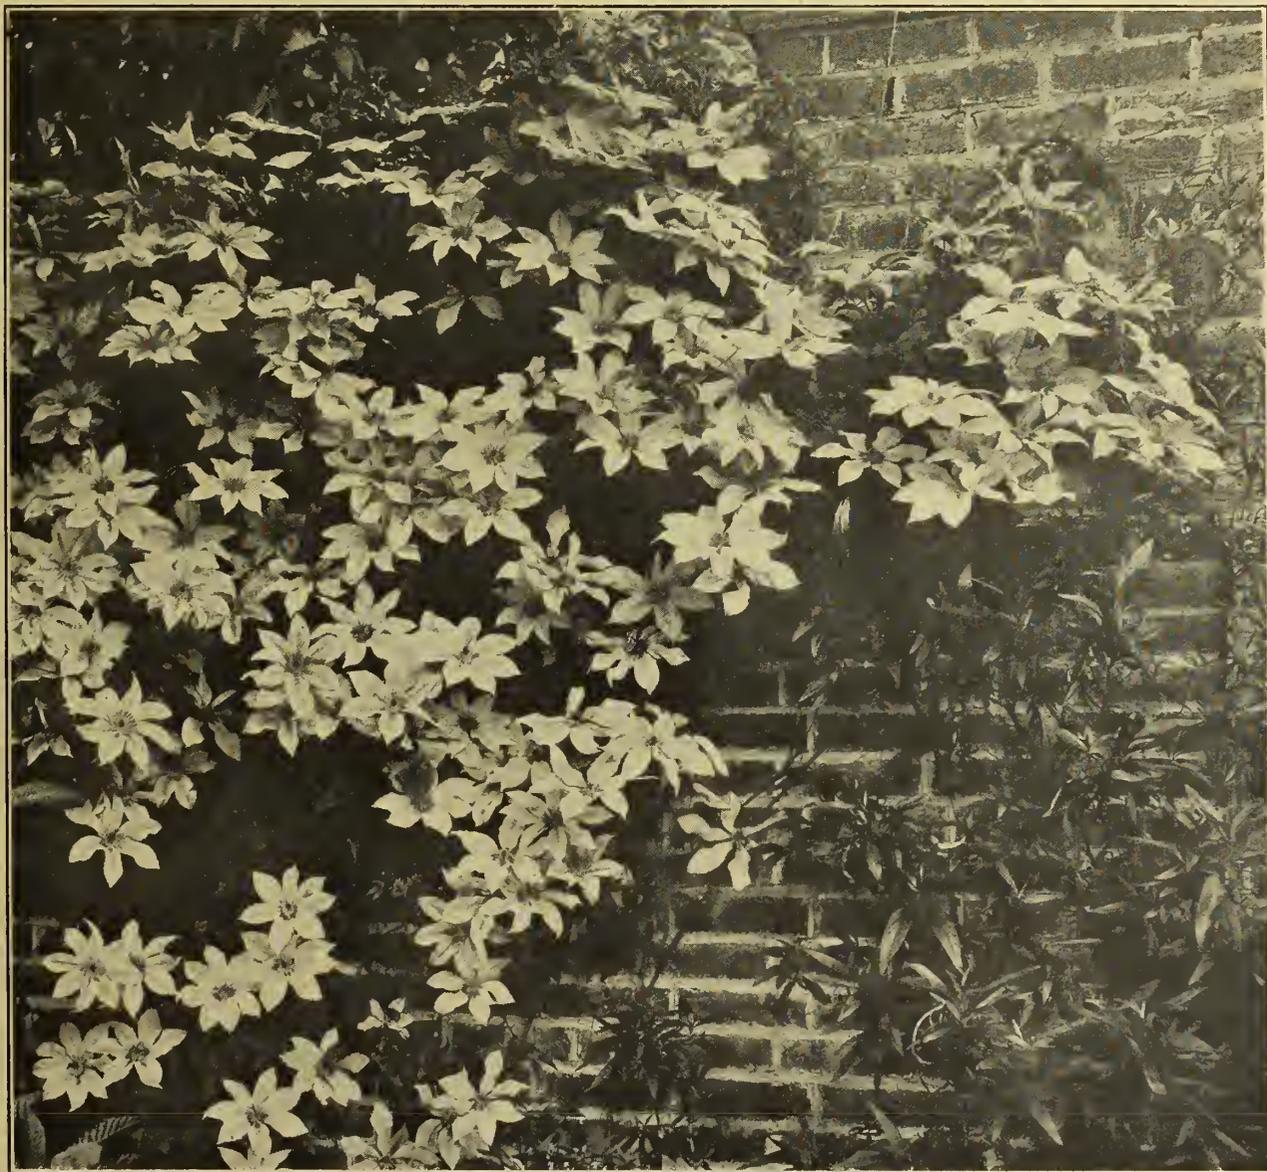

This Clematis combines all the good qualities of the lanuginosa hybrids, certainly the most aristocratic branch of the family. It is of vigorous growth and not prone to disease. The white flowers flushed with pinkish mauve have a striking red bar in the centre of each petal. Its early summer glory is followed by successional flowers on the secondary growths until the end of October. The plant shown in the illustration is growing on a west wall, in a 9 feet border, among dark-foliaged

greatly from *M. didyma*. The differences are noticeable in many respects, the height being greater, while the size and colour of the bracts and calyces vary from those of the more usually-grown sort. The corollas, too, are purple or reddish instead of the scarlet of *M. didyma*. It is, however, equally easy of cultivation, and attains to a height of nearly 4 feet; indeed, in the autumn I noticed in a Glasgow park plants which exceeded this height.—KIRK.

The Old World Dog's Tooth Violets.—Beautiful as are the New World species of Dog's Tooth Violets, as represented by such charming plants as *Erythronium*

varieties will give good results. A scarce Old World *Erythronium* is *E. sibiricum*, which has large flowers and prettily-mottled leaves. The colour of the flowers is a kind of pink. These *Erythroniums* flower in spring and do best in loam and leaf-soil. They move best just when the leaves die down, but are generally purchased with other early bulbs. With the exception of *E. sibiricum* these Dog's Tooth Violets are cheap, and should be planted about 3 inches deep, top-dressing with a little soil annually.—S. ARNOTT.

Replanting Montbretias.—One of the best arguments in favour of the biennial lifting and replanting of colonies of Mont-

Clematis Nelly Moser on a wall at Nymans.

shrubs. No animal manure has been used in its cultivation. A quantity of decayed refuse was dug into the border when it was made, two or three years before the Clematis was planted. A mulch of leaf-mould is given during the summer months. Little pruning is required, the dead points of the shoots being cut back to growing buds in February. Clematises love to cling by their leaf-stalks, and, when grown on a wall, strings should be strained from fixed wires or Bamboos to enable them to do so. J. COMBES.

Nymans Gardens, Handcross.

Monarda fistulosa.—This is sometimes styled the Wild Bergamot, and differs

giganteum and others from the American Continent, those from the Old World deserve consideration. They are charming flowers, even though their North American sisters have a still greater delicacy of appearance and more refined beauty. These *Erythroniums* are quite attractive in their season, their only fault being that they are rather too evanescent. *Erythronium Dens-canis* is the best-known Old World species. There are two forms of this, that known as the grandiflorum set being the finer. The flowers vary from deep rose-purple, through violet, rose, and pink to white. Some named varieties, such as Franz Hals and a few others, have been selected, but any of the grandiflorum

bretias came under my notice in the autumn. A border of perennials had been cleared out in the previous winter. Among the hardy plants were several good clumps of Montbretias, which, when the lifting was going on, were taken out as carefully as possible. Some stray corms escaped, and as they came up strongly in spring they were permitted to develop. The result was surprising. These Montbretias were the best in the garden, reminding one of miniature Gladioli. It would seem, therefore, that the more thinly the corms are planted the better are the results, and even when biennial replanting is resorted to it would appear that there is still a tendency to allow too little space.—K.

VEGETABLES.

FORWARDING EARLY PEAS.

It may be thought that this date (December) is full early for this work, but not so, as with cold frames the germination takes some time, and much depends upon the shelter afforded. We have no lack of excellent varieties for the work, as there has been a great gain of late years. I do not advise the very small podders, such kinds as May Queen, 2 feet to 3 feet high, an early Marrowfat and very hardy, will compare favourably with the smaller growers as regards earliness. From a warm border even in the Midlands I have had this variety, given the protection of a cold frame at the start, the third week in May. Other excellent early Peas are Early Giant, a 3 feet to 4 feet variety, and Ideal, of nearly the same height. Duchess of York is a little taller, but an excellent variety. Empress of India is a great gain on the older small round Peas, which have none too much flavour and age so quickly. Another very good cropper and of good quality also is World's Record. I do not think any variety can beat it for crop, but it is a few days later than May Queen. First of All is a favourite in many gardens for early work. This is just over 3 feet, but very early and a robust grower. There are others, such as The Pilot, 3½ feet, Laxtonian, a dwarf variety but excellent, only 18 inches to 2 feet in height, and useful where space is limited, and the older well-known Gradus, excellent if a good stock is secured. This is 3 feet to 4 feet in height. If even dwarf forms are liked there are good selections, but I prefer those noted above, as I think the quality better and they give large pods. Dwarf kinds, such as Little Marvel, Harbinger, Reading Wonder, Excelsior, Chelsea Gem, and Laxtonian, named above, are from 1 foot to 2 feet high, of good quality, and very early.

By giving protection at this season there is a great gain. I also prefer new seed, as the seedlings are more vigorous. For very early gatherings I have in some years sown in December, but with cold frame protection I advise sowing as early in January as possible. Even then a little care is required at the start. As most growers know, there is but little gain in sowing thus early unless frost is kept at bay, hence the many failures when seeds are sown too early in the open, even on a south border, as the ground is too cold to allow of free germination, and if this is too long about, the seedlings are much weakened. I am not at all particular as to the

MODE OF SOWING. I have had equally good results from sowing in boxes, pots, and in pieces of turf, the turf turned and a drill made to hold the seed. Doubtless 3-inch or 4-inch pots are the best, putting, say, six to nine Peas in each, according to size of pot. Even then, should they appear at all crowded the centre ones should be taken out. Boxes 5 inches to 6 inches deep do well, with boards or slates as dividing lines. From 3 inches to 5 inches space between each will be sufficient. When planting out it is an easy matter to remove one end of the box. The seedlings come out readily with the roots intact, and can be planted out without any injury if done carefully. For sowing in I prefer a good compost, using coarse manure as drainage. In boxes there must be ample drainage. For pots, one good crock will suffice, with plenty of coarse material over it. When turves are used these should be at least 4 inches thick. Moisture must be given sparingly till growth is active. The frames should be kept close at the start,

and the pots or boxes placed close to the glass on a hard coal-ash bottom, and ample covering given in severe weather. Dry Bracken is excellent. Do not cover when the weather is mild, and when the plants are well above the soil ventilate freely in fine weather and give more moisture, but early in the day. Early in March, according to the weather, plant out on warm, rich borders in deep drills. W. F.

POULTRY MANURE.

IN GARDENING ILLUSTRATED recently the value of this was referred to. I think we do not make nearly enough use of the means we have to enrich the soil at a time there is—and will be more so in the future—a scarcity of animal manures. A large poultry-keeper I know and who is also a market gardener finds the above manure of great value, but it is not used at random and is also well prepared, each week being placed in a large heap. Layers of soil are used to cover it when collected, and as it is mostly dug in from November to March the material is then like guano and of great value. I have found it of great value for all the Cabbage tribe. Some Brussels Sprouts planted at the same time as others, but not given any of the manure, are now only half the size. Similar results are found in other cases. Few manures are so valuable when properly prepared. Poultry manure should not be used too freely and should be well incorporated with the second spit. It is then readily taken hold of by the fibrous roots. For surface-dressing I have for years used it mixed with leaf-soil laid up some months before mixing.

Other manures often considered of no value used in this way can be made most useful. By the addition of soot and lime in the case of soils that require them a lasting and not at all costly food is to hand. When we consider the enormous amount of money spent on guano—some of it inferior in quality to the above—it will be seen that we can do much to meet our own wants. In these days poultry-keeping will be a valuable asset to the garden if the best use is made of the manure, which may be increased by a liberal use of dry soil weekly in the runs. F.

REFUSE HEAPS.

Now is the time for dealing with the accumulation of garden refuse, which is usually put into some out-of-the-way corner. It is a good plan to separate the matter, placing all that is in a partly-decomposed condition in one heap, and the remainder, such as hedge trimmings, prunings, cabbage stumps, and the like in another, to be burnt. The latter when so treated are valuable for a variety of purposes if kept dry. The ashes should therefore be placed under cover before rain falls and renders them less valuable. The former, when turned two or three times, may be used in lieu of manure, but as such matter contains myriads of weed seeds and a host of insects lime should be freely mixed with it while the turning is going on. This, combined with the fermentation which usually follows the mixing together of such a variety of refuse, is the means of disposing of both. Where the total quantity of refuse is but small the whole is then best treated by fire. Work of this description can be done when wet weather causes a suspension of ground work in the kitchen garden, as at present. G. P. K.

Lettuces to stand the winter.—A large number of the Hardy Winter White will now be planted at the foot of walls facing

south and west, after the soil has been lightly loosened with a fork. From three to four rows, 9 inches apart, with the same space between the plants, are accommodated in this way, and the plants, especially those nearest the wall, turn in early in the spring and supplement those grown in frames. In former seasons it has been the rule to wait until the fruit-trees have shed their leaves, but as the Lettuces were quite ready for getting out it was adhered to this year. As the variety named always stands the winter without any material damage a good lot will at the same time be planted on a border. The remainder, or the smallest of the plants, will be left in the seed drills to be planted as early as circumstances permit next spring.—G. P. K.

Forcing Asparagus.—Asparagus is easily forced when one has strong, well-grown roots. When I had much forcing of this and other things in hand, part of the garden was given up to the growth and preparation of the plants. A certain portion of land to meet contingencies was trenched and manured every year, and seeds sown in drills 18 inches apart, and the seedlings thinned to become strong. In the course of three or four years it was lifted for forcing, as it was strong enough to produce Grass of good size and quality. The tops were cut down early in autumn for early forcing on specially made hot-beds with tree leaves and stable-manure, the latter being chiefly used to hold the leaves together. The beds, as soon as the frames were on, were made up till the heat rose to 75 degs. or 80 degs. The roots were then packed close together on the bed, and covered with light soil 4 inches deep, and the mats put on again till the Grass was coming through the soil, when the covers were removed and air given to colour the Grass at the same time without lowering the temperature to check growth. Of course, there are other ways of forcing Asparagus. I have forced it when planted thickly in flat baskets or boxes in the Cucumber-house or in other places where the conditions are suitable. The main thing is to have a stock of suitable roots and suitable warmth.—E. H.

Mercury, or Good King Henry.—This is the subject of a note at p. 614. Having grown this largely in Lincolnshire a few words as to its use may not be out of place. It was mostly used as a spring vegetable as soon as the young growth could be had, and to get the best results the leaves must be gathered when quite young. I cut the plants over twice a week. It was cooked in much the same way as Spinach, taking care to reject any old shoots. Used thus there is a total absence of bitterness. It is well when not using the growths to go over the plants occasionally and remove the old shoots. I think its chief value is as a spring or early summer vegetable; at least, growth is more rapid and the produce of better quality at that season.—F. K.

Protecting vegetables from frost.—Care will now have to be taken that Lettuce and Endive which are being preserved in frames are not injured by frost, as where these are of fairly large size decay sets in very rapidly if frost is allowed to reach them. In the case of severe weather the lights should have a thick covering of litter or Bracken placed upon them, and if the frost continues, allow it to remain on until this has passed away. The sides of the frames will also have to have some litter placed around. On the other hand, ventilation will have to be attended to on all fine days. Parsley will also require attention. Once let Parsley become injured by a severe frost or beaten down by snow, decay will rapidly set in. Parsley

must not upon any account be coddled, a free circulation of air being essential during damp or mild weather. Protection from frost and snow and a free circulation of air at other times are what is needed.

French Beans are by no means a profitable vegetable forced in what may be termed mid-winter. Unless the demand must be met, I would not advise sowing seeds till early in the year. On the other hand, with close attention to cultural details and the use of small pots, a small supply may be secured in February. The usual mode of sowing in 7-inch or 8-inch pots is not advisable for this very early crop, as the root-space is too great. The best results are obtained if sown in 6-inch pots, and these will need bottom-heat from the start. A light compost and ample drainage are a necessity. Avoid crowding the plants—three to four plants in each pot being ample. It is best to sow in the fruiting pots, filling the pots nearly to the rim, as later top-dressing is of no value at this season of the year. It is important to use seed of this season's growth, such seed being more vigorous. Grow as near the light as possible, and in a temperature of 65 degs. to 70 degs. Water must be afforded with great care.—F. W. GALLOP.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM DECEMBER 23RD.—*Jasminum nudiflorum*, *Genista hirsuta*, *Erica mediterranea hybrida*, *E. alpina*, *E. carnea* (in variety), the *Cornish Heath*, *Strawberry-tree*, *Daphne Mezereum*, *New Zealand Veroniceas*, *Andromeda floribunda*, *Laurus-tinus*, *Daphne Dauphini*, dwarf *Goose*, *Osmanthus ilicifolius*, *Viburnum rhytidophyllum*, *Winter Heliotrope*, *Hellebore*, *Violet Cress*, *Tufted Pansies*, *Polygala Chamæbuxus purpurea*, *Aubrietias*, and *Polyanthuses*.

WORK OF THE WEEK.—The majority of the Michaelmas Daisies having been replanted in a newly-formed border it was found that a large number of surplus plants was available for naturalising, therefore a few groups were planted by the waterside where others previously planted are doing very well. A mixed lot has been put out on the ridge of an old lane, breaking in among the trees and shrubs wherever possible and forming a loose border to a neighbouring pathway. A start has been made with the digging up of vacant ground among shrubs. It is essential that the vacant spaces required for seeds later on should be well exposed to the weather. Where this is not required it is advisable that the ground should be forked over in order to bury the leaves, and for the good of the shrubs, at the same time improving the appearance of the garden. Any pruning or thinning of shrubs should precede this, in order to avoid the treading of the freshly-turned-up soil. A house used for the storing of vase plants, as well as growing Peaches, has been overhauled, cleaned, and a start made with the pruning and putting into shape of the varied collection of plants. Repotting, staking, and such work will be reserved for wet weather. A start has been made with the pruning of Clematises. Where these handsome climbers are growing on tripods they are thinned out, leaving four or five growths only to a pole, as these are found to be quite sufficient to form a well furnished column. If left too thick, the plants become congested and are not so attractive when in bloom. Where a tripod only has to be furnished, it is an excellent plan, especially with strong plants of the lanuginosa type, to cut the plants down to within 8 inches of the ground level. These will, in spring, throw up strong young

growths, which quickly reach the top of the tripod and fall over, forming beautiful masses of colour. Evergreen species are thinned out carefully, leaving sufficient growth to furnish their supports. The little red Mexican species (*C. coccinea*), which invariably dies to the ground each winter, is cut right down. Another large batch of *Erica mediterranea hybrida* has been planted to extend the Heath garden. Roots of *Tropæolum speciosum* have been planted at the base and on the shady side of Hollies and other shrubs. A few hundred bulbs of *Scilla sibirica alba*, having come to hand, they have been dotted among an existing broad band of the blue form. E. M.

Sussex.

SOUTHERN COUNTIES.

Potatoes for forcing.—As planting will shortly have to be carried out, attention will now be directed to the selection of tubers. Those of medium size are preferred, the varieties being Duke of York and Edinburgh Castle. As Potatoes for forcing always succeed best when forwarded in slight warmth beforehand, the tubers will be placed in seed-boxes and stood in a greenhouse. A little fine soil is first put into the bottom of the boxes, and on this the tubers are stood on end close together, eyes upwards. As each box is filled a little soil is dribbled between the tubers. As the eyes are already on the point of starting it will not be long before they are in fit condition for planting. Not only is it necessary to get the soil in beforehand, but this should be done sufficiently in advance of planting time for it to become warmed through. The compost consists of loam and leaf-mould in equal parts, with some old potting soil added, and the mixture, when the bed inside the frames has been levelled, will be placed thereon about 9 inches to 10 inches deep. The lights will then be put on and the frames kept close until the tubers are ready for planting.

Early Carrots.—As these are in request early in the season an effort is made to produce them as quickly as circumstances permit. Frame culture, with the aid of a hot-bed, is resorted to, and the same kind of compost as that used for Potatoes, with a small quantity of lime rubbish added, is employed. When this has been in the frame long enough to become warm, sowing will take place at once, and until the plants break through the soil the frame will, with the aid of mats thrown over the lights, be kept dark to hasten germination. For this first or early sowing a quickly-maturing Short Horn variety is preferred.

Rhubarb.—After the recent frosts Rhubarb will now force readily outdoors when subjected to the genial heat obtained by the mixing together of a quantity of tree leaves with a little fresh stable manure. Old boxes and barrels with the heads knocked out answer just as well for keeping the fermenting material from coming into contact with the crowns as the proper kind of pots. The bed should be built somewhat higher than whatever is used for covering the crowns with, but openings immediately over the covers must be left so that the latter can be got at readily both when the bed begins to heat and when the Rhubarb is ready for pulling. The materials should be firmly trodden round the pots, etc., as the building of the bed proceeds, and to hold the leaves more readily in place, as well as to conserve heat, the outside should consist largely of stable manure. When fermentation commences the covers should be lifted sufficiently to allow of steam escaping, and a little loose litter cast over them

will, in very cold weather, obviate the risk of the heat being lowered more than is desirable. Unless a great deal of stable manure is made use of in the construction of the bed there is no likelihood of its becoming overheated and the crowns scalded. Such a contingency must therefore be guarded against.

Pea-sticks.—On wet days these should be overhauled, rejecting such as are of no further service and repointing those that can be made to do duty again. The lifetime of Pea-sticks depends on the kind of wood they consist of and the amount of care bestowed on them when not in use. Hazel-boughs form the best support for Peas when they can be had, and if taken care of will last for two seasons. Of Elm, Ash, Hornbeam, and Beech, the two last-named are the most durable and most suitable. Stakes of the first two-named species of wood are seldom of any service the second season.

Bean-sticks.—These, if of Ash or Spanish Chestnut, will serve the same purpose two years in succession. They afterwards come in handy for the making of stakes of different sizes and lengths for the supporting of fruit-trees, etc. An overhauling of the general stock should take place when the haws, owing to inclement weather, cannot get on with outside work, when all that will again be serviceable should be repointed and placed close together in an upright position ready for use. The rejected ones should then be cut up into convenient lengths, and, after pointing them, tied in bundles and stored away in a dry place for future use. The order for any new Pea or Bean sticks that may be required should be given without delay, so that they can be cut and placed on one side while the felling of coppice-wood is going forward.

Young espalier trees.—These, which are as yet, so to speak, in the making, require careful treatment. When the trees are received from the nursery each tier of branches is as near as possible of similar length. To preserve an even balance of growth the same process should be continued until the branches have filled their allotted space. Therefore, when shortening the leading growths situated at the extremities of the existing branches to where the wood is firm and ripe, care should be taken to leave each of a nearly equal length. With regard to the stem portion, which has to be continued in a vertical direction until a sufficient number of tiers of branches has been obtained, this must be cut back to a point just above the wire where the next tier or two horizontal branches are required, and continue in this way until a sufficiency of such branches has been secured. The topmost bud on these cut-back vertical growths, when it breaks, will produce a shoot to extend the stem in an upward direction. The two buds below this will produce shoots which, as they develop, should be utilised for training out, one to the right and the other to the left to form the foundation of the new tier of branches. All shoots which push out below them should be rubbed off. Young wood produced during the past season on the lowermost or existing branches should be cut back to four buds.

Training.—As wired trellises are the usual means employed to support the trees, training simply resolves itself into the tying of the branches and young wood—the latter as straight as possible—to the wires, using fine, soft, tarred twine for the latter and that of a stouter texture for the former. Old ties should be examined every winter, renewing all that are likely to cut into the bark before another season comes round.

Bedding plants.—These require looking to occasionally, when dead or decaying leaves, etc., should be removed. Calceolarias, Pentstemons, and other subjects in frames also require picking over now and again, especially after frost, as the leaves are apt to damp, while the severity of the weather precludes the possibility of admitting air for days together.

Cucumber seed.—Where winter Cucumbers are not grown, and the fruit is in request as early in the year as it is possible to produce it, it is an advantage, if the house is not yet at liberty, to sow seed at the present time and grow the resulting plants on in a stove until they become established in 7-inch pots. Then if transferred and planted out in the house intended for them they will come into bearing much earlier than if sowing is deferred until near the time the structure can be made ready for them. The seeds are best sown singly in small pots filled with light, rich material, as this obviates the necessity for disturbing the roots, as is the case when several plants are raised in the same pot. A propagating-frame is a suitable place in which to raise the plants.

A. W.

MIDLAND COUNTIES.

Hardy fruit.—The pruning and training of hardy fruit-trees should be completed as soon as possible. The planting of fruit-trees has been delayed, owing to heavy rains, 5.30 inches of rain having fallen within the last six weeks. In replacing old wall-trees the old soil to a depth of about 18 inches and 4 feet wide is entirely removed. If the sub-soil is wet and cold, measures must be taken to provide drainage by using broken bricks, covering these with a layer of lime rubble. Cover the drainage material with turves, Grass-side downwards, and fill in with good, roughly-chopped loam; or, failing this, good garden soil, adding lime rubble and charred refuse to heavy soils, especially when planting stone fruits. No manure should be used at the time of planting. Any extra care bestowed at the time of planting will be well repaid later by fruitful trees. Prune all damaged roots and any that are extra long. Place the tree in position and spread out the roots carefully at varying depths, working in amongst them some of the finer soil and making the whole firm as the work proceeds. The topmost roots should not be more than 4 inches below the surface when planting is completed. In planting standard and pyramid trees on heavy and wet ground it is necessary to provide drainage, and the soil should be well broken up. All freshly-planted trees should be staked and a permanent label attached to each. Mulch the trees with some litter or other suitable material, but do not employ animal manure.

Fruit-room.—Examine carefully all Apples and Pears, and remove any which show the least signs of decay. If any are found to have decayed so badly as to cause a damp spot on the staging see that it is made thoroughly dry before placing more fruit thereon.

Perpetual-flowering Carnations.—In the Midlands and further north the main batch of Carnation cuttings should not be struck later than the month of January, and the sooner they are in the better. A good way to strike them is in an ordinary cutting-box filled with silver sand which has been previously washed. Place the box in a house with a bottom-heat of about 60 degs. and an atmospheric temperature of 55 degs. Care should be taken that the cuttings are free from red spider. A good plan is to put the cuttings into a tank of cold water for the night, and next morning insert them in the sand with an

ordinary dibber, afterwards watering them with warm water applied through a rose-can. Repeat the warm water daily for about eight days; after that period spray with a syringe overhead in the ordinary way until the cuttings are rooted, which at this time of the year will take from twelve days to fourteen days. When well rooted pot off singly into very small pots, using a light, sandy compost. The plants of

Euphorbia pulcherrima (Poinsettia) which have finished flowering should be encouraged to ripen their stems by gradually decreasing the amount of moisture at the roots. When all the foliage has fallen and growth is dormant they should be placed in their resting quarters. Examine them occasionally to see that the bark is not shrivelling.

Begonia Gloire de Lorraine.—Plants which have finished flowering will provide a supply of early cuttings, which usually produce the best specimens. Select the finest plants for stock and cut back the old flower-stems, retaining a fair amount of foliage. Afterwards place the plants in a structure having an atmospheric temperature of about 55 degs., arranging them near to the glass. Keep the plants moderately dry until the new shoots appear. Plants of this Begonia and its varieties may be propagated from leaves, but I prefer basal shoots.

Forcing.—To maintain a continuous supply of bulbous and other forced flowers it is necessary to place a fresh batch of plants in heat every week. Azalea mollis, Lilacs, Viburnums, Wistarias, etc., may now be forced with satisfactory results.

Flower garden.—Vacant portions should be thoroughly broken up, leaving the surface as rough as possible, that a good tilth may be obtained when the time arrives for sowing or planting. Deep cultivation is as necessary in the flower garden as it is in the vegetable garden. Therefore turn up the ground to a good depth either by trenching or deep digging, and work in a liberal quantity of rotten manure where the ground is poor, giving the surface a good dressing of soot as the work proceeds. The soot will have stimulating properties and prove a valuable agent in cleansing the ground. These remarks specially apply to those quarters intended for such as Delphiniums, Pentstemons, Phloxes, Sweet Peas, and other summer-flowering plants that require rich soil and a deep-rooting medium. If these conditions are provided and a good mulching given the plants they will the better withstand drought. In some instances there are beds which have to be used for similar plants year after year, and therefore become partially worn out. In this case the old soil should be taken out to a depth of at least 2 feet and some fresh manure placed in the bottom, refilling the bed with fresh soil. If available the best soil for filling the bed is loam cut from an old pasture and stacked for twelve months before use. If the loam is of a fairly fibrous nature little else will be required during the first season, but if of a heavy, tenacious character some well-decayed vegetable matter or leaf-soil and coarse sand should be added to lighten it. Make the soil firm in the trench and place sufficient so that it will be fairly level when it has settled. This work should not be done in wet weather.

Planting shrubs.—Every opportunity should now be taken to carry out any planting that is contemplated. In preparing the ground for trees and shrubs it should either be trenched or dug deeply. Shrubs should be selected not only for their flowers, but for their autumn-tinted

foliage and their coloured bark, which brighten up the landscape when the plants are bare in winter.

Hotbeds.—It is necessary in many gardens to augment these considerably during the present month, as there are many choice vegetables which can be brought forward with the aid of hotbeds and portable frames. They are invaluable to the gardener who has to supply large quantities of forced vegetables. Not only are frames of use during the spring, but they can be utilised with advantage every day in the year, and with the aid of freshly-fallen leaves much less expense is incurred in providing the requisite heat. The chief danger in hotbeds lies in getting too much heat, and before adding the soil one must be quite sure that the heat is on the decline, for if once the soil becomes baked (as it most assuredly will if the heat is excessive) no crops will grow in it satisfactorily. Asparagus, Carrots, Turnips, Radishes, Potatoes, and such crops are all suitable to this kind of treatment.

Carrots.—Late sowings made either in heated pits or on hotbeds, for supplying young roots early in the year, should be thinned sufficiently to prevent the young plants becoming drawn. The soil should be stirred between the rows and air admitted to the frame whenever the weather is mild. On bright days syringe the plants and close at 1 p.m.

Cauliflowers.—If the stock of autumn Cauliflowers is short a sowing of some early variety should be made about the middle of January. Raise the plants on a hotbed. If the young plants are pricked off as soon as they show their second leaf, and liberally treated, they will be ready for planting out on a south border early in April.

Tomatoes sown at the end of October are now good, strong, sturdy plants, ready for shifting on into 6-inch pots. The pots must be well drained and the soil should be moderately light and porous. Do not pot too firmly. The soil should be nicely warmed and great care taken not to give the plants a check. It is advisable to pot them in the house in which they are growing. Do not over-water, rather err on the side of dryness at this time of the year. Keep them in a temperature of about 60 degs., and as close to the glass as possible. F. W. GALLOP.

SCOTLAND.

Current Work.—During the week outside work has been entirely stopped by wintry weather. A heavy fall of snow was followed by a brief but severe frost, which, in turn, gave way to heavy rain, which lasted until almost the end of the week. It is worthy of note that the snow-fall experienced in this locality since November 11th is already greater than the aggregate fall for the winters of 1913-14 and 1914-15 combined. In addition, too, the separate falls have lain over longer periods, and the frosts which followed were more intense than usually experienced. When conditions were at all favourable during the week, progress was made with the carting away of leaves, which had been previously collected in heaps at suitable places. A portion of these is kept in the neighbourhood of the garden, the remainder being put where they are out of sight. The older collections of leaves, now half or wholly decayed, were turned over in order to make room for the freshly-gathered ones, and in order that when time and weather permit some leaf-mould may, after having been sifted, be got under cover in anticipation of the spring repotting. The manure-heap was also re-turned and tidied up. Returning always helps in the process of de-

composition, and any accumulations of turf-parings, wood-ashes, and similar things, if added during the re-turning, always add to the manurial value of the material. Label-making occupied some time during the stormy weather. Many prefer to buy their labels ready for use, but when special sizes are needed it is better to make them during the winter months at spare times. For this purpose I find nothing better than plasterers' laths, which are inexpensive, easily smoothed, and can be cut to any required length without waste. After being made the various sizes are collected, painted, and bundled

crocks sifted and sized; in fact, the odds and ends of work which accumulate in the potting-shed in favourable weather for outside work were put to rights.

Boilers and flues.—In the course of the week advantage was taken of a sunny forenoon to overhaul flues, valves, and hot-water apparatus generally. No matter how carefully flues may be cleaned every week there is always a gain in looking over them in a thorough way periodically. As a rule this inspection is undertaken twice a year, at about six-monthly intervals. In the present case a furnace which had not been giving satisfaction was

think, the same tendency as there was at one time to rush cuttings in at the earliest date possible. At the same time, when good and firm shoots are obtainable, it is just as well to utilise them. A mellow, sandy compost suits them perfectly, and on the top of each pot about a $\frac{1}{4}$ inch of sharp sand is allowed. Opinions differ as to the temperature which is best suited to the needs of Chrysanthemums in the cutting stage. Personally, I incline to the belief that they emit roots more quickly when given a heat of 50 degs., or even a trifle over, but care is essential in watering. As soon as roots are formed a slightly cooler atmosphere will render the growth of the young plants more sturdy and afford less opportunity for insect pests to do damage. In the case of varieties grown for cutting or decoration the cuttings are put thickly into 5-inch pots; but when specimens are required for special purposes it is better to put them singly into thumbs, so that there may be no disturbance of the roots when the plants are ready for potting. I like, when possible, to keep the cutting pots on a shelf near the light. There is not often excessive sunshine at this time of the year, but should the cuttings show signs of flagging a dewing over with the syringe will soon freshen them up.

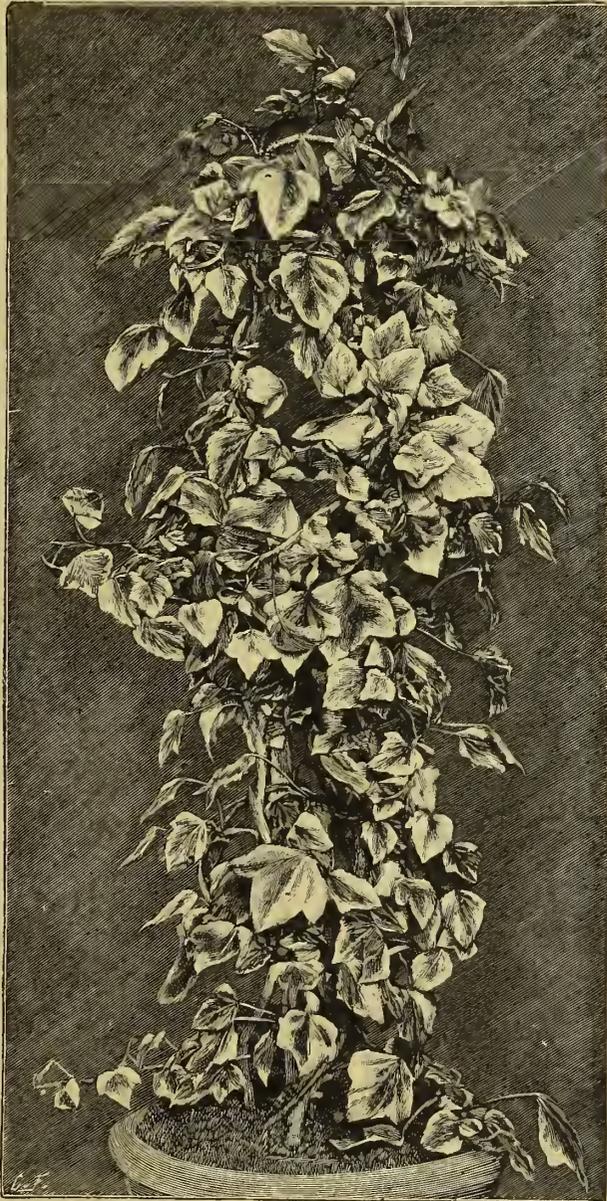

Adiantums—chiefly *A. cucuatum* and *A. gracillimum* which were cut over in late autumn—are again well furnished, and, with Asparagus, provide fronds for cutting. Fireheat is being kept as moderate as possible.

Malmaison Carnations.—Advantage was taken of the stormy weather to look over and clean down some Malmaison Carnations. These are two-year-old plants—that is, they bore a single bloom last spring, and were potted on into 8-inch pots afterwards. In a short time these will spindle for flowering, and will prove useful. Having been grown in a comparatively low temperature the plants are clean and thrifty, no signs of rust being, as yet, visible. I think it is now generally accepted that rust is induced, if not caused, by coddling Carnations in their younger stages, and as rust is highly infectious, the less fire-heat the plants receive the more likely are they to escape infection. Newly-received plants ought always to be closely inspected, and, when it is possible, to be quarantined for a time. Plants may appear to be perfectly clean when they arrive, and yet may develop rust, or something equally undesirable, very shortly afterwards. Meantime, only sufficient moisture to maintain the plants in a healthy condition is given; indeed, to a casual observer it might appear that they were altogether too dry.

Stove.—The latest addition to the flowering plants in the stove is the blue Coleus thyrsoideus, which, if for no other reason, is very desirable at this time for its cobalt-blue sprays. It is generally recommended that this plant be not pinched back after the end of August. In order to test this, half-a-dozen stout, well-grown plants, carrying from six to eight shoots, were pinched back on September 28. The result fully justifies the recommendation. The shoots broke well enough, but the growth is weak, spindly, and altogether inferior, while the symmetry of the plants has been spoiled. They will, by and bye, be cut back and used for the production of cuttings. Other flowering plants continue to be effective, and show no sign of deterioration. Over-crowding is a fault most of us find difficult to avoid, but presently it will be rectified. A light vaporising was given in the course of the week.

W. MCGUFFOG.

Balmie Gardens, Kirkcudbright.

An Ivy in a pot.

in readiness for use. Of course, these home-made labels are merely for general purposes—pot-plants, seed-beds, Beans, Peas, Onions, in fact for stuff of annual duration. A better type of label of more enduring wood, and carpenter-made, is used for perennial and special plants. A little net-mending was also done. This is interesting work if a little tedious in the case of large nets. At any rate it is always much better to do such repairs as can be effected at this time, for much loss of time and worry are frequently experienced just when the nets are needed if they are found to be badly holed. All dirty pots were washed up and graded,

found to have a flue partly obstructed by a piece of brick which, owing to the mortar becoming brittle, had fallen, and which had lodged just out of reach of the flue-rake. This being taken out the full draught was restored and the heat is now raised in a quick and satisfactory way. This illustrates the advantage of these periodical inspections, and as clean flues and good heating go together it is just as well to see that everything is right, with fuel at its present price and with a prospect of further increase.

Chrysanthemum cuttings.—During the week a few cuttings of various Chrysanthemums were put in. There is not now, I

BOOKS.

"CORNERS OF GRAY OLD GARDENS."*

This is a curious little book with a rather affected title and drawings in colour by Miss Margaret Wakefield, far better done than most of the colour work of the day. The rest of the book is made up of reprint matter that has already appeared so far back as Sir Walter Scott and so late as Mr. Le Gallienne. The article on old-fashioned gardening is really a copy of Parkinson, which most of us have already read. There is not much difficulty in book-making of this sort, but, on the whole, the result is a handy and pretty little book, though disfigured by a binding the most vulgar in design I have seen so far. It would scare the birds from a cornfield if only large enough. W.

"LES PALMIERS DE LA COTE D'AZUR."†

As Palms are seen in our country we get little satisfaction from them. The place where they show their real dignity and grace is perhaps the South of France, where in some of the little valleys or in warm gardens it is amazing how well they will do. This book is very well done, and the printing is good, and not on the elayed paper of the day, but as regards the subject we distinctly think that such things as Palms are better omitted from the garden, even if we succeed in growing a feeble specimen here and there. Such things never consort properly with our own vegetation.

LAW AND CUSTOM.

Dispute about hedge (J. W.).—It is not easy to advise fully on this without being on the spot. To begin with, your tenant is bound to let you enter the premises for a reasonable purpose, but we think you are wise to hang the matter up until you are rid of him. Then you will be quite justified in properly cutting the hedge and the saplings down to the level of the hedge. In view of what has occurred we think you would be wise not to make any further approach either towards the adjoining tenant or his landlord. Maintain firmly your right. That is your only line in a case like this. With regard to the Plum trees everything depends upon whether they are on your land or on the land of the neighbouring owner. It is probable that strictly your land extends beyond the roots of your hedge, because when a man plants a hedge he digs a ditch at the extreme limit of his land, throws the soil inside, and plants the hedge on the bank thus formed, so that if there is a ditch on either side of your hedge that would belong to you, and if the Plum trees are within the furthest line of that ditch the presumption is that they would be yours. We think, however, that the safe course to adopt is to assume that your wall is your boundary line, and to continue an imaginary line from that and treat this imaginary line as your boundary. If the Plum trees are outside that on your neighbour's side treat them as his, and do not interfere with them except to this extent, that you may cut off any portions of them that overhang on your side the imaginary line suggested. Of course, the hedge being your hedge, you are entitled to cut that on both sides, and may for that purpose enter on your

neighbour's land, subject to this, that you must not do any avoidable damage to his land in doing so.—F.

Trespassing cats (G. J. B.).—Your only practical remedy is to chase them out or erect wire netting in such a way that they cannot enter your garden. If the cats do actual damage, and you request your neighbours to prevent a recurrence of the trespass and they ignore your request, you may, on proof of the facts, recover damages in the County Court.

CORRESPONDENCE.

Questions.—*Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly written on one side of the paper only, and addressed to the EDITOR of GARDENING, 63, Lincoln's Inn Fields, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, the name and address being added to each. As GARDENING has to be sent to press some days in advance of date, queries cannot always be replied to in the issue immediately following their receipt. We do not reply to queries by post.*

Naming plants.—*All who wish their plants to be rightly named should send fair examples of each—the stem, leaf, flower, or fruit. (Snippets of leaves and points of shoots are useless.) Not more than four plants should be sent in any one week by the same correspondent. Where more than one kind is sent they should be numbered. Of conifers the fruit should always be sent.*

Naming fruit.—*Several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. We can undertake to name only four varieties at a time.*

PLANTS AND FLOWERS.

Tropæolum tuberosum not flowering (S. B.).—The abundance of foliage and absence of bloom indicate over-luxuriance of growth, due to excessive richness of the soil. We should try it another year, when the soil will, to some extent, have become exhausted, and you will probably be rewarded with bloom.

Culture of the blue Cornflower (E. Y.).—The blue Cornflower is a hardy annual which sows itself in autumn and grows well all the winter. It may be sown from gathered seed at any time during the autumn or early spring—autumn being best, as the plants will be stronger. Seed is offered in nearly all catalogues; its botanical name is *Centaurea Cyanus*. It is grown in large quantities for the London and other markets.

Plants for small conservatory (J. Arthur).—During the summer your house may be kept gay with ordinary flowering subjects, as Fuchsias, Heliotropes, Lantanas, Calceolarias, Begonias (tuberous-rooted), Pelargoniums of various sorts, etc. In the autumn you can have Chrysanthemums and Lilliums. A few hardy Ferns may also be included, as also a few of the hardier Palms. When you have gained experience you may increase the list, but do not overcrowd in any way.

Cestrum aurantiacum (C.).—For training on pillars or rafters of a greenhouse this fine climber is exceedingly well adapted. It is an autumn-flowering plant, and one of the simplest culture. It should be planted out in a bed of rich, well-drained soil, and be cut hard back in spring. Thus treated, it will not fail to produce every autumn a profusion of rich golden blossoms in long, drooping terminal bunches, which contrast finely with the deep-green foliage.

Vallota purpurea (A. B.).—Potting should be done as soon as flowering is over, giving a compost of three parts rich loam and one part well-rotted cow manure, leaf-mould, and coarse sand. The plants should be given a light place in a warm greenhouse and kept steadily growing, but until February very little water will be required. As the days grow longer more moisture will be required, and from June till they throw up the flower-stems a cool pit facing south will answer well for them. A mistake is often made in drying off the bulbs in winter, this doing much harm, and is almost certain to prevent the bulbs flowering the following year.

Poinsettias losing their leaves (Grower).—This useful winter plant has an inveterate tendency to lose its leaves before the flower bracts are fully developed. Probably the plants have become root-bound, or they have

been placed too closely to each other. They require good soil to grow in, and had better not be planted into their flowering pots until the end of July or early in August. They should also be kept in a well-aired house, or even out-of-doors during the summer months; and in winter a temperature of 55 degs. to 60 degs. would suit them better than one of 50 degs. But however well they are grown in other respects, if they are too much crowded together, or crushed in amongst other plants, the stem-leaves will drop off.

Pruning Clematisses (J. Arthur).—The lammigosa section (to which the variety Lord C. Neville belongs) must be pruned in February or March. This consists in removing the weak and overcrowded shoots. As the Clematisses belonging to this set flower on the old or ripened wood, the strong one-year-old shoots should be nailed in as far as they have become well ripened, cutting away the sappy points. Train the shoots that may be left in such a way that all vacant spaces are filled up. The varieties belonging to the C. Jackmani set flower on the young or summer shoots. The old growths in this case are cut back each season, as soon as the frosts have disfigured the plants, to within about 6 inches of the soil. In order to encourage a vigorous growth mulch the plants with rotten manure when growth is well on the move.

MISCELLANEOUS.

A poor lawn (Wm. Brooke).—From what you say, we should fancy that the soil is in a very impoverished condition. In such case the only remedy is to have the lawn remade. Dig it deeply, and as this is being done incorporate plenty of rotten manure and carefully pick out all the bad weeds. If you can procure good turf, then have it laid in the early spring. If you cannot get good turf, then have it sown down in April after the soil has been carefully levelled and made firm. The only way to get rid of Plantains, Daisies, etc., is to spud them out, afterwards applying a dressing of rotten manure, loam, and wood ashes, letting this lie during the winter and then working it into the soil. In the spring apply sulphate of ammonia, at the rate of 3 lb. per square rod, so as to encourage the growth of the various Grasses. Basic slag is also very good, applying this at once, if its effect is to be noticeable next summer, as it is very slow of action. If the Grass is very weak, then you may apply the basic slag at the rate of 5 lb. per square rod, giving in the spring a further dressing of nitrate of soda or sulphate of ammonia at the rate of 3 lb. per square rod. In any case you must first get rid of the weeds.

SHORT REPLIES.

Rev. E. Hackett.—Kindly send a specimen of the Apple to which you refer, and we will do our best to help you.

NAMES OF PLANTS AND FRUITS.

Names of plants.—*F. G. Lyne.*—We cannot undertake to name *Horist* flowers.

Names of fruits.—*Miss Strong.*—Pear *Beurré Hardy.*—*F. I.*—Impossible to name with any certainty from the poor specimens you send us.—*A. R. C.*—Your Pears are *Glou Morcean* and *Josephine de Malines*, but as you have not numbered them it is impossible for us to specify which is which.

Admission to Kew Gardens.—We learn that on and after New Year's Day the following fees will be charged:—On Monday, Wednesday, Thursday, Saturday, and Sunday, 1d.; on Tuesday and Friday (students' days), 6d. The admission of photographic apparatus, 3d. Bath chairs will be permitted to enter the gardens during public hours when the condition of the paths is suitable, on payment of 1s. on students' days and 6d. on other days. On written application to the director by students and artists, season tickets will be issued on payment of a fee of 5s. These permits will cover free entrance on students' days and before public hours on other week days. On payment of a fee of £1 season tickets can be obtained on written application to the director. These tickets will cover admission on any day during public hours.

PRUNING CLEMATIS.

I was interested in the note on Clematises at Nuneham in the issue of January 1st (p. 1), having the same kind (Nellie Moser) in different positions—on a wall, on tripods, and on a pergola, and have a fair result in all these cases. The best effect I have is from a plant growing on a Chinese Lily Tree (Magnolia Yulan). I planted it at the base of the tree some years ago and forgot it. Forgetting about things is a useful aid to picturesque gardening. In flower it looks out at one with the beautiful foliage of the tree all round it, and it prunes itself. No one touches it, and it may be the rich foliage of the tree keeps it within bounds. While telling of this I may as well speak of a few other experiences I have had in pruning, or rather not pruning, Clematises.

In putting a fence round an orchard many years ago I threw some seeds of the European Virgin's Bower (*C. viticella*) into the fresh-dug bank and forgot them, and now, every year, the plants come up and throw a delicate foam of flowers over the fence, which is a live fence—the only one proper to the work. Every ten years or so the fence is cut down without any harm to the Clematis. The Indian Mountain Clematis (*C. montana*), when it climbs up an Oak or a Pine to a height of 40 feet, does not want pruning—indeed, could not well be pruned, though I dare say if one believed all that is told about pruning in books one might make the flowers a little larger with pruning. But they are large enough as they are. This beautiful climber needs no care of any kind, as it runs over house or tree, and spreads itself everywhere. I put it on Apple-trees and it really was too much for them. They looked in flower like fishing-boats with white sails, and I had to give way!

The kinds that flower on the islands of the Mediterranean do not want, or get, pruning, and they do very well. So with the yellow-flowered *C. tangutica* and *C. orientalis*, which never look so pretty as when one neglects them.

Anyone who has seen the Clematis wild on our own chalk hills will not need to be told that it is the most vigorous and hungry climber that exists. In some parts of the Home Counties the men call it Devil's Guts, and this Saxon name for it was no doubt devised after some vain attempts to get rid of it. So all the kinds of Europe that one sees are vigorous climbers, and I say trust them in that way

when you can. See the way they seed, so freely that one can get the seed of the wild kind for a few pence. They can also be naturalised in copses or shrubberies, or on fences, by sowing the seeds on a bit of broken, bare, or recently-burnt ground. Throw the seed on and kick it in. I have had some failures, I may say, from seed thrown where there was a covert of rough Grass, as that prevented the seed from taking hold of the ground.

Think of the vigour of the wild kinds of Clematis we may see. On the north Downs the native kind is more vigorous than the stoniest Briars; my mountain Clematis on Oak, Yew, and Pine-trees, 30 feet or more high. Such Lianas, as we may name them, prove to us the natural habit of the wild species, and they are easily increased by seeds or layers; yet we may see in nurseries men propagating them by grafting one thing on the other with disastrous results, as one may see in gardens. The grafting as carried out reminds one more of a physiologist joining nerves together in some animal's flesh, and it is a short-sighted plan on the part of nurserymen to allow this footling when increase is so easy by layers and seeds.

W.

NOTES OF THE WEEK.

The Winter Heliotrope.—"W. McG." is not kind or just to the Winter Heliotrope. He has no business to speak of it in a garden at all. It is a plant for a rough, sandy, or gravelly bank, and will not flower in good or ordinary soil; but put it on a cinder heap or poor piece of railway bank and it will flower beautifully in winter. No one has any need to put it in garden soil. It is a charming plant, and as I write I have a large bowl of it before me, where it has been for the last ten days. It is the best mid-winter plant we have and deserves no abuse.—W.

Trees and shrubs in storm.—These have always had a charm for me, and in the gale of New Year's Day I enjoyed them to the full. Cedar of Lebanon, old Scotch Fir, and trees of Yew of natural form and growth are lovely in storm. Among the shrubs beautiful in storm, the evergreen Oleasters (*Eleagnus*) are handsome, the silvery-leaved and the large-leaved the best in our country so far—fine evergreens at all seasons. When the shoots are tossed by storm we see silvery and old gold colours at their best. They are as yet little planted considering their

merits, and that it is only in our own time Mariés introduced the fine *E. macrophylla* from Japan.—W.

Roez's Lily.—Sir Herbert Maxwell, writing in *Country Life*, says this is easy to grow. It is, he says, "one of the innumerable varieties of the Panther Lily (*L. pardalimum*). The flowers, which are most liberally produced, are of a beautiful light orange colour with claret spots. All the Panther Lilies grow from rhizomes instead of bulbs; but Roez's Lily does not spread in the free manner of the others, and must be propagated from seeds or scales. Like its congeners, it is a lover of a moist, indeed a boggy, soil, relishing peat, sand, and leaf-mould, and abhorring lime."

Storing Apples.—I think a good deal of unnecessary fuss is made over storing Apples, as they are put on dry, arid shelves, and lose their rich juices far sooner than they ought to do. I frequently pick up beautiful, sound fruits in the orchard that have lain all the winter exposed to rains, etc., with only a covering of leaves and Grass, yet they are invariably more juicy than those stored on shelves. I think we might take the hint and store our late-keeping sorts of fruit in cool quarters, where the moisture arising from the soil will keep them from shrivelling, for it is useless blaming the varieties for their non-keeping properties, if we do not treat them rationally.—T. P.

Root-pruning.—I dissent quite from "E. H.," on page 2 of GARDENING ILLUSTRATED, January 1st. My soil in which I grow the standard Pear is as stiff and cold as any in Britain. All this footling about root-pruning comes from confining the tree in small forms, which require very constant and careful pruning. It is often forgotten that the Pear is a forest tree, and a much bigger forest tree than the wild Apple. The attempts to confine it to small forms are against Nature and must be paid for. The ceaseless and elaborate pruning of the dwarf tree is against its fertility, half of it really preventing the tree fruiting at all. Let the tree grow in its natural way, thin out the branches, and do not cut back the main shoots, and you will get a much better return.—W.

Mrs. Wilson's Barberry (*Berberis Wilsonae*).—Of the numerous Barberries that have been introduced from China within recent years this is one of the best. It is a low-growing species of graceful habit,

whose thin branches are more or less spiny. The flowers are small, pale yellow, and not particularly showy, but the roundish coral-coloured berries, borne in great profusion, are of a somewhat translucent character, and are seen to advantage when in an elevated position so that the sun shines through the bushes. For this reason, and also owing to the fact that it is of neat growth and in no way of an aggressive character, this Barberry is particularly suitable for planting as a rockwork shrub. Some individuals are quite deciduous, while others are sub-evergreen in character. Seedlings can be easily raised, but there is at times a certain amount of variability about them.—K. R. W.

Calceolaria deflexa.—This pretty, winter-flowering species of *Calceolaria* is also known by the name of *C. fuchsiaefolia*. It is of a neat, freely-branched habit of growth—in fact, quite a little shrub. The flowers are of a rich yellow colour. Attention was first directed towards it during the late seventies of the last century, and for a time it was largely grown. It is now, however, not often met with, one probable reason being that it is rather more particular in its cultural requirements than some of the *Calceolarias*. Like many other Chilean plants, it is seen at its best in districts where the atmosphere is fairly humid. This *Calceolaria* is interesting as being one of the reputed parents of *C. Burbidgei*, a hybrid now extensively grown. This hybrid was raised by the late Mr. F. W. Burbidge, at the Trinity College Botanic Gardens, Dublin. He always regarded it as a cross between *C. deflexa* and the somewhat coarse-growing *C. Pavoni*. Judging by appearances, there is no doubt about *C. Pavoni* being one parent, but it has been suggested that *C. amplexicaulis* was the other.—W. T.

The hardy Heaths in winter.—Those who grow hardy Heaths to any extent and who take great pains to see that they receive their annual shearing immediately their flowering period is over do not realise the beauty which is sacrificed by this practice. During the rough and stormy weather of the past six weeks no part has been so pretty as the Heath garden, where the plants have been allowed to develop naturally and display their charming soft grey-brown seed-vessels sprinkled here and there with a few late blossoms. This especially holds good with the Cornish Heath and its varieties, the Dorset Heath, various forms of the common Ling, among which is the Copper Heath, a fascinating variety which, under the sun's influence, assumes a charming crimson tint at the tips of its branches. The *Menziesias*, too, are very attractive when left in this way, and take on pretty tints. With the turn of the year these plants are visited by scores of bullfinches and the little blue-grey titmouse in search of the seeds, for which they appear to have a special liking. Groups of the fresh young *Asparagus-green* growths—laden with buds—of the Portuguese and Southern Heaths are beautiful at this season of the year. Beautiful, too, are those just bursting into bloom, of which *Erica mediterranea hybrida* is an easy first. This delightful variety is partly open and will shortly be a mass of colour. Rapidly opening, too, are *Erica alpina* and the various forms of the alpine Forest Heath (*E. carnea*), including its charming white variety which is usually a little in advance of the type. Where these hardy Heaths are used for edgings to other subjects the winter effects are missing, as it is only by extensive grouping that such are obtained.—E. MARKHAM.

VEGETABLES.

WINTER TOMATOES.

I HAVE noticed that the Tomatoes grown especially for the summer and early autumn supply have given a lighter crop than usual. At any rate, so far as I have seen, there were fewer home-grown Tomatoes in October and November than usual. The excessive rainfall in many parts of the country may in a great measure account for slow ripening, owing to lack of sunshine. This applies with equal force to plants grown under glass. In cold-houses the crop was later than usual, and the fruits ripened slowly in consequence of the above cause, and again the early frosts also greatly influenced them. For many years I endeavoured to have home-grown ripe Tomatoes all the year round if possible. With small houses, and sufficient heat at command, it was possible, by careful culture, to have Tomatoes, say from January to April. For years I relied upon cuttings struck late in the summer, one cutting in a 60-pot, and grown quite close to the glass to get them as sturdy as possible from the start, only giving a 6-inch or 7-inch pot for fruiting. For winter work good loamy soil was necessary, with ample room left at the final potting for feeding when a good set was secured. Those who have grown Tomatoes from cuttings well know how soon the plants commence to show blossom. I admit the yield cannot compare with that of the summer fruiters, but, on the other hand, when the number of plants that can be grown in a small, close house is taken into account, the crop for home supplies should not be despised.

For many years for this work I grew Conqueror and Large Red, but neither of these can compare with Winter Beauty as regards shape and quality. The Large Red is often of poor shape, but it is a reliable cropper grown as advised. To be a success the plants must set their fruits before the dark days. At no time, no matter what variety is grown, should there be too much heat; indeed, in mild weather I found it advisable to always have a little space open at the top ventilators. White-fly, one of the worst pests of winter plants, is readily destroyed by fumigating before it gets much headway. Of course, no one would now think of growing Conqueror for winter work, but it had its merits. It was a very early setter, made less useless growth than the other variety named, and though the fruits were not large—indeed, many under medium size—they were liked for winter salads. With Winter Beauty there is no need of so much preparation in the way of propagation from cuttings. Excellent results can be obtained by sowing seed in August or even a little earlier. The seedlings should be grown as hardy as possible at the start. I found cold frames best. On warm nights the glass was removed to secure sturdy plants. The seedlings must be potted on early and kept close for a time, and even with this variety for winter supplies I would not give a larger fruiting pot than advised above. The fruits are of fair size and splendid colour, and set freely in the autumn. Provided good plants are secured, grown as hardy as possible at the start, and with no delay in getting them into their fruiting pots, it will be found that Winter Beauty can be grown to advantage for winter fruiting. Grown as advised, fruits will have set freely by the end of October, when the plants should be placed in their winter quarters.

W. F.

NOTES AND REPLIES.

Treatment of peat.—Owing to scarcity of manure through the advent of motors I have had to look elsewhere for a substitute, and find that within a short distance of the gardens there are millions of tons of peat for the getting. How can I treat this, so as to get the best out of it, and what influence would lime or basic slag have on it, and what elements would be liberated for the successful culture of vegetables? The soil here is gravelly, so the addition of peat would help in retaining the moisture and improve the texture.—LUCKY HALFPENNY.

[As you remark, the adding of a certain amount of peat to your gravelly soil would act beneficially by rendering it more conservative of moisture, but you must be careful not to overdo it or you will make the staple too light and thus defeat the object in view. With regard to its employment in the place of manure, it must be fortified with some artificial to render it effective, and to correct the sourness that is present in most kinds of peat a certain amount of lime should also be added. Therefore, to each ton of peat $\frac{1}{2}$ ton of lime and 1 cwt. of bone-meal should be added, and mixed intimately with it. The way we recommend you to use it is to spread it on the surface of the soil as thickly as you would do if you were using manure. The mixture should be incorporated with the staple without delay, and the earlier it is applied the more satisfactory should the after results be.]

Turnip Golden Ball.—We rarely see this excellent winter Turnip on sale or much grown in the south; indeed, I may go farther and say in many parts of England, excepting the north. There is no lack of variety even in the yellow-fleshed Turnips, but, in my opinion, the one noted above is the best garden form for winter work. A good sample should have a rich golden colour and not be at all coarse. I think roots the size of a cricket-ball just the size for home use, and there is no waste. The quality, too, is excellent. This variety being a quick grower, need not be sown too early. July is quite early enough; indeed, in the south I prefer August. One need not be afraid of a few degrees of frost, as this is one of the hardiest Turnips grown and one of the best keepers. Readers in Scotland will think southern growers peculiar in not growing such an excellent winter vegetable. Many object to the colour when cooked, but I think Golden Ball has no equal as regards flavour, while its excellent keeping properties should make it a favourite, as, given cool storage, it may be had quite sound till the early spring-sown Turnips are ready.—C. R.

Tomato notes.—This, on the whole, has been a paying crop under glass this year. There is a tendency to build very large houses for Tomatoes, but as far as I have seen the best crops have been grown in houses of moderate size. My best crops have been grown in houses 100 feet long, about 12 feet or 15 feet wide, and well ventilated. The plants along each side were trained under the glass till they met under the roof in the centre. I have tried many kinds, but can find nothing better than a good selection of Sunrise. All things have a tendency to wear out, but with care in selection and as the seeds will retain their reliability more than one year, there should be no difficulty in the matter. Where the cool houses are filled with *Chrysanthemums* after Tomatoes the soil is not so suitable for Tomatoes the following year. This I have noticed repeatedly. Tomatoes do best in firm ground both indoors and outside. Where the borders are used for plants in pots and a sprinkling of ashes added the latter are an advantage rather than otherwise to the Tomato crop.—E. H.

TREES AND SHRUBS.

JAMESIA AMERICANA.

This, native of Western North America, has been grown in English gardens since 1862, and was originally discovered about twenty years before. It is not very much like other shrubby members of the Saxifrage family in general appearance, and is quite distinct amongst hardy shrubs. Of dense habit, it is usually met with as a shapely bush 3 feet to 4 feet high, although it sometimes grows twice as tall. The leaves are coarsely toothed, and are covered with greyish hairs, especially on the underside. The white flowers are produced in May in upright panicles, and most closely resemble those of *Deutzia*. When in full flower it is a very attractive shrub. It can be increased by seeds, cuttings, or layers, and grows well in moderately light, loamy soil. A position exposed to sun is, however, essential to success. As it is apt to become a dense thicket of branches, it is wise to thin out

Jamesia americana.

some of the older wood occasionally, the younger branches producing the most and best flowers. The accompanying illustration gives a good idea of the inflorescence, whilst it also shows the woolly or felty character of the young shoots, which is a peculiarity of the plant. D.

Idesia polycarpa. — This ornamental-foliaged tree is worthy of extended cultivation in the south of England, for it is quite distinct from anything else in the outdoor garden, and, although the flowers are not very showy, the fruits are very attractive. It is a native of China and Japan, and was introduced from the former country about 1865. In its native country it grows 40 feet to 50 feet high, with a spreading head. The greenish-yellow flowers are borne in fairly large panicles, male and female blooms appearing on different trees. The latter are followed by small round fruits which are dark red or almost black when ripe and hang from the branches like bunches of Grapes. It is increased by seeds, and gives the best results when planted in well-

drained, loamy soil in a moderately sunny position. In a seedling state it is not very hardy, owing to the shoots being very vigorous and growing late.—D.

TREES WITH ORNAMENTAL BARK.

THE showy bark of various kinds of trees and shrubs has often been referred to, yet its beauty in winter is such that attention may well be directed to some of the more conspicuous subjects as a guide to intending planters at the present season. Perhaps when this colour is seen in the vicinity of water it is most highly appreciated, for on a sunny day there is the double effect of the mass of colour on the bank and the reflection in the water. This is particularly noticeable in the case of the yellow and red barked Willows and in *Cornus alba*, *C. Baileyi*, and *C. stolonifera*, the last three having red bark. Although the bark of mature plants is very bright, the colour is never so good as that of year-old shoots, hence many people cultivate them solely as one-year-old stems, cutting

them hard back near the ground-line just before growth begins in spring. *Berberis virescens* is another red-barked shrub, the young shoots having a decided ruddy glow in winter. A very rare red-barked tree is a variety of *Acer pennsylvanicum* called *erythrocladum*. In this case the bark is almost crimson, with occasional silvery marks. A yellow-barked Dogwood is found in *Cornus stolonifera* var. *flaviramea*, the variety thus differing very widely from the type, the bright red bark of which has suggested the common name of Red Osier Dogwood. *Alnus incana ramulis coccineis* is a form of the grey Alder, with reddish bark on the youngest branches and reddish buds.

There are many shrubs with bright brown bark, particularly *Ribes spectabile*, *Stephanandra flexuosa* and *S. Tanakæ*, the various kinds of *Philadelphus*, *Ribes sanguineum*, the *Hypericums* and *Neillias*, *Spiræas*, and many other subjects. Bright green is very noticeable in the *Brooms*, *Spartium junceum*, *Leycesteria formosa*, the *Ephedras*, and *Diostea juncea*, whilst white bark is conspicuous in *Salix daph-*

noides, *S. acutifolia*, *Rubus biflorus* and its variety *quinqueflorus*, *R. Giraldianus*, *R. lasiostylus*, *R. coreanus*, *R. thibetanus*, and various other kinds. Of the *Rubi*, *R. biflorus quinqueflorus* and *R. Giraldianus* are specially worthy of mention, the former by reason of its vigorous, erect stems 12 feet or more high and 1½ inches through at the base, and the latter by reason of the graceful poise of its long branches. *R. biflorus* is known by the common name of "Whitewashed-stemmed Bramble."

SILVERY STEMS are very noticeable amongst the Birches, the white trunk of *Betula verrucosa* being very attractive, especially when associated with Pines or other dark-leaved conifers. *B. papyrifera* (the Paper or Canoe Birch of N. America) and *B. Ermani* are other effective trees. Quite distinct from these is *B. nigra*, with very rough, reddish-brown bark, and *B. Maximowiczii*, with yellowish-brown bark. A yellow-barked tree is found in *Fraxinus excelsior aurea*, whilst the bark of the young shoots of several *Limes* is reddish-brown.

Less conspicuous than the Birches, but noticeable amongst other trees, are the Beeches, Hornbeam, and *Liquidambar styraciflua*, which have silvery-grey bark, whilst the green and brown bark of *Acer pennsylvanicum* and *A. rufinerve* is striped with silver and is very attractive. Bark-shedding trees like the Planes, *Arbutus Menziesii*, *A. Andrachne*, and the Lacebark Pine (*Pinus Bungeana*) are curious by reason of their piebald appearance due to the bark falling in patches. Amongst the *Roses* are several with reddish stems, *Rosa alpina* being specially noticeable. In addition to those mentioned, other attractively barked trees and shrubs will be called to mind, but those referred to are sufficient to direct attention to the merits of the class. D.

BRITISH TIMBER.

WHEN we consider that the total area of woodlands in this country is only a little over 3,000,000 acres, that fully 15,000,000 acres of waste lands exist, and that we annually import over 10,000,000 tons of timber at a cost of nearly £30,000,000, the necessity for an increased area of woodlands will be apparent to all, and the more so as a dearth of timber is imminent and outside supplies are being rigidly conserved, while our home demands are ever on the increase.

Taken as a whole, Europe has not enough timber to meet her demands, about 4,000,000 tons in excess of what she produces being annually required, and stringent laws have been passed regulating the output. This is the case with Norway, Sweden, Finland, and Russia. The Canadian forests and those of the United States are both nearly exhausted, and by a competent judge it has been said that in fifteen years little or no timber will be left if depletion goes on in those countries as at present. But the worst is that there are no forests to fall back upon, for the timber of those of Africa and India and South America is unsuited generally to our wants. Australia, China, and Japan require at present more timber than they produce.

Under such conditions the question naturally arises: What is the most feasible way to overcome the difficulty? In answer, and without the slightest hesitation, I would say that suitable waste lands at the rate of 40,000 acres should be planted annually, for a period of, say, twenty-five years. Such lands could, in England, Scotland, Wales, and Ireland, be gradually and cheaply acquired when the owner himself was unwilling to plant,

and in Ireland vast tracts of bog land would be willingly handed over at the present moment at a small sum per acre. Quite recently, in Wales, 7,412 acres of upland, described as "rough grazing and sheep walk," were sold by public auction for £15,670, or at the low rate of £2 2s. 3d. per acre. The land was particularly suitable for the growth of Larch, as the highly remunerative plantations adjoining clearly pointed out. But numerous similar cases could be given, so that the excuse of no available land is not tenable. They could be dealt with by a waste land reclamation society.

After careful computation I have no hesitation in saying that the area of plantations in the United Kingdom could at once be doubled by the planting of waste lands which at present do not bring in over 2s. per acre of rent annually, with infinite benefit to the country generally and a vast increase in the value of land, both to the owner and farmer who cultivates it. I have already suggested that altogether 1,000,000 acres should be planted over a period of twenty-five years at the rate of 40,000 acres per year, which would be an outlay of about £290,000 annually—a small sum, it will be admitted, when compared with the £25,000,000 yearly expended by this country on supplies brought from abroad.—A. D. WEBSTER, in *Country Life*.

ORNAMENTAL VINES.

A VINE-CLAD pergola is a charming addition to the garden, providing shade and coolness in summer and a gorgeous display of colour in autumn, especially if the top as well as the sides come under the eye. Unfortunately, in many cases the most attractive part of the pergola—the top—is obscured, owing to lack of foresight at the time of its erection. On undulating ground the whole of the pergola may be seen from various points, be the top flat or otherwise, but on level ground the gently-arching top helps the Vines to display their large and brilliant leaves from a distance. The Vine-covered pergola provides a cool, shady retreat during hot summer days, all the more if the path beneath is formed of old flagstones and not gravel, which is in constant need of repair through the continual drip in winter. The flagstone path, once properly laid, gives no further trouble. A climbing Rose or Clematis introduced at intervals increases the beauty of the Vines in summer before the leaves develop their rich colours. The pergola does not, by any means, exhaust the uses to which Vines may be put. Large tripods made of peeled Oak or Chestnut branches form excellent supports, which, on becoming furnished, stand out in striking contrast to the things around them, their noble foliage developing, under the sun's rays, gorgeous colours. I remember having seen *Vitis Coignetie* in Mr. Waterer's nursery at Knap Hill, where it had assumed enormous proportions. Planted near a large tree whose branches almost reached the ground, and threading its way among the lower branches, it had taken possession of the whole tree, which was of considerable height and spread, and in autumn gave a gorgeous display of colour. This treatment is not always possible, excepting in gardens of considerable extent. Where it can be done it is an excellent way to plant near the stem of the tree, training the Vine up through the centre and along the main branches until the whole tree is lightly furnished, after which its growth should be restricted. This is easily done when the leaves have fallen by pruning all side shoots back to two or three eyes each year, leaving only the main canes secured to the branches.

In this way the natural grace and beauty of the Vine will be preserved and the supporting tree—be it Apple or Pear—will lose none of its usefulness. The Japanese Vines are of the utmost value for this purpose and give delightful results.

The same treatment as regards pruning is necessary wherever the Vines are used, as otherwise the plant becomes a tangled mass which, in a few years, is beyond control and has lost much of its value. Where the Vines come into contact with a neighbouring tree they are almost sure to take possession of it, often with unexpected results. The Vines will flourish in any fairly good soil, although it is advisable to prepare the spot intended for them by digging a hole 2 feet square, filling with good loam to which have been added some well-decayed leaves, a little manure, and some lime-rubbish. A plant used here and there in a neighbouring hedgerow flourishes admirably and furnishes a beautiful splash of colour, usually a little earlier than in those grown in rich soil. On walls a large amount of their beauty is sacrificed, owing to the restriction usually found necessary to keep them in bounds. Unless a high wall, where all the growth made during the early part of the year can remain for its autumn effect, is available, it is unwise to grow Vines on walls.

Vitis quinquefolia (Virginian Creeper), *V. inconstans* (Ampelopsis Veitchi of gardens), and *V. Engelmanni* are usually grown on walls, etc., but they are extremely beautiful when allowed to ramble among evergreen-trees, such as Thujas, Ivies on fences, etc. The long, trailing growths hang from the former in autumn like crimson chains, whereas on fences of Ivy the growths may be allowed to fall like a curtain over the dark green Ivy, which is not injured in the slightest degree. I have planted large quantities of these Vines at the base of Oaks, Ashes, and Willows in the home woods, and in years to come these should form pictures of more than passing interest. A selection for the garden for autumn colour should include the following:—

VITIS ARMATA VEITCHI is a vigorous grower having large leaves of a brilliant colour in autumn. The long growths are thickly studded with short, thick spines, which look very pretty just as the leaves are falling.

V. COIGNETIE, a well-known and remarkably beautiful form, is one of the very best, and in the forests of Yezo is said to climb to the tops of the largest trees.

V. THUNBERGI is similar to the above, and for which it is often mistaken. It is distinct in its rather smaller leaves, which are deeply lobed.

V. VINIFERA VAR. PURPUREA (Teinturier Grape) is too rarely seen. The leaves, which with age develop a deep claret colour, remain on the Vine a long time and are about the last of the genus to fall. The sprays of leaves are lovely for cutting and using indoors.

V. HENRYANA is a rapid-growing kind with green cut leaves which are silvery-white down the mid-rib and veins. Usually this form is considered self-supporting, but I have found it, when a few years old, fall away from walls.

V. THOMSONI is a charming species, the leaves bright purple in a young stage, afterwards becoming a deep reddish-purple. It is of slender growth and could be used where the stronger-growing kinds are unsuitable.

V. FLEXUOSA WILSONI.—For low walls and limited spaces this is a charming variety, its tiny, smooth, glossy leaves being peculiarly attractive. Falling over a boulder in the rock garden it is happy.

V. MEGALOPHYLLA is a rampant climber, which, with me, has made in a season 14 feet of growth. Its leaves, more like those of an Aralia, are of a deep green colour which does not change. It is astonishing how rapidly it will ramble over a good-sized tree. If pruned to the ground each year it will, when well-established, run to the top of a 7-foot tripod and fall gracefully over, touching the ground on the opposite side. Its only drawback is that it possesses no great autumn beauty.

E. MARKHAM.

FRUIT.

GATHERING AND RIPENING LATE PEARS.

Good Pears are often spoiled by being gathered too soon and neglecting to help them with a little heat to bring up their flavour later on when their season for use draws near. This more especially refers to late Pears, which are supposed to be in season from Christmas onwards. During October and November there are generally in most gardens where Pears are grown more than can be consumed, but when the Christmas festivities are over there is not infrequently a scarcity of really good fruit. Late Pears should be left on the trees to the last hour they are capable of holding on. Early gathering means early ripening, if the fruits do not shrivel; in the latter case, of course, they are useless. Easter Beurré especially must be left on the tree as long as possible, as it has a habit of ripening before its proper season, though soil and situation have something to do with this. All late Pears should be kept in a dry, cool, dark room till about a fortnight before they are required for use, and should then be placed in a temperature of 60 degs. to ripen as required. If not the best Christmas Pear, Glou Morceau is certainly one of the best, and it rarely fails to bear on a wall. This should make a profitable sort to plant against the gable end of a lofty building in a good aspect, with the roots kept out of the cold subsoil, especially where this is clay, though I have found a subsoil of sand as injurious to Pear-trees when the roots penetrate it as clay. An excellent old winter Pear will be found in Winter Nelis, valuable not only for its excellent flavour, but also for its long time in season. If kept in the dark and taken into a temperature of 60 degs. a few at a time as required, its season will last for pretty well three months. Knight's Monarch is another old Pear that is excellent in point of flavour, and will keep in condition for several months. This is not much grown now. It never carries a very heavy crop, as when heavily laden it will generally cast some of its fruit. I have often seen the ground beneath the tree strewn with immature fruit. Doubtless a mulch of manure would check this habit of parting with its load. Olivier des Serres is an excellent late Pear, and deserves a place in every garden, its season being from February to March. Ne Plus Meuris generally bears freely, both on espaliers and also on walls. The finest and best samples come from a good aspect on a wall facing preferably south or southeast. Perhaps one of the most uncertain late Pears is Beurré Rance. I have had it delicious, and I have had it hardly so good as a Turnip. Bergamotte d'Espereu sometimes bears freely, especially on the Quince, but, though a well-flavoured Pear, it has not yet established its reputation as a free-bearing kind. Doyenné du Comice comes in before Christmas, and can, therefore, hardly be called a late Pear, but it is one of the best mid-season sorts and suc-

ceeds well on the Quince. Josephine de Malines has received a high character in the past, but it does not do well everywhere. Some years ago I tried it on the Quince, but it was not a success. The tree did not grow well and the Pears were gritty. This might have been due to the soil of the locality, as certain Pears are gritty on particular soils. H.

MORELLO CHERRIES.

I HAVE three trees on walls. They have been neglected, and are full of wood, which has grown irregularly and outwards. How should they be pruned?—J. ARTHUR.

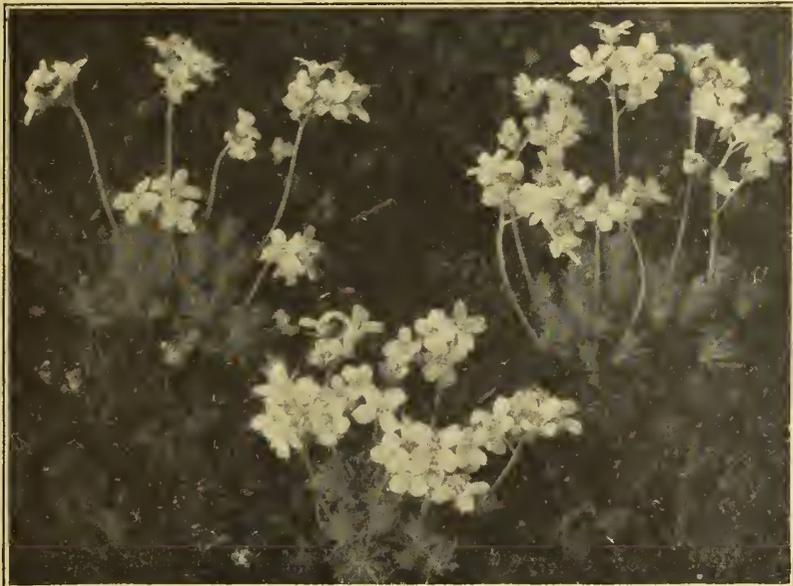

[Like the Peach, the Morello Cherry bears principally on the young wood made during the previous season. It is therefore imperative when pruning takes place to bear this fact in mind, and that care is taken to leave sufficient of it to furnish the trees in all parts both to yield fruit and to produce a further supply of young wood for future needs. The first thing to do in your case is to get rid of weak, decrepit, and dead wood. Then, as far as circumstances allow, cut away what in gardening parlance are termed "fore-

deficient of lime. Sometimes the bearing of a heavy crop of fruit will rectify matters when trees are inclined to produce a rather exuberant growth, but if they are really gross habited then root-pruning is the only efficient remedy.]

PEAR-TREES.

I HAVE two trees (bushes)—Pitmaston Duchess and Louise Bonne of Jersey. They are covered with bloom in the spring, but shortly after the fruit is formed it shrivels and falls off, apparently from frost. How can I protect them?—J. ARTHUR.

[Bush Pear-trees, if not of too great a height, can be protected to a great extent from the effects of frost with the aid of hurdles covered or thinly thatched with straw. In the case of young trees of no great height, these hurdles, if stood on end, can be made to meet, or lean one against the other at the top, and no further support is required, but in dealing with taller examples stakes are then needed to lean them against. Ordinary-sized hurdles are 8 feet in length, therefore when they are stood on end all round they afford protection to a considerable

Group of *Draba bruniaefolia* var. *incana*. From a photograph in Miss Willmott's garden at Warley Place, Great Warley, Essex.

rights"—i.e., shoots which grow out from the front part of or at right angles to the branches or wall, as these, owing to their position, are very difficult to lay in and secure to the face of the wall. After this give the remainder of the young wood a thinning, rejecting the strongest and weakest, and retaining that which is of medium strength and carrying an ample quantity of bloom buds. This thinning should be carried out to an extent that, when completed, enough young wood and no more remains to stand about 4 inches apart between the main and subsidiary branches when it is trained and nailed or tied, as the case may be, to the face of the wall. If the wood produced during the past season is excessively strong then root-pruning should follow the carrying out of the foregoing suggestions. To do this open out a trench some 3 feet to 4 feet distant from the stems of the trees and sever all roots met with when so doing. When no more roots are to be found pare the wounds on the severed roots smooth with a sharp knife and then refill the trench, mixing with the staple a little fresh loam and a liberal quantity of old lime rubbish also if the former is at all

portion of the tree in a vertical direction as well as laterally, or so that the upper portion alone would be left exposed. It is possible even then, when the height of the tree does not greatly exceed that of the hurdles, to protect that portion with scrim canvas or tiffany, or a few boughs of evergreens lightly disposed among the upper branches would effect the same purpose. The employment of the last-named in lieu of thatched hurdles would, if not used too liberally, ward off a considerable amount of frost, but owing to this kind of protection partaking of the nature of a permanency for the time being, or while the trees are in flower, and leading as it does to the exclusion of a certain amount of light and air, the method is not to be compared for efficiency with that of the use of hurdles. If you afford the trees protection this coming season on the lines indicated, and the result is of a negative character, then you may rest assured that the cause of failure lies at the roots and is not due to adverse weather conditions during the blooming period. The remedy in that event is to lift and replant the trees, or if too large and old for this to be done to root-prune them next autumn.]

NOTES AND REPLIES.

"Incision annulaire" on Vines.—I have been experimenting this season with the French method of ringing the current year's growth below the bunch of Grapes, and when the berries were just set and quite small. I tried the process on one bunch each of Muscat of Alexandria, Alicante, Madresfield Court, and Mrs. Pince, using the "Inciseur Pradine." In no case can I trace that it produced any definite result. It is claimed by some French growers that it tends to make the berries large, as the sap flow is stopped on its return and is concentrated in the bunch; also it is said to secure earlier ripening. Presumably, the "Incision annulaire" is applied to open-air Vines in France, and that may make the difference. My Vines are, of course, under glass. Have any of your readers any experience of this matter, and, if so, would they be good enough to impart it through your columns? The bunches which I operated on were just as good as those not treated, but neither better nor earlier, when ripe. I intend making a more extensive trial next year, and will report the result.—FREDERICK BOSTOCK, *Springfield, Cliftonville, Northampton.*

PLANTS AND FLOWERS.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

DRABA BRUNIAEFOLIA, VAR. INCANA.

THIS is not the *D. incana* hitherto known in commerce (which has white flowers), whereas *D. b. incana* has flowers of a lovely deep yellow on slender stalks 2 feet high, rising from a cushion of small hirsute rosettes forming a mossy green growth. The plants figured were growing at Warley Place. Seeds were, I believe, first sent in 1912 by W. Siehe, and, according to him, were collected in the Cappadocian Taurus. It is one of the first of all the *Drabas* to come into blossom, and is certainly an acquisition.

R. A. MALBY.

NOTES AND REPLIES.

Achillea tomentosa.—I think this is a satisfactory plant for the rock garden. It flowers twice in the year, and when crowded with its flat, deep-yellow heads of blossom is lovely, and, moreover, the flowers remain fresh and beautiful for weeks. It is almost as beautiful when out of flower, with its soft, ferny foliage of a lovely fresh green. I had a large patch of it in blossom up to the end of November, when there was little else in flower in the rock garden. It is a hungry feeder, and unless top-dressed each year will very quickly deteriorate. It does very well in sandy soil in a hot, dry position.—N. L.

Asperula hexaphylla.—Among hardy plants which can be safely divided and replanted at the present season may be mentioned this useful Woodruff. Of a moderate height, it is very desirable for cutting in the late spring months, its light and elegant panicles being well adapted for associating with cut flowers of various kinds, resembling as they do to some extent those of the popular *Gypsophila*. It will flourish quite as well in a shallow, sunny medium as in more retentive soil. Quite small pieces will in a season or two grow into useful clumps.—KIRK.

New Index and Binding Cases for completed Volume.—The Index to Volume XXXVII. of GARDENING ILLUSTRATED is now ready (price 3d., post free 3½d.). The Binding Case for the same volume is also available (price 1s. 6d., by post 1s. 9d.). The Index and Binding Case can be obtained from any newsagent, or from the Publisher, 63, Lincoln's Inn Fields, London, W.C. If ordered together, the price of the Index and Binding Case is 2s., post free.

FERNS.

THE COMMON HART'S-TONGUE

(SCOLOPENDRIUM VULGARE).

It is extraordinary how few people in Great Britain, except, perhaps, in the Midlands, seem to be aware what a capital window plant the common Hart's-tongue is given a little ordinary care, since it is at once quite hardy and quite evergreen. That its merits as a garden plant are more widely known is evident by the fact that at the autumnal holiday time an immense number of plants are to be noticed at the railway stations amongst the impedimenta of returning holiday-makers, who have gathered them during their stay in places where it is plentiful as a wild wayside plant. Its beauty under such conditions where it grows beneath the shelter of Devon and Dorset hedgebanks, to say nothing of the many other shires in England, Wales, and Ireland where it forms a prominent feature, is such that many—far too many, indeed—have been tempted to make such vandalistic raids upon it as to render it rare where normally it would be plentiful. To the true Fern-lover, however, it is pitiful to think how small a proportion of such acquisitions find subsequent proper treatment, while probably not one in a million finds a congenial home as a cherished window plant in the way I am advocating.

The Hart's-tongue is almost unique among British Ferns in having simple, undivided, strap-like fronds, smooth-edged, with a blunt tapering terminal, the blade commencing a few inches from the soil with two rounded lobes. At the back of these fronds in the autumn we find, as a rule, two rows of sausage-shaped brown masses, which are the spore heaps, and are arranged herring-bone-fashion on each side of the midrib, like the legs of a centipede (*Scolopendra*), whence the botanical name.

As an example of what can be done even with the common plants, I once saw a presumably very old specimen in a window facing the east, which filled it entirely with scores of fronds about 2 feet long with beautiful effect, the still green fronds of the previous season spreading loosely all around, and the new ones forming a promising mass in the centre. There are, however, innumerable abnormal forms of this species, which are far more beautiful, and consequently more worthy of such a place of honour, while equally hardy and easy of culture. Of these I would particularly call attention to the beautifully frilled varieties known as "crispum." In these, instead of a flat shape, each frond represents a deep frill, and is much broader, forming thus one of the handsomest decorative plants conceivable. Even more beautiful than these are the fringed *crispum* forms, in which the frond has fringes to the frills, greatly enhancing their charm. Some of the *crispum* forms, too, are tasselled or crested at their tips, the weight of these tassels bending over the fronds and thus imparting an additional graceful habit, which must be seen to be appreciated. Most of these charming types have in recent years been so far appreciated that several of our important trade growers have propagated them freely, and hence can supply them at very low prices—a shilling or so—thus permitting the acquisition of a specimen which, properly treated, will outlive the owner, and thus be "a thing of beauty and a joy for ever" so far as that owner is concerned. All that is needed in the way of culture is potting in a well-drained pot, not too large, in ordinary good garden soil containing plenty of leaf-mould, and kept well

watered. If the plant thrives as it should do it will, when obviously pot-bound, require a shift into a larger receptacle. In time the plants will form a number of crowns, or centres of growth. These, if carefully detached, will form independent plants, but, of course, if a large specimen be aimed at it is best left undivided.

I have only alluded here to one section of the varieties as being undoubtedly the most beautiful, but there are many more well worthy of cultivation, being varied in many ways by branching and tasselling, bunching and dwarfing, but these may well be left until the acquisition and successful culture of a "crispum" has converted its owner into an enthusiast.

CHAS. T. DRUERY.

GARDEN FOOD.

COOKING SPINACH BEET.

(REPLY TO "C. B.")

I HAVE always cooked Spinach Beet in the same way as ordinary Greens—in plenty of boiling water in which a very small pinch of bicarbonate of soda has been dissolved. When the Spinach is done the leaves sink into the water. It should then be turned into a colander and all the water pressed out with the back of a saucer; chop finely and return to the saucepan, adding salt and pepper and a little butter. Toss over the fire until very hot and serve in the same way as ordinary Spinach. The long, white stalks are nice if they are cooked separately and then chopped finely. Melt a little butter in a saucepan, and fry a dessertspoonful of butter for three minutes, then add a cupful of boiling milk, and simmer until smooth, add the chopped Beet stalks, and serve on slices of plain toast. Another method of cooking the Spinach Beet stalks is to boil them until tender, then take up and drain. Mix a pinch of cayenne pepper with a little salt, the juice of a Lemon, and a tablespoonful of Olive oil. Cut the stalks into 3-inch lengths, and lay them in the mixture of Lemon juice and Olive oil, taking care that all are equally covered with it. Mix a batter with two tablespoonfuls of flour, one egg, and sufficient milk to make the whole into a moderately thick batter. It is difficult to tell the exact amount of milk required, for eggs differ in size, and some kinds of flour absorb more moisture than others, but the batter should be thick enough to completely cover the pieces of stalk. Dip each piece of stalk separately in the batter and fry in deep fat until nicely browned. Drain on kitchen paper, and serve piled in the centre of a dish. White pepper can be used instead of cayenne if preferred.

The stalks are also nice if cooked *au gratin*. Boil them in plenty of salted water until tender, then take up and drain. Butter a fireproof dish, and lay the stalks in it. They should be cut into 4-inch lengths. Melt a dessertspoonful of butter in a saucepan, stir in a dessertspoonful of flour, and cook for five minutes, stirring the whole time, then add a cupful of boiling milk and continue stirring until the sauce is well blended. Mix in a tablespoonful of grated cheese, stir well, and pour over the Beet stalks. Mix half a cupful of fine bread-crumbs with a tablespoonful of grated cheese, a dessertspoonful of Parmesan cheese, a pinch of salt, and sufficient white pepper to flavour. Spread this mixture over the top of the sauce and stalks, dot with a few tiny bits of butter, and place in a hot oven until nicely browned. Serve very hot. This is a nice supper dish. Spinach stalks never get sufficiently tender to be rubbed through a sieve, the green parts of the leaves, however, if cut away from the

thick main ribs and cooked separately, could be easily passed through a coarse sieve in the same way as ordinary Spinach.

H. THORBURN-CLARKE.

NOTES AND REPLIES.

Poor Pears.—A Surrey man writes me a letter praising Pears that I know to be second-class, and as that is done in every catalogue I will not print what he writes. Among the Pears he likes are Souvenir de Congrès, Catillac, and Durondeau, which are not more than second or third class. He should compare Beurré d'Amanlis and Mme. Trevey. The Pears I praised as worth growing I grow, and my correspondent is quite welcome to see them.—W.

Poor Pears for market.—"E. H." says of the Pitmaston Pear:—

"Pear-growers know this Pear is no better than a Turnip, but it is a market fruit pure and simple. Its size and colour when ripe sell it, and I expect will continue to do so."

If this seems to justify growing a bad Pear it is wrong. What deserves a better fruit than the market? It is by growing a first-class fruit like the Newtown that the Americans have won the best market in the world for an Apple. So it would be far better for growers and the public if we supplied the markets with first-class fruit, as easily grown as the poorest. The term "a market fruit" should be dropped altogether; it now often seems a term implying the poorest quality. This should not be.—W.

Unleavened bread.—The *Lancet* for November 13th contains the following extract: "The fear of an exacerbation of the wheat crisis in Italy has interested not only those concerned in the manufacture of bread, but also medical hygienists in the search for an economical bread. The harm resulting from leavening bread has been made a special study by Professor A. Romano in the *Giornale della Reale Società Italiana di Igiene* for July. He states that the process of leavening makes bread too soft and renders it liable to be badly masticated and imperfectly mixed with saliva, especially when taken in milk or soup or dipped into various liquids according to prevailing Italian custom, when it is apt to be rapidly swallowed. The digestion of bread under these conditions is more or less imperfect, even though it does not necessarily reach the point of causing dyspeptic symptoms, and it is assimilated in less proportion to what it would be in normal circumstances. Moreover, the added yeast preserves part of its activity even after baking, and continues to ferment in the stomach, giving rise to the production of acetic and lactic acids, among other substances, which are harmful to those subject to an irritable state of the mucous membrane. Professor Romano insists, therefore, that the use of white leavened bread is a serious error in alimentary hygiene, while it also constitutes an enormous loss in domestic and national economy. He advises that bread should not only be made with wholemeal, but that it should not be subjected to the process of leavening.

The Walnut.—I was interested in reading the note by Mr. Farmer on the above in a December issue of *GARDENING ILLUSTRATED*. In this district (Highgate) I know of only one old garden where two or three Walnut-trees exist. In the West of England (Herefordshire in particular) they are quite numerous on old estates. My experience of the Walnut is that it crops—when established—regularly and freely, especially every second year. This being so, it is strange that it is not more freely planted. Gardeners should do their best to get a few specimens placed in or near fruit plantations, or elsewhere on the estate.—C. TURNER.

OUTDOOR PLANTS.

**LION'S TAIL (LEONURUS LEONITIS)
AT GARDEN DOOR.**

THE brilliant colour of this plant cannot be very well shown in an illustration.

rather a late bloomer, should make it one of the finest things one can have for the early autumn.

W.

ENGLISH PLANT NAMES.

[To the Editor of GARDENING ILLUSTRATED.]

SIR.—There is not the slightest doubt

to urge people to use Latin names to such an extent that it becomes pedantry in its most abhorrent form. Children and women and even those who are supposed to be botanists will never admit that *Bellis perennis flore-pleno* edging a border of *Centranthus ruber* sounds as nice or is as

The Lion's Tail (Leonurus Leonitis) in flower in a porch. October 20, 1915,

I just put it outside the south porch and between its shoots saw the landscape. It is a plant that should not be difficult to cultivate, though we do not always succeed with it. Greenhouse protection in winter and early growth in summer, as it is

that it would be a great pity to lose some of the fine English names, such as Wallflower, Sweet Sultan, Sweet William, Primrose, Snapdragon, Columbine, Daisy, and the like, and there is also no doubt that it is extremely foolish

easy to remember as Double Daisies edging a border of Valerian. I think Mr. Hornibrook wrote his article to be a warning to amateurs, and so far as I can see, after very carefully reading it over, there was nothing in it to try to persuade readers

to use Latin names to the extent of pedantry.

I quite agree with "W. R." that some Old English names are good, but I think that they want using with caution and not overdoing. I do not agree with any writer, and am afraid I shall never be persuaded to, who conscientiously advises the use of New English plant names instead of Latin ones. The catalogue referred to by Mr. Hornibrook is a marvellous production certainly, but it is stepping out in the wrong direction. Single Old English names are very good, such as Wallflower, etc., and I should defend others which lay claim to be Old English if they were not double or treble in meaning, but I severely denounce the efforts made to coin new Old English names.

I venture to say that amateur gardeners will find it nearly as hard to learn some of these New English plant names as they would to learn the Latin ones, and more than one amateur who is taking gardening seriously has told me that if he learns the English names he has to learn the botanical names first. If he does not, he gets into a muddle when he buys plants. If he asks for a Sneezewort he may get either an Helenium or an Achillea; if he asks for a Fleabane he may get an Erigeron or an Inula; if he asks for a Bellflower he may get anything out of the hundreds of species of Campanulas ranging in height from 3 inches to 6 feet or 7 feet; if he asks for a Campion he may get an Agrostemma or a Lychnis, and so on. Of course, it is all right if he does not care what he gets, but that is playing at gardening, and surely no readers of GARDENING ILLUSTRATED can be accused of that. I do not condemn good English names, but I do condemn the bad New English names, and I regard the Latin names of plants almost essential to the serious study of gardening.

E. T. ELLIS.

Westwood, Ecclesall, Sheffield.

[There is no word in the above that is against the right use of English names for plants, which is essential in our country. The belief that new English names are not good is a fatuous one. The Shamrock Pea and the Plantain Lily are examples of new English names. It is as reasonable to invent an English name as to coin Latin ones, and very dreadful ones are coined nowadays—double and treble ones—for hybrids, Orchids, and other plants. Whoever considers the question seriously should read the chapter on the subject in Mr. Ruskin's "Proserpina." We can give it no more space.—Ed.]

NOTES AND REPLIES.

Iris reticulata and its diseases.—Is not "Kirk," in his interesting note on page 1, assuming a little too much? The ravages of *Mystrosporium adustum* (Masse) appear in apparently all soils and positions, and are not easily checked when this Iris bulb scab once takes hold of a stock. The late Sir Michael Foster spent a considerable amount of time and thought in trying to cope with it, and found that lifting and setting aside bulbs which showed signs of the disease were necessary. Dr. M. C. Cooke says of it that: "Soaking the bulbs in a solution of one part formalin to three hundred parts of water will destroy the fungus, so long as it is external and has not penetrated deeply into the bulb." Mr. W. R. Dykes recommends the same treatment. This disease is frequently present in purchased bulbs, and it is always wise to examine these carefully. If black spots are present, I remove as much of the outer coating as is possible and destroy any bulbs which ap-

pear to be deeply affected. I have tried dipping them in flowers of sulphur, with apparent benefit, but the formalin treatment is more likely to be of real value. While soil and position must certainly have a great influence, I do not think that these alone will suffice once the disease gets a hold. Wherever it appears, annual lifting should be practised, all affected bulbs kept apart and either destroyed or planted away from the others after treating as suggested.—S. A.

Bellis cœrulescens.—It is unfortunate that this, referred to by E. Markham on page 7, is of doubtful hardiness, and that it is so frequently lost in winter. I have found that it is helpful if the blooms are cut off as they go past their best, and that plants thus treated have a better chance of surviving. Where self-sown seedlings appear it is not worth while doing this or wintering plants in a frame, but otherwise it is well to protect a few young plants under glass.—S. ARNOTT.

GARDEN PESTS AND FRIENDS.

SILVER LEAF IN FRUIT-TREES.

In recent years fruit-growers have suffered severe losses from a disease of fruit-trees which from want of a better name is known as Silver Leaf. Affected trees appear to be in perfect health and to present no external appearance of disease, except that instead of the vivid green commonly associated with healthy plants, the leaves—sometimes of a single branch only, at other times of the whole tree—have a silvery or leaden sheen, especially when looked at from an angle. Many kinds of trees are liable to be attacked, and in addition to fruit-trees it has been recorded in Horse Chestnuts, Sycamores, Laburnums, Portugal Laurels, Walnuts, Mock Oranges, and even in the white Dead Nettle and other herbaceous plants. The disease, however, is much more frequent in fruit-trees than other kinds of trees, and commoner in Plum-trees than in Apples, Cherries, Apricots, Peaches, Red Currants, and Gooseberries. The shade of silveriness varies, and not only is the colour of a silvered Apple leaf slightly different from that of a silvered Plum leaf, but a variation may be noticed in the foliage of a Victoria Plum and that of a Czar when attacked by the disease.

CAUSE OF THE DISEASE.—Although this disease is now very common in some parts of England and is known on the Continent of Europe as well as in South Africa, New Zealand, and Canada, the cause is not fully understood as yet, in spite of the scientific investigations into its nature which have been made both here and abroad. Most authorities are now agreed that in fruit-trees and certain other woody plants typical Silver Leaf may be caused by the presence of the fungus, *Stereum purpureum*, in the wood of the affected tree, and all the symptoms of the disease have been produced by artificially inoculating a healthy Plum-tree with a living part of this fungus, and even with the spores, under conditions which preclude the possibility of infection from other sources. But while we may assume that, unless there is evidence to the contrary, most cases of Silver Leaf in fully-grown Plum and Apple trees and perhaps also in other fruit-trees are due to this fungus, the following points must be remembered:—(1) The silvery appearance of the leaf is chiefly caused by the presence of air spaces immediately beneath the skin, which has a tendency to break away from the cells which lie beneath it. The change in the colour of the leaf, therefore, is due to the change in the light reflected from the surface, and not to the presence of the fungus in the leaf tissues. Where silvering is due to *Stereum purpureum* these changes in the leaf are to be attri-

buted to disturbances in the normal life of the branch induced by the presence of the fungus below. (2) In the case of certain plants, such as the Dead Nettle referred to above, and of certain seedling Plums, which have come under observation, no trace of fungus attack could be found, so that it is clear that silvering may be due to other causes than the presence of the fungus. (3) Leaves of many kinds of plants are often bleached by insect attacks and by other means, in such a way as to resemble Silver Leaf superficially. A little experience of true Silver Leaf in Plums, however, enables the observer to detect differences between the disease in question and these attacks without much difficulty.

PROGRESS OF THE DISEASE.—The usual course of an attack of true "Silver Leaf" in the case of a Plum-tree is as follows:—(a) A single branch of the affected tree develops the characteristic silvery sheen, the other branches remaining normal. (b) Several branches bear silvered foliage, often marked with brown flecks and streaks. Sometimes the leaves die as the summer advances. (c) Silvering becomes general, and the branches which have been affected longest die back. Sometimes a whole branch will die suddenly. (d) Several branches die and the tree bears a sickly appearance. Shoots low down on the trunk and suckers, both of which may or may not be silvered, often appear. These suckers cannot be successfully used for propagation. (e) The whole tree dies. Shortly after the death of a large branch the fructifications of *Stereum purpureum* generally appear on the bark, and after the death of the tree the fructifications appear on the trunk. According to Brooks, who has made a careful study of the disease, in the early stages of attack the wood is the only part affected, and frequently a narrow zone of the youngest wood remains uninvaded for some time, though sooner or later both this and the bark become affected. The fungus spreads much more rapidly lengthwise than across the wood, and in the case of the larger branches and trunk of the tree it may spread for a long time in the wood without any sign of injury to the bark being evident. The wood and the bark which are invaded by the fungus become dark brown in colour, chiefly owing to the presence of a gum-like substance in the cells. So abundant is the gum produced by the fungus in Plum-trees that large masses of it sometimes force their way out from the bark. The fungus may spread from the trunk into the roots of the tree. The amount of discoloured wood, as seen in the cross section of a silvered branch, varies according to the length of time the tissues have been affected by the fungus. The disease does not always appear in that part of the wood immediately adjoining the affected leaves. If, however, search be made further down the branch or in the trunk of the tree the brown stain will probably be found. It must be remembered that *Stereum purpureum* grows normally as a saprophyte on

DEAD WOOD, and that most of the wood of a healthy tree, though enclosed by a ring of living tissue, consists, especially in the inner and older part, of dead cells. It is on this part that the fungus begins its development. External development of the fungus takes place as the branches of the tree die so that fructifications of *Stereum purpureum* appear on the bark. These bodies are variable in shape and change their colour with age, so that they are not always easy to recognise. They usually appear in one or other of the following forms:—(1) Sometimes the fructifications appear as incrustations

several inches long covering the under surfaces of the branches or on the sides of the trunk. (2) At other times they appear as projections from the bark, of $\frac{1}{4}$ inch to 1 inch in width, and arranged in crowded rows one above the other. In this case the upper surface is hairy, but the spore-bearing surface beneath is smooth. When young and moist they are purplish in colour and leathery in consistency, but when dry they become dingy in colour and shrivel up. A spell of wet weather causes them to expand again, and each time that they do so they give rise to countless minute spores which spread the disease. These fructifications may appear at any time of the year, but they are commonest when the heavy rains which usually occur in autumn make the air and wood wet. When the spores of the fungus are liberated they are carried by the wind and may alight on a wound on another tree. There they would germinate, and the developing mycelium would live first

CHRYSANTHEMUMS.

SINGLE CHRYSANTHEMUMS.

Few who have grown single Chrysanthemums to any extent, or seen them grown by others, will deny that they are growing in public favour, and it is a wonder that they are not as extensively grown as the Japanese or incurved kinds. For cutting we have nothing better in the late autumn, and that fact alone should warrant their more extensive cultivation. Under good management the plants produce an immense quantity of bloom, and the flowers being light and graceful are admirably adapted for working into all kinds of floral decorations. For table decoration, too, single Chrysanthemums are unique. When lightly arranged with a spray or two of Fern or a sprig of autumn leaves or berries, they produce an exceedingly pretty effect. A few blooms thrust loosely into a vase with a spray of Asparagus

a practice cannot be too strongly condemned. When bushy plants some 2 feet or so in height at the same in width, and covered with trusses of bloom, are placed in a conservatory, they produce a pretty effect. The variety we figure to-day, a fine type of single, in colour pure white, was shown by Messrs. W. Wells and Co., Limited, at the meeting of the Royal Horticultural Society on December 7th of last year.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM DECEMBER 30TH.—*Winter Sweet (Ohimouautilus fragrans), Genista hirsuta, Hamamelis arborea, Daphne Mezereum, D. Dauphini, Strawberry-tree, Laurustinus, Garrya elliptica, Andromeda floribunda, Jasminum nudiflorum, Osmanthus ilicifolius, Erica mediterranea hybrida, E. m. glauca, E. alpina, E. carnea (in variety), Ivies, Polygala Chamæbuxus purpurea, Violets, Snowdrops, Winter Heliotrope, Polyanthus, Aubrietia, Violet Cress, Tufted Pansies.*

WORK OF THE WEEK.—Some good plants of *Arbutus Unedo Croomei* and *A. hybrida quercifolia* having come to hand a place has been given them on the fringe of the Heath garden; they have a carpet of *Erica mediterranea hybrida*. The *Arbutus* does well here, and apart from the wealth of blossom, the plants are, in most seasons, laden with the attractive red fruits. Several new varieties of Michaelmas Daisies have been added to a newly-planted border. A small group of *Ceanothus Veitchianus* has been planted on a rather warm piece of ground in the open, and others have been given the shelter of a wall. A few bulbs of the narrow-leaved Lily of the Field have been added to an existing group, which seems quite happy at the base of a wall facing south. A small batch of *Erica vagans rubra* has been planted in the Heath garden, and some old plants of *E. vulgaris Alporti* have been cleared away to make room for a few *Cistus algarvensis*, a distinct form of the Rock Rose. A group of *Deutzia Willsi* which had become uninteresting has been grubbed to make room for a colony of *Acer colchicum rubrum*, a beautiful autumn-tinted tree. A small group of *Andromeda floribunda* has been planted in a favourable position, and a number of *Eremuri* has been grouped among Himalayan *Rhododendrons* growing under Apple-trees. This position has been selected in order to try and extend the flowering season as much as possible. Pruning is now being pushed forward as rapidly as possible while the weather is mild. The various plants growing on the walls of the house are dealt with first. Climbing Roses are pruned back to three or four eyes, the old wood removed where necessary, and replaced by young, well-ripened growths. Clematises are merely thinned and extended where necessary. The young, thin growths of *Wistarias* are shortened back to about six eyes except where required for extension. E. M.

Sussex.

SOUTHERN COUNTIES.

Late Grapes.—These are, considering the adverse weather for weeks past, keeping remarkably well. To counteract the damp more fire-heat than usual has been employed. This keeps the internal atmosphere dry and buoyant, and prevents damp settling on the berries. In the case of a thin-skinned Grape like *Gros Colman*, damp speedily sets up decay. One effect of the use of this extra amount of fire-

Flower of single Chrysanthemum Flossy.

of all on the dead wood, but, as has already been explained, it attacks eventually the living wood. The spores, however, that give rise to the disease need not necessarily come from a tree of the same kind as the tree attacked. *Stereum purpureum* from a silvered Laburnum, for instance, may cause Silver Leaf in a Plum, and spores from the fungus growing as a saprophyte on Birch, Beech, Sycamore, or any other forest tree which has died from other causes, may infect another tree in the same manner. The presence, therefore, of this fungus on any dead wood in an orchard may be a source of infection even though no case of Silver Leaf is present. The wounds through which the fungus can enter may be quite small, but if a large surface is exposed, such as when a tree has been cut back and regrafted, or a branch has been broken by the wind or the weight of the fruit, the risk of infection is greater—*Leaflet No. 302, Board of Agriculture and Fisheries.*
(To be continued.)

plumosus will also produce an effect not altogether unworthy of notice. Apart from their value as cut flowers they are equally serviceable for conservatory decoration. When properly managed, plants of a dwarf, bushy growth can be obtained, and these literally covered with bloom. In addition to this, too, very dwarf plants can be grown that would be suitable for standing in vases in rooms or for table decoration, and it will thus be readily seen by those who have hitherto slighted Chrysanthemums how admirably adapted they are for all kinds of floral decoration. The treatment necessary to the successful cultivation of single Chrysanthemums is, of course, pretty much the same as is given to the ordinary kinds. No barbarous training should, however, be adopted, but the plants let grow in as natural a manner as is consistent with tidiness. The best way is to grow them as bushes in a similar manner to that practised in the case of Pompons. Occasionally disbudding is practised, but such

heat has been to improve the flavour of the last-named Grape, and in the case of a rod which resulted from the working of this variety on Madresfield Court Black Muscat some few years ago no fault could be found in this respect even by those who have an objection to Gros Colman when grown under ordinary conditions. The leaves, being ripe, are falling fast, and must be gathered up daily. Care is also taken to remove any berries showing the least sign of decay. Until an improvement in the weather takes place and drier conditions prevail bottling will be postponed.

Vine-pruning.—As fast as the foliage on other Vines matures this matter has attention, which leaves the rods ready for being relieved of loose bark and scrubbed when opportunity offers. The washing down of the structures and the necessary whitewashing are left for the outside hands on wet days.

Peach-house.—The trees in a house to be started six weeks hence will now be undertaken, so that the house can be cleaned the first convenient opportunity. Washing of the trees with an insecticide, and the subsequent dressing of stems, branches, and young wood with sulphur wash can then be done as time permits. With regard to the training and tying of the trees to the trellis the more experienced of the hands or such as train and nail fruit-trees outside will be pressed into the service to assist with this. It is only by arranging matters in this way that difficulties arising through the prevailing shortage of skilled labour can be overcome.

Pot Figs.—These may now be started, and if they are plunged and stood on something solid to prevent them moving out of place and surrounded with a good quantity of tree-leaves to afford a gentle bottom-heat the latter alone will suffice for some little time to come. If the bed is not provided with piping beneath it to afford a regular supply of artificial warmth when required later on a much larger body of leaves must be employed and be added to from time to time as becomes necessary. Leaves alone rarely become overheated, but at the same time if the trial stick or plunging thermometer indicates too great an amount of warmth the leaves must be removed from around the pots for a time, to be again replaced when the heat has begun to subside. A temperature of 50 degs. and 55 degs. suffices until the point buds begin to swell and the leaves to develop, when a further rise of 5 degs. to 10 degs. must be afforded. If well soaked at the start with tepid water but little moisture at the roots is required until new rootlets are emitted. Their appearance on the surface of the balls is the time to afford a top-dressing of turfy loam with a little old Mushroom-dung and bone-meal mixed with it, placing strips of zinc 4 inches to 5 inches wide just within the rims of the pots to hold it in place and to allow for ample supplies of water being given when the trees are in full growth. To induce the trees to break quickly syringing with tepid water twice daily is necessary, this to be accompanied by a damping of walls and paths at the same time. On bright mornings a little fresh air admitted at the top of the house is beneficial, but it should be shut off not later than 1 p.m.

Hardy fruit garden.—Owing to bad weather and other causes work in this department has fallen of late somewhat into arrears. An effort will now be made to expedite matters as far as possible so that spraying can be done before the season is too far advanced. With the exception of Peach-trees, which will be unnailed and loosened from the wall as usual, the amount of time expended on training, nail-

ing, and tying, as the case may be, will now be curtailed as much as possible in respect to wall-trained fruit-trees which have not yet been attended to. Pruning is, fortunately, well in hand, and will not take long to finish. The pruning of Peaches is usually left till last. These will have the young wood, where necessary, well thinned out, so that it will, when the trees are retrained, stand from 4 inches to 5 inches apart in all parts of the trees, which leaves space for the laying in of the current season's growths and admits of its becoming properly ripened. The young wood is, wherever possible, left full-length, but when shortening back cannot be avoided care is taken to do so either where there is a single wood-bud present or where one is situated between two flower-buds. As some small amount of brown scale is present on the older wood this will be got rid of before the trees are refastened to the wall. With the exception of the larger branches, which are tied with tarred twine, this is done with the aid of "medicated" shreds. These are preferable to ordinary shreds for the purpose, as insects avoid them and they can be used again and again or until they are no longer serviceable. For this reason the old shreds are taken care of when detaching the trees and again used when the retraining takes place. The latter operation is not and should never be done in a perfunctory manner, as nothing looks worse or detracts so much from the general upkeep of a garden as badly-trained Peach-trees. When properly done it is then time and labour well spent.

Seed orders.—Catalogues are now to hand, and the season's requirements, so far as they can be ascertained at this early date, will shortly be listed and the order dispatched. Although well-proved and standard varieties of both vegetables and flowers will continue to be grown, novelties to a certain extent will, as heretofore, be given a trial.

Broad Beans.—Where autumn sowing was omitted, or if the plants resulting from the latter do not look very promising, seed should be sown in pots or boxes. One of the early Longpod varieties answers well for this.

Cauliflowers.—With the exception of exposing the plants to a heavy downpour of rain they should be afforded all the air possible, otherwise growth will become drawn and too far advanced for the plants to be of service later on. In the event of their not wintering well it is advisable to make a sowing now under glass of one of the quickly-maturing or forcing varieties as they are termed; also of Early London and Walcheren, one pan or box of each, according to the number of plants required, sufficing. The receptacles should be placed in a greenhouse and covered with paper until the seeds germinate, after which a position on a shelf close up to the light to keep the plants dwarf and sturdy is necessary. Thin sowing is also very essential, otherwise the stems of the young plants will be liable to damp off.

Lettuce.—If the supply for salads is likely to run short Cos Lettuce seed should be sown thickly in boxes and cut afterwards when of the height of or in a similar manner to Mustard and Cress. Seed should also be sown of the varieties named Winter Gathering, Earliest of All, and Golden Queen to afford plants for cultivating in frames on a gentle hotbed for early spring use. The raising of the plants should be conducted in the manner mentioned with respect to Cauliflower seed. The varieties will succeed each other in the order named.

Radishes.—A sowing should be made in

a two-light frame on a hotbed of a very early variety, such as Early Rose; also of Early Frame, the one being oval in shape and the other long-rooted. A. W.

MIDLAND COUNTIES.

Peach-trees in bloom should be afforded a temperature of 50 degs. at night. Pollinate the flowers daily with a camel's-hair brush or small rabbit's-tail. Give the trees a constant circulation of air, avoiding cold draughts, and discontinue syringing the trees until the fruits are set, damping the paths and borders only. Succession-houses should now be kept closed, but without raising the temperature much for a week or two. See that the borders are moist and syringe the trees lightly on bright days. The cleaning and tying in late-houses should now be pushed forward. If the proper thinning out of the shoots was attended to as soon as the fruits were all gathered very little pruning at this season will be required. Both the trees and the houses should be thoroughly cleansed and the walls freshly lime-washed. If the trees are healthy and robust the border need only be watered before starting, otherwise the surface of the border should be removed and a dressing of fresh soil with artificial manure added.

Mignonette.—A small batch will now be sown in 4½-inch pots, using a compost of fibrous loam, leaf-mould, lime-rubble, and sand, placing the pots in a warm pit.

Chrysanthemum cuttings should be examined carefully and any that are rooted stood near the roof-glass, where air can be given. If cuttings of certain varieties were not obtainable earlier suitable shoots should be inserted without delay.

Cyclamens.—The first batch of these is now in full flower. Maintain a buoyant atmosphere of about 55 degs., and afford weak stimulants occasionally. The later batches will be benefited by a light top-dressing of loamy soil containing a little chemical manure. Remove a little of the surface soil with a pointed stick, taking care not to damage the roots or corms. Seedling Cyclamens which were sown during September have made three or four leaves, and are potted off singly into small 60-size pots, the compost consisting of equal parts loam, peat, and Oak leaves rubbed through ¼-inch sieve, adding a little coarse sand and charcoal. The young plants are kept close to the glass in a temperature of 65 degs., sprayed on fine days and fumigated occasionally.

Seed-sowing.—Seeds of certain plants for planting out in the late spring will be sown during the present month. These include Antirrhinums, fibrous and tuberous rooted Begonias, *Verbena venosa*, *Gilia coronopifolia*, *Pentstemons*, including *P. speciosus* and *P. heterophyllus*, *Salvia splendens* var. *Zurich*, *Delphiniums* for autumn-flowering, *Hollyhocks*, perennial *Lobelia* *Queen Victoria* and *cardinalis*, *Cannas*, and other sub-tropical plants. All these seeds need a stove temperature to cause them to germinate quickly, and the seedlings should be pricked out as soon as they are large enough to handle.

East Lothian Stocks are valuable for the flower garden. Sow the seeds in boxes or pans from the middle to the end of the month, and place in gentle heat, ainery which has been started about a month being a suitable place. Cover the boxes or pans with glass and shade with paper till the seedlings appear, then place them where they will get plenty of light. As soon as they are large enough to handle prick them out singly into 3-inch pots, place them again in a warm house to give

them a start, and they will soon make a little growth and begin to fill the pots with roots. They should then be placed in a cold frame, which should be kept close for a few days and covered at night if the weather is frosty. Afterwards air should be given whenever the weather is favourable. Gradually harden them off until they are ready for planting out early in May. The soil in which East Lothian Stocks are planted should not be too rich, or they will grow very strong and not flower so well.

Early-flowering Chrysanthemums.—The clumps which were dug up in the autumn and placed in cold frames have developed plenty of shoots suitable for cuttings. The

pot, and room should be left when sowing for an inch of top-dressing when the pots are filled with roots. Place the pots in cold frames or cool houses. When germination has taken place abundance of light is essential or the seedlings will become drawn. All the air that the weather will allow should be given, in order to harden them in readiness for planting out when the weather is suitable. I always treat the first two sowings in this way, as by so doing I have them under control from the ravages of vermin, such as rats, mice, birds, and slugs, and they are easily protected during severe weather. If carefully handled when planting no perceptible check will be given, and if staked and

sown every fortnight in pots measuring 7 inches or 8 inches in diameter, using a compost of a moderately light texture mixed with a fair amount of road grit. Water the seeds immediately they are sown, and start them in the forcing-house. Earlier-raised plants must be afforded all the light possible, and for this reason the plants should be stood on shelves near to the roof-glass. Maintain a temperature of from 60 degs. to 65 degs. The shoots should be stopped immediately they are long enough. Whenever the weather permits, the foliage should be syringed once or twice daily to keep the plants free from red spider. The growths should be supported by placing fine twigs from old birch-brooms in the pots. Ne Plus Ultra, Canadian Wonder, and Masterpiece are excellent varieties for forcing.

F. W. GALLOP.

SCOTLAND.

Wall-trees.—In spite of weather drawbacks the work upon the walls was completed in the course of the week, with the exception of the training of Peaches and of Nectarines. These generally make their best growth during the autumn, consequently their period of ripening is delayed, and, from that, it follows that pruning and training must of necessity be later than is the case with fruit-trees which mature their growths at an earlier date. Meantime, a look-round has been given to the trees, obtrusive and evidently superfluous growths were removed, and, so far as possible, the forthcoming work of training was anticipated. The majority of the walls upon which Peaches and Nectarines are grown is now wired, this making the usual yearly work more speedily overtaken.

Shrubberies and snowfalls.—As has been indicated in previous notes, the snowfall of the later months of 1915 has been in excess of the average. Heavy snowfalls are all to the disadvantage of the finer shrubs, Yews, Bamboos, Choisyas, Pampas Grasses, and so on. The practice followed here is to shake off the accumulations of snow as soon as possible, and for this purpose long, light poles of Bamboo or of Ash are unequalled. During the week a considerable bulk of snow was dislodged from the shrubs above mentioned, any possible damage being thereby averted. Permanent erections of wire-netting over Gooseberry and Currant breaks should be similarly attended to. The snow gathers much more quickly than is realised on such erections, and the weight on the posts is apt to be dangerous. In this case, although it is a wet and very unpleasant job, the best plan is to beat the netting from the inside of the erection, and for this purpose the use of wooden rakes is to be preferred. The snow is readily dislodged by light beatings with the head of the rake, keeping, of course, the teeth downward.

Gesneras.—The latest batch of Gesneras has been gradually dried off and will now be kept without moisture for a time. I wonder why these accommodating plants are so often passed over in favour of others which are much more difficult to manage and which do not give the same satisfaction. Apart from their blooms the foliage of Gesneras is not unattractive, but, of course, to see the foliage at its best the temperature of the stove is needed. Gesneras will bloom well in the greenhouse in the summer, but they are more useful in December and January when grown as stove winter-flowering plants. I prefer to raise my stock annually from leaf cuttings. The corms—which are freely produced—from the old plants are apt to be deficient of vitality. This I have proved

Michaelmas Daisies in a vase.

roots may be divided and potted up, or cuttings may be taken and inserted in boxes of sandy soil placed in a frost-proof pit. I prefer to propagate from cuttings, as I find these make the better plants. Of the many beautiful varieties obtainable Countess, Elsingham White, Horace Martin, Carrie, Leslie, Polly, Blush Beauty, Improved Masse, Normandie, and Goacher's Crimson are a few of my favourites.

Early Peas.—The first sowing of Peas for planting on a warm border will be made at once in 3-inch pots. The compost will consist largely of loam with some old Mushroom-bed manure rubbed through a sieve and mixed in to enrich it. Five plump seeds will be enough for a 3-inch

netted at the same time the crop is practically ensured.

Onions.—If large bulbs are wished for, seed of the best kinds should now be sown in boxes and raised under glass. The most suitable structure is an early vinery or Peach-house which is being started. The boxes should be well drained and filled with a mixture of good loam, leaf-soil, and coarse sand. Use it in a moderately fine, dry condition, and make very firm. Sow the seeds thinly and evenly.

Leeks.—Where large specimens are required seed should be sown in the same manner as advised for Onions above.

French Beans.—To maintain a regular supply of Beans a small batch will now be

by experiment, the most probable reason being that the drain upon the growing plants reacts adversely upon the corms which they form. Hence it is that Gesneras are generally grown from seed, but I fancy that if healthy and robust leaves be taken and used as cuttings the result would be quite satisfactory.

Greenhouses.—Following upon the passing of the Chrysanthemums a good deal of re-arranging has been done during the week. Use has again been made of large Palms which, since October, have been left pretty much to themselves. There can be no two opinions as to the value of these plants and of Tree Ferns at this season of the year. Their green leaves are always attractive, and, after all, they are quite as ornamental as forced pieces of Staphyleas, Acers, and so forth, and, in addition, they are much more easily managed and much less liable to come to grief. I venture to prophesy that, as a result of existing conditions, more use will be made of these semi-hardy subjects. The Dicksonias, Alsophilas, and Lomarias among Ferns, and the Acacias, Hibbertias, and Oleanders among greenhouse plants of a former generation, may quite easily again come to their own. Some of us, at least, would be glad to welcome them back. We are now letting the various kinds of Primula bloom. These have been kept back for some time, with a view to utilising them when the Chrysanthemums were practically over. Seldom has *P. malacoides* promised better. The plants were grown on shelves near the light, and, as a result, the foliage is healthy and vigorous, and the flower-spikes exceptionally numerous. *P. sinensis* is, perhaps, scarcely so satisfactory. The plants never really recovered from errors in watering after they went into their flowering-pots, and it is difficult at this time to supervise everything. We are still delaying *P. obeonica*, which I find more useful in the spring. A spare batch of Begonia Gloire de Lorraine has been given greenhouse treatment. These are well in bloom and may be expected to last for some time. A good batch of *Schizanthus Wisetonensis* has been removed from shelves to a stage in a moderately warm house. These plants, at present in 5-inch pots, have been pinched, and in a short time will be repotted into 8-inch pots. Similar treatment has been given to a batch of *Alonsoa incisifolia*, but in their case no repotting will be done, the plants remaining in 5-inch pots. In the course of re-staging, apart from Chrysanthemums, a good many plants have been discarded. One is always sorry to throw out plants, but the near approach of the propagating season makes this work needful.

Forcing.—Further supplies of Asparagns, Seakale, and Rhubarb have been put into heat. At this time forcing is more easily carried out, and the produce is better than that which was excited into growth at an earlier date. Plenty of moisture is needed when forcing is done by means of hot-water pipes, but when the crowns are being forwarded on hotbeds, or in a Mushroom-house, less moisture will be required. In any case, while forcing is going on, too much water is no more dangerous than too little.

Outside work, meantime, remains at a standstill. Rose-planting, etc., has been delayed, and no attempt will be made to hasten the work till the soil conditions are more favourable. Rainstorms, snowstorms, frosts, severe though fleeting, and a steady volume of wind from the north-east will apparently finish the year.

W. McGUFFOC.

Balmac Gardens, Kirkcudbright.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Agrostis pulchella (C.).—This very pretty Grass is an annual, and grows from 9 inches to 1 foot high. Sow each year at the end of May in small clumps on the herbaceous or flower border, and, covered slightly with fine soil, it will grow freely and be very acceptable for cutting at a time when the beauty of many things outside is failing. It requires no more care while growing than keeping free from weeds, and a few small stakes and some matting placed round the clumps to prevent the wind from blowing them to the ground.

Planting Liliums (A. E.).—If your bulbs have just been imported they should be carefully examined and all decaying matter removed. They then should be laid in Cocoa-nut fibre, moderately moist, until the bulbs recover their plumpness and roots are beginning to appear from the base. Then they should be planted out or potted as may be required. Before doing this, however, see that all decaying scales are removed, as a few of the outside ones are often bruised in transit, and after they have been in the soil for a little time decay sets in and contaminates the whole bulb.

Salvia patens (J. L.).—The plants should be lifted from the open ground, and, after the soil has been well shaken off the roots, be placed in fine, dry soil in a greenhouse or in a cold-frame, and be so far protected that frost shall not reach them. In this way the roots keep better than when dried and put away in sand or on a shelf. Plants in pots should have the stems cut down and be stood under a greenhouse stage till March. These, if brought into the light then, will start into growth, and young shoots thus produced make fine cuttings. The roots may be put into the open air in spring.

Growing Begonia Gloire de Lorraine (Salopian).—The culture of Begonia Gloire de Lorraine is not at all difficult, the principal thing being to obtain good cuttings in the spring, as the plant, being so free blooming, continues to bloom instead of growing, and it is useless to propagate from cuttings of the flowering shoots. After flowering, the old plants should be cut back, and young shoots will push from the base. These shoots, when from 1½ inches to 2 inches long, make the best of cuttings. Put them into well-drained pots filled with sandy soil, and stand in a close propagating case, where they will soon root and should be potted on as required.

The young plants do best in a gentle heat early in the year. Later on they may be grown in a greenhouse or frame, but in the autumn, heat is again necessary. A mixture of loam and leaf-mould, with a sprinkling of sand, will suit this Begonia, and when the pots are well filled with roots an occasional dose of liquid-manure is very beneficial. See also the "Week's Work." No leaves were enclosed with your letter. Kindly send some on, and we will do our best to help you.

SHORT REPLIES.

Mrs. Northey.—Clematis Nelly Moser belongs to the lanuginosa set, and must be pruned as recommended in the answer to "J. Arthur," in our issue of January 8th, page 26. We do not know the variety Gloire de Lorraine.—**Sunflower.**—It is impossible to advise you as to treatment unless you send us some flowers and leaves or tell us the name of the Begonia you refer to.—**A. B. G.**—See reply to "Mrs. Northey," above.

NAMES OF PLANTS AND FRUITS.

Names of fruits.—**L. W. G.**—Apple not recognised.—**Mrs. Newth.**—Apple is Graham.

OBITUARY.

MR. S. W. FITZHERBERT.

MANY garden lovers will hear with regret of the death of Mr. Wyndham Fitzherbert on December 20th, suddenly, while helping friends whose gardeners have gone to the front. He was a gentleman of high culture, and deeply interested in all rural things, and his notes on plants and gardens were most precious.

The Charm of a Garden.

PREPARE now that your garden this year may be a perfect picture, full of glorious bloom and sweet perfume. Think of the summer and scent of Sweet Peas, and remember that Eckford's Sweet Peas are recognised by experts as the finest one can possibly grow. Below we give a list of our most popular Collections that will make your garden a veritable wealth of bloom right on until the Autumn.

Genuine Eckford Seeds can only be obtained direct from Wem. No Agents are employed.

Special Sweet Pea Collections for 1916.

Exhibitor's 'A' Collection

40 Splendid Waved Varieties. This collection includes a half packet of each of 20 novelties. The number of seeds, other than Novelties, will be 20. This is splendid value. Price 15s., post free for cash.

Exhibitor's 'C' Collection

24 Splendid Waved Varieties, excellent for any purpose, fine for exhibition. 12 seeds of each. Price 5s. 6d., post free for cash.

Exhibitor's 'D' Collection

13 Splendid Waved Varieties, excellent for any purpose, fine for exhibition. 12 seeds of each. Price 2s. 9d., post free for cash.

Villa 'A' Collection.

50 Splendid Varieties, 25 Seeds of each, exquisite for garden effect and cutting. All free flowering and strong. A fine range of colour. Price 10s., post free for cash.

Villa 'B' Collection.

24 Varieties. A splendid range of colour for garden effect and cutting. 50 seeds of each. Price 5s. 6d., post free for cash.

Villa 'D' Collection.

12 Varieties. The same as Villa "C" exactly, only 25 seeds of each variety. Price 1s. 6d., post free for cash.

We also send a specially written Booklet on the Culture of Sweet Peas FREE with each collection.

FREE Send a Post Card to-day for large Illustrated Catalogue. It gives all particulars of the NEW SWEET PEAS for 1916, and contains a full list of ALL FLOWER and VEGETABLE SEEDS necessary for your garden.

HENRY ECKFORD, F.R.H.S., Seed Grower and Specialist, (Dept. 64), WEM, SHROPSHIRE.

NOTES OF THE WEEK.

Viola cornuta Papilio.—This is hardly ever out of flower. It is perhaps not very perennial, but it seeds itself so freely that once established it is not likely to be lost. It comes up in all sorts of odd corners but never seems to be in the way, as it rarely interferes with its neighbours, as so many of the free-seeders do. Here, within a few days of Christmas, there are several of its delicate blossoms to be seen scattered about in the rock garden, in spite of the frosty weather we had in November.—N. L.

The Shamrock Pea (*Parochetus communis*).—There are, unfortunately, few places in Scotland, except on the western seaboard, where this, referred to by E. Markham in his article on "Storm proof plants," can be accounted hardy. One can only hope that Mr. Markham's note may be the means of introducing it to the gardens of those in the milder parts of the United Kingdom. It is a delightful plant when trailing over rocks, and is very effective as a vase or tub plant.—S. ARNOTT.

Paliurus australis (Christ's Thorn).—I saw a small specimen of this interesting tree on September 27th of last year in Peckham Rye Park, when it was in bloom. The little flowers are greenish-yellow, but quite attractive, as they peep from among the Acacia-like leaves in great numbers. It is said to be hardy and has been cultivated in this country for many years, but one rarely comes across it nowadays. It is well worth a place in the garden, being of more than usual interest inasmuch as the Crown of thorns was supposed to have been made from its branches, which have sharp spines.—E. M.

Ozothamnus rosmarinifolius.—It is to be hoped that the illustration of *Ozothamnus rosmarinifolius*, on page 17, may enlist the consideration of gardeners in mild districts in the United Kingdom. It is a delightful shrub, especially against a wall, its only drawback being that it is not thoroughly hardy in the British Isles. Within the last ten years it suffered greatly on a south-west wall in my garden. A good plant was badly cut one year, and two winters later, when we had a specially severe time, immediately following a mild spell, this plant succumbed. In the Royal Botanic Gardens at Glasnevin it is magnificent.—S. ARNOTT, Maxwelltown, Dumfries.

"The Journal of Horticulture."—This respectable, and at one time very popular and useful, journal has now, after many years of good work, ceased publication from causes due to the war. At one time it had on it as writers some of the best gardeners of the day.

Morisia hypogæa.—A week before Christmas I was delighted to find three lovely blossoms and several more buds on a plant of this in the rock garden. I suppose the mild weather tempted it, as it did a plant of *Saxifraga sancta* near by, which was also showing a spike of untimely, though very welcome, bloom. Many people seem to find a difficulty in growing *Morisia hypogæa*, but in my garden in London it seems very easy. I grow it in a steep, sloping pocket, in soil which contains a large proportion of crushed brick and old mortar. I find a great many things appreciate crushed brick, as it keeps the soil open and also, it seems to me, is warm and dry even in wet weather.—N. L.

The autumnal Snowdrops.—Looking through the garden to-day (January 3rd) after a lull in the fierce storms we have had of late, one observed a considerable advance in the early bulbs. One outstanding fact has been the lateness of the "autumnal-flowering" Snowdrops. At present none of them have come into flower, and the furthest advanced is *Galanthus octobrensis*. As I have remarked on previous occasions, these autumnal Snowdrops have shown in most years a tendency to come into line with their sisters, the "Fair Maids of February," but I have not, I think, seen them so late before. To-day *Galanthus octobrensis* is above ground and showing a little white beneath the spathe. Probably the lateness is due to the long spell of cold and frosty weather experienced early in autumn.—S. ARNOTT.

Pyracantha angustifolia.—This evergreen shrub is now loaded with its orange-yellow fruits, which develop a deeper tint with age, and remain on the plant well into late spring; quite unlike those of the well-known *P. coccinea*, which are devoured by birds as soon as they are ripe. With me, *P. angustifolia*, which fruits annually, is growing out of a group of *Cotoneaster pannosa* in the open garden, and is quite 10 feet in height. It is sometimes known as *Cotoneaster angustifolia*, but its sharp thorns and general habit of growth are those of the *Pyracantha*; also the fruit is displayed in the same clustering manner. For cutting at this season

of the year this is most valuable, as sprays 18 inches to 2 feet long may be obtained. The shrub is also attractive when in bloom.—E. M.

Snowdrops.—Snowdrops appear to be late this season. As yet (January 6th) there are no signs of any flowers. Reference to the garden book gives the following dates for recent years: 1915, January 1st; 1914, December 27th; 1913, January 8th; 1912, January 5th; 1911, January 3rd; 1910, December 29th. The latest year of the past twenty was 1904, the date being January 16. These dates refer to the first fully expanded flowers, not to blooms picked as harbingers before being open.—W. McG., Balmac.

Accidental combinations.—A few of these having of late been referred to in GARDENING ILLUSTRATED is my reason for recording a note I made in early autumn of such result. It occurred in the rock garden. Some shoots of a strong-growing plant of *Verbena chamædrifolia* crept over the ground and found their way up between a small group of the Lavender Cotton (*Santolina*) that happened to be close by. Such a blending had never suggested itself before, and the effect was a really good one. I resolved to try, whenever opportunity offers, a bed of the ordinary scarlet bedding *Verbena* with a few plants of the above grey-leaved subject interspersed among the *Verbena*. *Santolina Chamæcyparissus* is, perhaps, the best-known variety, but *S. incana* would, I think, prove a better dot plant.—C. TURNER.

A note from Ashbourne.—The warm weather is producing great colour—the Dahurian *Rhododendrons* are covered with their light and dark-mauve flowers, and the Witch-hazel (*Ilex mammosa*) is one blaze of golden-yellow. The shrub, named by T. Smith *Cornus officinalis*, is just breaking out into blossom, citron-yellow, and the early Cherry (*Cerasus Miquelliana*) started to flower in December and will continue blooming until March. *Iris stylosa* is also sending up its flower-spikes, while the Heath is coming into bud, and even showing colour, though only planted in the late autumn. The *Hellebores* are also one mass of white flowers. I feel sure that they require deep, rich soil, and then must be left undisturbed in partial shade and in ground well drained. At first they gather strength, but in time they flower freely. We are so proud, as we have discovered thirty blooms on *Magnolia Campbellii*, for the first time,

but which indicates regular annual flowering hereafter. It is a glorious tree when the frosts respect it.—R. H. BEAMISH.

Gentiana acaulis in London.—I planted this in my London garden in 1914, but had little hope that it would do much good, and I am afraid I did not take much trouble over it. I put it into a low pocket of a bed of Heath, in soil composed of leaf-mould and grit, the surface dressed with a few stones. It was only a small plant, and I did not get any flowers in the spring of 1915, but in October it threw up a bud which I regarded at first with scepticism, but afterwards with much interest, as, to my great pleasure, it opened on a sunny day in the middle of November. It seems a very uncertain species as to flowering, and I do not suppose the atmospheric conditions of a London garden are much help to it, still, if it flowers once, it should flower again, and I shall take much more interest in it now. The friend who sent it to me told me that the secret of success was to see that it never got dry in summer, and no doubt a mulching of stone helps it greatly in this respect.—N. L.

FRUIT.

THE BAGGING OF PEARS.

I would refer F. L. Clark, Yorks., who writes *re* above in your issue of January 8th, to my note, p. 772, December 25th, 1915, of GARDENING ILLUSTRATED. Of course, muslin, or, better, tanned scrim, bags are best of all for fruit preservation. It is, as regards ripening, immaterial whether muslin or paper bags are used. Maturing of fruit on the trees is greatly influenced by inward warmth, not outward, I think. Paper bags preserve better the outward appearance of fruit; they are cheap, and being so are not worth preserving for another season, no little item among other details of the fruit garden. Your correspondent cannot do better than use either paper or muslin, as best suits his convenience, so long as he preserves his fruit from birds. Should only a hundred or so Pears require bagging, muslin would be best, but where thousands are in question paper bags, I think, will be found more economical and easier handled. Personally, I think paper bags, if such are strong, like used for tea, are even better protection from birds than muslin or scrim, for with network bags birds or wasps work through the net, whereas paper screens all from view, and unless fairly sodden by rains I have found a complete protection afforded by paper. As regards observing state of fruit that is not necessary, as anyone who knows will find when they are ready to pick by trying by hand.—W. C. F., Jersey.

—It will be well for Mr. Clark (page 15) to stick to his muslin bags, for of two necessary evils they are certainly preferable to paper. Something of the kind is probably required under certain conditions as a protection against birds and wasps, but it is very difficult to accept the statement made in a recent number that the flavour of the fruit is improved by enclosure in paper bags. On the contrary, all experience points to the desirability of a maximum of light and air to attain this. It may be desirable to bag the softer fruits that wasps and earwigs are able to tap unaided, like ripe Peaches, Plums, and especially Figs, but so far as wall and small bush and pyramid Pears and choice Apples were concerned I found $\frac{1}{2}$ -inch fish-netting answer the purpose admirably, this preventing the tapping by tits and the after attack of wasps. Certainly the flavour of a Doyenné du Comice or Beurré

Hardy Pear would not be improved by enclosing the fruit in a paper bag.—E. B. S., *Hardwick*.

—I tried paper bags this year with Pitmaston Duchess (the grease-proof bags made for cooking some years ago). I did not find that the Pears ripened in them, and where tied earwigs congregated; and again, the wet showers opened the lower edge of bags where joined. I shall in future try butter muslin, as suggested by F. L. Clark, as paper excludes all sun and prevents ripening.—T. K. S., *Norfolk*.

—In reply to F. L. Clark's, Yorks, inquiry in your issue of January 1st, the paper bags would last two or three times with care if made of good paper. The advantage of paper over muslin bags for Pears is they are much more easily and quickly put on. As regards the question of sunshine, I have not found the paper bags detrimental to the flavour of the Pears. Of course, any bag will interfere a bit with the colour. Paper bags will keep the Pears much cleaner than muslin, and if the mesh of the latter is too wide there is a risk from insects like saw-flies, etc. With regard to Apples, muslin or some similar material is better in practice, as it is difficult to put paper bags over them. There is one other point in favour of paper bags for Pears—viz., they keep the temperature more uniform and warmer at night. In conclusion, I consider paper bags best for Pears and muslin bags for Apples.—E. B., *Springfield, Northants*.

PEARS STANDARD AND CORDON.

The illustration of a standard Beurré Hardy Pear in a recent number, with notes on the same, shows a well-grown, shapely tree, and tells of what may be done in the way of growing high-class Pears in a form to which we are more accustomed in old sorts of less merit like Autumn Bergamot, Windsor, Swan's Egg, and the like, of which there are standards of large size in many English counties. I notice by the illustration that the tree was well cared for from the first, and not allowed to grow at will as in the case of the majority of the old sorts above noted. The majority of the best Pears of medium size in their respective seasons might doubtless be satisfactorily grown in this way if space permits, giving after a time a good return and occupying less space than straggling bushes or pyramids, but for small gardens, if a quick return in considerable variety is a consideration, I do not think one could do better than plant cordons. There are a few sorts not altogether satisfactory on the Quince, but I think it may be taken for granted that most of the best will do very well in this way, and come very quickly into bearing. A few that I have proved are Doyenné du Comice, Thompson's, Louise Bonne, Beurré d'Amanlis, B. Hardy, and B. Alexandre Lucas. How do the standard Pears fare with the spring frosts? I should think rather badly in many seasons, for the blossom is very sensitive and succumbs to the slightest frost if at all damp. It is here that the advantage is with the cordons, for whether on wall or rough, home-made fence they can be easily and cheaply protected, and with this, given careful cultivation in other matters, an annual crop is a practical certainty, and it must be remembered that this is a very quick business from the maiden tree stage.

I noted above that another point in favour of cordons was securing variety in a small compass, and this is indirectly emphasised by a communication from a correspondent on page 728, where we read of a quarter of a ton of Dr. Jules Guyot Pear from one tree. This is all very well from a market point of view, but prac-

tically useless for a private place, as nine-tenths of the crop, if not a larger percentage, would go to the manure heap if they were not tinned or bottled. It is probably the wastage that occurs with "too many of one season" Pears that leads to the conclusion that from a general utility standpoint the Plum is decidedly more serviceable than the Pear. One of the chief things to consider when planting cordons is to choose the best in their different seasons, starting with, say, Beurré d'Amanlis and ending with Josephine de Malines. E. B. S.

Hardwick.

Well-flavoured Apples.—I agree with everything Mr. Strugnell says about Apples, on page 16, until I come to the expression, "sweet-cooking" Apple. We do not want that at all. Such sweet Apples as one sometimes finds among cider Apples are not the best; we want a pleasantly acid Apple like the Newtown Pippin now on our markets, and also our own best Apples, such as the Ribston or Blenheim. I do not know any Apple I should call a first-class Apple that is remarkable for sweetness. The point is that such Apples as I have named are so fine in flavour that they do not want anything of added sugar. The French Crab is not a sweet Apple, but it is an excellent one for cooking or any other way of eating it. It is much neglected where it grows under various names in different parts of our country, but in the Antipodes they have taken to it, and some very fine samples come to Covent Garden. I think it is the old French Apple, *Pomme de Fer*, which in some way came into Kent and stayed there. Is Reinette du Canada enough thought of among our Apples for cooking, or any other way of eating it?—W.

GARDEN PESTS AND FRIENDS.

SILVER LEAF IN FRUIT-TREES.

(Concluded from page 35.)

ECONOMIC IMPORTANCE AND DISTRIBUTION.—The effect of this disease on the fruit-bearing capacity of a single tree is considerable, but of slow development. Young trees are seldom attacked, and, as a rule, few silvered Plum-trees of less than five years old are seen. The disease usually appears even in a badly-attacked orchard as the trees are coming into full bearing. As the fungus develops the yield of fruit gradually fails and finally ceases as the branches die. Death may not, however, occur for some time. The effect on an orchard taken as a whole is more noticeable but irregular. The trees immediately adjoining the tree attacked are by no means always the next to show disease, and the fact that disease does not spread directly to the adjacent trees shows that the fungus does not travel through the roots or the soil to the next tree. An orchard may therefore present a general appearance of being silvered before all the trees are attacked, owing to a number of affected trees being dotted about in an irregular manner, and it is only when a number of trees in a row are cut back for re-grafting or other purpose that the disease spreads in an epidemic manner. The Victoria and Czar varieties of Plum are, as a rule, most liable to attack, but an extensive enquiry conducted by the Board in the fruit-growing districts of England failed to discover any special susceptibility or immunity of any other variety. The distribution of this disease through England appears to be extensive, and many serious cases are reported from all the chief fruit-growing centres, especially those in which Plum-trees are com-

mon. No district appears to be entirely free from it, and as far as can be judged it is spreading rapidly. According to Pickering the disease first became a serious economic pest during the rainy seasons which were experienced about 1903.

METHODS OF CONTROL.—Many experiments have been conducted with the object of finding a remedy for Silver Leaf, but although occasionally local successes have been claimed, no really effective remedy has yet been found. The explanation of the apparent success may be due to the fact that *Stereum purpureum* was never really present in the affected tree and that the silvering was due to other causes. It has also been shown that some affected trees have recovered without any fungicidal treatment, and even without any treatment at all. Very little reliance can, therefore, be placed on reports of the successful treatment of single trees. Plugging affected trees with sulphate of

branches bearing silvered leaves unless the wound is promptly and effectively closed with a coating of tar. Dead branches should, however, be cut off at once and burned before the fungus has time to develop, and the wound should be closed with tar. (2) It must be remembered that the fungus is to be found considerably further down the branch than the level at which the silvered leaves appear. When therefore an affected branch is broken or is cut off for any reason the wood should always be cut back to a point where no brown stain can be found. (3) Dead wood should never be left lying about in an orchard or garden where Silver Leaf exists. All such wood should be burned on the spot or sawn up and used for firewood immediately. (4) Dead trees should be cut down to the ground, and if for any reason they cannot be grubbed up, the stump should be charred and well covered over with earth. (5)

Garden house with stone roof, Uckfield Park.

iron has been tried. A hole has been bored into the tree, crystals of sulphate of iron have been inserted and the hole closed hermetically. Indecisive results only have been achieved by these means and the process cannot be recommended. No really satisfactory treatment is at present known, that is to say, no treatment which is certain to bring good results without running serious risk of causing damage in other directions. The only useful advice that can be given at the present time is that precautions should be taken to prevent the spread of the disease. (1) It must be remembered that the fungus does not appear on the bark till the branch or tree attacked has been killed, and that so long as a diseased portion of the tree is capable of bearing leaves, even though they may be wholly silvered, it cannot spread the disease. As soon as the branch dies the fructifications of *Stereum purpureum* are liable to appear and under favourable conditions spread the spores of disease. It is therefore unwise to cut off

Suckers should never be taken from silvered trees for purposes of propagation. (6) The practice of cutting back silvered trees and re-grafting them is inadvisable, and may even be a means of spreading disease. (7) There is a persistent belief that disease is spread to healthy trees by pruning them with a knife that has been used for silvered trees. This belief is probably unfounded, but it is better to seal all such wounds with tar, as the bare surface affords an easy opening for infection. (8) The fungus flourishes in damp situations. Any improvement in the drainage of an affected orchard or garden will probably help to prevent the spread of the disease.—Leaflet No. 302, Board of Agriculture and Fisheries.

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. Cloth, medium 8vo, 15s.; post free, 15s. 6d. Of all Booksellers or from the office of GARDENING ILLUSTRATED, 63, Lincoln's Inn Fields, London, W.C.

A GARDEN HOUSE.

This is one of the most artistic garden houses I have yet seen. It is on a little Ivy-clad elevation commanding a good view of the garden, and roofed with pretty old Horsham stone. W.

PLANTS AND FLOWERS.

ORCHIDS.

THE DENDROBIUM THYRSIFLORUM GROUP.

This group of Dendrobiums is a most desirable one for amateurs, the flowers being produced in large, drooping thyrses. They are all of easy culture.

D. THYRSIFLORUM blooms from May onwards and is undoubtedly one of the finest Dendrobies in cultivation. The sepals and petals are white flushed with pink, and the lip is golden-orange. In

D. DENSIFLORUM the flowers are produced in dense pendulous trusses, the sepals and petals orange-yellow, the lip downy and rich orange-yellow. It was introduced about the year 1828 and flowered for the first time in this country in 1830 at Messrs. Loddige's Hackney nursery. In

D. CURYSOTOXUM the flowers are of a rich golden-yellow with an orange-yellow disc on the lip. The variety *suavissimum*, sometimes accorded specific rank, has racemes of rich golden-yellow flowers and a deep blood-purple or maroon blotch on the lip.

D. FARMERI somewhat resembles *D. densiflorum*, the flowers being borne in a similar way, but less dense on the scape. The sepals and petals are pale straw-yellow tinted with rose, the lip deep tawny-yellow.

These Dendrobiums have a comparatively short growing season, and once they begin to grow every encouragement must be given them to make up strong, stout pseudo-bulbs. Soon after the scapes are removed new shoots will appear, and directly these begin to root any repotting must be done. Annual disturbance is by no means necessary or desirable, so when repotting becomes necessary a good lasting medium should be selected. Ordinary pots or teak-wood baskets may be used, and each should be filled to one-fourth of its depth with drainage. The soil should consist of *Osmunda* fibre used in a rather lumpy condition, and a little *Sphagnum* Moss can be incorporated with the last layer. During the growing period the plants should be placed in the warm-house, where the atmosphere is kept moist, and the plants well supplied with water. Shade will only be needed whenever the sun is very bright, and at this stage a light spray overhead will be beneficial. As the pseudo-bulbs reach maturity, which can be ascertained by the appearance of a terminal leaf, reasonable exposure to light and air should be the rule. This must be done gradually, and care must be taken that the plants do not suffer from dryness at the root. With such treatment the bulbs will swell up and become thoroughly ripened, an important factor in the cultivation of Dendrobiums. When this stage is reached the plants will be in a fit condition to undergo their long period of repose in cooler and drier surroundings. An average temperature of 50 degs. to 55 degs. F. will be sufficient, and only enough water need be given to maintain the pseudo-bulbs in a plump condition. This treatment should be continued throughout the winter and until the flower-scapes begin to swell, when a little more water and a few degrees extra warmth may be allowed.

SADOX.

CHRYSANTHEMUMS.

LATE CHRYSANTHEMUMS.

EITHER for using in the greenhouse or conservatory up to and after Christmas or for cutting, the late-flowering Chrysanthemums are of great value. The late kinds furnish us with a large quantity of flowers of medium size under ordinary cultivation. It is not a good plan to aim at obtaining the flowers of abnormal size, as if this is done the chances are that some will come deformed, besides which three or four smaller flowers are infinitely better than one of extra size so far as utility is concerned.

Late Chrysanthemums will do well if all work relative thereto is performed some few weeks later than in the case of the mid-season varieties. Starting, for instance, with the cuttings, these may, it is quite possible, be had nearly, or quite, as soon as those of the others. It is not, however, advisable to put in the cuttings so early; if they are inserted towards the end of January, or even in February, good plants can be had. At that season it will not be possible to strike them in a cold frame except in the mildest of winters. The better way is to put the cuttings under a hand-light in a cool-house, afterwards placing them in cold-frames as soon as struck. The after treatment need not differ (the plants simply being later) from that given to the main stock. I consider the bush form of plant better for late Chrysanthemums than the taller-grown plants. To obtain these, of course, a few stoppings will have to be resorted to. These tops will make useful material for the latest cuttings to supply a stock of dwarf plants in small pots. There is one point which I think is overlooked in the culture of late Chrysanthemums; it is that of commencing to feed them far too early in the autumn; a strong growth is thereby made, which will at times fail to set any buds at all; those buds also which may be thought safe will turn blind or fail to grow as they should do. But little loss will be sustained (if any) by deferring the application of manurial stimulants until the plants are housed. This work need not be done quite so soon as in the case of the main crop, there being no buds susceptible of injury by slight frosts. It is not well to risk the plants out too far into October. If not housed they should at least be so situated as to be within reach of temporary protection should a sharp frost ensue. The tendency before alluded to as regards growing too strongly should be further guarded against by keeping the plants in pots one size smaller than the rest. Full exposure to all the light and air, if needful with early and mid-season kinds, is even more essential for the late ones. When housed less warmth is required; by this I mean that the temperature maintained to keep down injury to the blooms by damping is not at first needed for these late sorts. If frost is just excluded they will be safe enough until commencing to show colour; then a little warmth and a more buoyant atmosphere will suit them better. To facilitate the culture of late Chrysanthemums it is far better to devote a house to them. The plants should not be in any way overcrowded; they should, in fact, have more room allowed them than is given up to earlier kinds, so that the foliage is kept in a healthy condition as long as possible. Disbudding can be done to suit each case, but I do not recommend it to be adopted in a severe fashion. Plants with from 12 to 18 flowers are better than those with three or four as far as utility is concerned, as well as for general effect. H. G.

NOTES AND REPLIES.

Show board for eighteen Japanese Chrysanthemum blooms.—I wish to make a show board to hold eighteen blooms Japanese Chrysanthemums. Would some exhibitor kindly furnish full particulars? In a book on Chrysanthemum culture it is said the holes should be 7 inches apart. Surely the National Chrysanthemum Society has altered this rule, as the majority of varieties sent out during recent years are far in excess of 7 inches diameter.—SOUTH AFRICA.

[The special regulations of the National Chrysanthemum Society provide that exhibitors must have their stands of the following dimensions:—For twelve Japanese blooms the boxes should be 28 inches wide from left to right, and 21 inches deep from back to front, the holes to be 7 inches apart from centre to centre. Stands for six Japanese blooms should be 14 inches wide from left to right, and 21 inches from back to front. A "twelve" board may be used together with a "six" board for exhibiting eighteen blooms. The stands have been increased in size two or three times until it has become a tax on exhibitors that they have not been disposed to acquiesce in. Each change in dimensions involves the purchase or the making of new stands and the boxes in which they are conveyed to the shows. In more recent years the National Chrysanthemum Society has encouraged the exhibition of these large blooms in vases, as in this way the true character and size of the flowers are so much better appreciated and displayed. We agree with you that the boards or stands at present in use are quite inadequate to display the large flowers satisfactorily.]

Chrysanthemum blooms—drooping varieties (Japanese) for exhibition.—Would some exhibitor of Chrysanthemums kindly state what is the rule laid down by the National Chrysanthemum Society regarding the judging of the drooping or reflexed varieties, such as Bob Pulling, Mrs. F. C. Stoop, Miss May Fox, etc.—SOUTH AFRICA.

[The National Chrysanthemum Society has no rules of judging. Judges whose qualifications are undoubted, and who should know the good or bad points of any or every variety they are asked to adjudicate upon, are always selected. Mere size does not count with a good judge, but if size is combined with beauty of colour, and with even and consistent form and freshness, little else need give exhibitors cause for anxiety. Colour, size, form, freshness, and quality generally are the factors that have to be considered in judging Chrysanthemums, and in close competition points are apportioned to each of these factors, and the exhibitor who gets the highest number of points is adjudged the winner.]

Border Chrysanthemums.—For both town and country gardens the border varieties of Chrysanthemums are very useful. During the past few years many new varieties have been raised. If due care be taken in making selections of varieties there need not be any lack of blossom in the borders from August to the end of October. Every year we pay close attention to the plants grown in pots, but I am afraid we do not give similar attention to the border varieties. The old roots are left in the ground too long, manured often enough, it is true, in many cases, but they deteriorate and are not so satisfactory as young plants raised from cuttings, or even from the best parts of divided roots that are lifted and replanted. Some border Chrysanthemums do not produce suckers at all freely, and they include many of the best varieties. Lifting and special treatment of the old stools are the best means of securing suckers suitable for cuttings. When the roots are lifted, carefully remove the old soil and then pack them fairly close together in boxes or on beds in a cold-

frame, surrounding them with rather finely-sifted compost of a light, sandy nature. If the old roots are kept fairly moist, and in a rather close atmosphere, suckers will soon grow; then more air may be admitted with advantage to strengthen the suckers from cuttings in due course.—BOURNE VALE.

Market Chrysanthemums.—I was interested in the note on these (page 742, December 11th). Those who grow flowers at home for decoration may learn a great deal from the grower for market. Undoubtedly the blooms grown are of high merit, because they are not too large, but big enough for filling nearly all kinds of vases, and the plants are so useful in the greenhouse, conservatory, and glass porch, as many of the best varieties are dwarf and of a nice bushy habit. For cutting, amateurs may grow a number of plants outside, lift when the buds have formed, and simply mould over the roots when the latter are placed on the bed of a vinery, Peach, or other suitable house. This plan would admit of more flower pots being used for growing specimens in for conservatory embellishment. For many years I have adopted the following plan with a good deal of success. Instead of putting out the plants in the usual way in borders, for lifting in due course, I put down a ridge of good lumpy compost on a bed of ashes. The ridges of soil were 3 feet apart, 15 inches wide, and about 9 inches deep, the plants being put into the centre of the ridge 18 inches asunder. During the summer, watering and feeding did not entail much labour. In the autumn the plants were lifted by simply placing a garden fork under each one and then transferring them to the glass structure. Very little soil dropped off, and not much was needed over the roots in the house. These plants never suffered through the removal, and flowers were gathered from them as late as the middle of January.—G. G. B.

Outdoor Chrysanthemums.—Will some reader kindly give me a list of about a dozen of the best showy, early, hardy Chrysanthemums for out of doors; not those which do not bloom till October or later, as rain always spoils them here? I want good, clear, decided colours—yellow (light and dark), red, pink, and white. Cranford Yellow was a success one year, and also a really beautiful variety called, I believe, Shower of Gold, but I seem now to have lost both. Hollicot White did well the same year. I also want the names of a few singles in the way of Mary Richardson, a splendid Indian red that is a mass of bloom each year, always reliable, and blooms nice and early. It is, however, too tall, and wants a lot of staking. Are there any in the way of Ladysmith in other colours? I once had a lovely white, Cannell's Paris Daisy, but could never get it again, and it was, though a perfect companion for Ladysmith, apparently much less hardy. Goacher's Crimson sometimes does well and sometimes dies. Is there another as good and less capricious? It appears invariably fatal to move them if they once do well, yet they make such great clumps. Disturbance cost me all those mentioned above as successful.—M. L. W.

Chrysanthemum Scur Melanie.—A good batch of this old variety is of some value in early December, alike for the conservatory and for cutting. It forms an attractive contrast to the somewhat gaudy *Salvia splendens*, at its best at the same time, and good bushy pieces full of bloom can be grown in 6-inch and 7-inch pots. A good quantity can be grown with a minimum expenditure of time and trouble from cuttings struck in February and March. These are planted out during May in a prepared bed in the open, stopped once or twice, and lifted and potted towards the end of September.

OUTDOOR PLANTS.

CLEMATIS DURANDI.

This excellent hybrid is free, bold, and good in colour. I have grown it for several years, and always with good results. It is happy on Oak trellises, and also over bushes. W.

— When the Jackman hybrids of Clematis came into existence popular favour was at once directed to them, with the result that the old species fell into neglect and could only be found in botanical collections. Among them was *C. integrifolia*, introduced in 1596 from Central and Southern Europe. The illus-

This short note describes well the spray of bloom figured to-day. It differs from *C. integrifolia* by its somewhat taller growth, broader and more massive leaves, and larger flowers. In *C. integrifolia* Durand we have a fine hardy plant which deserves more attention than it at present receives. Many other hybrids of *C. integrifolia* have been raised, but *C. i. Durandi* is, without a doubt, the finest of them all.

AMONG THE HARDY FLOWERS.

SEED-SOWING.—There is great gain in raising one's hardy flowers from seeds. This is specially desirable when novelties

there is a great danger that the young seedlings may become drawn and weakly from want of light and air and from too much heat. I am speaking from experience, and, besides these dangers, there is always the long period of care they require before the seedlings can be put out with safety. The end of February or the beginning of March is quite soon enough for sowing.

PRIMULA COCKBURNIANA.—It is strange to find such a difference of opinion about the biennial or perennial duration of *Primula Cockburniana*. Some of my friends assert that it is a true perennial, and others maintain that it is a biennial. With some it is a biennial only, but others

A flowering shoot of Clematis integrifolia Durandi.

tration we give to-day of one of its progeny is a revelation to those who are unaware of the existence of a non-climbing, herbaceous Clematis, with flowers nearly as large as those of many of the present-day hybrids, and in colour of the first water. The first record of the hybrid *C. i. Durandi* appears in the pages of *The Garden* of April 25, 1874. It is recorded that:—

MM. Thibaut and Keteleer announce under the name of *C. integrifolia de Durand* a new hybrid between *C. integrifolia* and *C. lanuginosa*. It grows 4½ feet high and bears dark, velvety flowers, each from 3 inches to 4 inches across, with yellow stamens. It blooms continuously from May till October.

are offered, as seeds are generally cheaper per packet than a single plant of the new flower. Then we often have these novelties in plants sent out of very small size, and calling for a considerable amount of coddling before one can consider them out of danger. For the price of one, or even for less, we may have a number of plants, and may make a nice clump or group if we so desire. It is true that we have sometimes to wait longer for results, but, on the whole, the balance of gain is largely on the side of raising the plant from seeds. Those who have greenhouses or other heated glass structures often think they will gain a great deal by sowing their seeds of hardy flowers as early as January. A little time may be gained, but

can keep it for several years. I think that thorough drainage is very helpful, and that removing the flowers so soon as they are over has also a good effect. Yet I do not venture to dogmatise, and am always willing to profit by others' experience.

PRIMULA SINO-LISTERI.—I should be glad to know if I might venture to leave this outside with impunity. It comes so near to *Primula obconica* that I am doubtful of the wisdom of doing so. If it is not hardy I shall keep it in a pot and plunge for a time in the open, or lift it and pot it in winter.

THE WOOLLY THYME.—Thymes are favourites of mine, and among the few that I grow I always appreciate *Thymus*

VEGETABLES.

WORN-OUT SOIL.

To renew a worn-out garden soil to a state of thorough fertility demands a deal of forethought and knowledge on the part of the individual in charge. Even in these days of high-class gardening it is no uncommon thing to meet with gardens the soil of which is completely exhausted through being long cropped with the same things and manured with the same material for years. The soil in such cases gets sour, and in time becomes a hotbed of weeds and vermin. Such cases more frequently occur on thin soils than on deep land of a clayey nature. Nothing is more productive of satisfaction to the good all-round gardener than a good kitchen garden, and if he has aspect and suitable shelter to husband the warmth of the sun's rays he has in a measure in his own possession the making of the soil.

To deal effectively with such cases as are indicated, no half-and-half way of doing the work need be thought of, and whatever is worth doing is worth doing well, however tedious and laborious the work may be before being accomplished. Now is the time to have all unoccupied ground turned up to get the winter's frost and air to sweeten and pulverise it. To improve a poor soil thoroughly something more than the ordinary orthodox system of trenching is necessary; every trench ought to be 2 feet wide, and turned clean over to the depth of 2 feet, if there be surface-soil to do that with, being careful to put the surface part with all its weeds and vermin into the bottom on the top of the subsoil, which should be broken up at least a foot deep. The more vegetable matter that can be turned into the bottom of the trenches the better, and the surface should have a good dressing of lime and soil, than which little better can be got to enrich poor ground. If such a course were year after year followed until the whole garden was gone over, a poor worn-out soil would soon be productive of good results, and in all likelihood it would take four or more years before the whole could be gone over, according to the size of the garden. One particular point in trenching should always be borne in mind—viz., the more vegetable refuse that can be put into the bottom of the trenches the better, as it acts beneficially in many ways, supplying food for the roots in a dry season, and also keeping them from going into the cold subsoil. It was my lot many years ago to enter upon a garden the deep cultivation of which had been so neglected that it would scarcely grow anything satisfactorily. It was impossible to expect much from the mode of cultivation that had been adopted—that of digging rank manure into the surface, that kept the free, light soil so open, that whenever the dry weather set in in June there was an end to the appearance of good crops. Deep cultivation was adopted in the manner stated, and the result was that vegetables were both abundant and wholesome. K. S.

Useful frame Carrots.—Those who value the small, sweet, tender Carrots which are such a feature in the Paris market will do well to make a sowing at once, on a mild hotbed, of the Inimitable Forcing Carrot, a globe-shaped variety with a clear skin, and one of the quickest to mature we have. The plants should be grown near the glass, and by using leaves in the making of the hotbed I have found one gets better roots, as the leaves remain in a moist, warm condition, which the roots like, while little watering is required; indeed, the less the better. If a larger root is liked there is no lack of good

varieties—such as Early Gem and Early Nantes—which require more time and make a good succession to the Inimitable Forcing. Given ordinary cold-frame culture, or sown on a warm border in February, and sheltered by mats or covers of some kind, such as spare lights, to protect from excessive rainfall, a much earlier crop, and at a season the roots are valuable, will be obtained.—F. K.

Potato Dover Castle.—Last season this proved an excellent introduction, and though the amateur is often at a loss when selecting a new variety or making a change of seed, I feel sure he will not regret trying this. Introduced in 1913, there has been sufficient time to test its merits. Though quality should be the first point, it is essential that the crop should be satisfactory also. In both respects Dover Castle will be found all one may desire. It is a late variety, and, grown in loamy soil, was the last to mature. Doubtless in lighter land and well drained it would be a little earlier. The tubers are kidney-shaped and handsome, with very shallow eyes, therefore there is no waste. There was no disease, and at this date (December) the quality is all one may wish. The plants make a close, compact growth, and the flowers are white. For many years Windsor Castle was a great favourite for its quality. Dover Castle may be classed as a later form of that well-known Potato.—W. F.

A useful winter salad.—With such variable weather as we have had this season the outdoor Lettuce crop has been destroyed in many gardens, and in others so much injured that the plants will take a long time to recover. The excessive rainfall has done more injury than frost. For many years, with a short Lettuce supply in mid-winter, I found it a good plan to get tender, delicate salad, to sow Lettuce seed rather thinly in boxes, much in the same way as Mustard and Cress, using a white Cos for preference. The seeds, if placed in a warm-house, and when germinated stood close to the glass, will give excellent cutting material for the salad bowl. If not given too much moisture the seedlings remain good a considerable time. It is advisable to thoroughly moisten the soil before sowing. Do not place much soil over the seed; indeed, I merely press in the seed with a flat board. Use good soil of a light nature. If sowings are made fortnightly there will be a supply of excellent salad material.—W. F.

Early Cauliflowers.—When nice, fresh Cauliflower-heads can be had about the first week in June they are most acceptable, and now that we possess so many early sorts that need not be difficult. The old plan of sowing in August or September, and keeping the plants under glass during winter, entail a great deal of labour, and therefore I have ceased to follow it, and now sow in spring. If seed of some of the earliest sorts is sown now in gentle heat the young plants will appear in a week, when they may be grown slowly on until the end of March, and then they should be planted out. If kept near the glass, and not allowed to become too crowded, they will be found to be much more healthy and robust than plants raised in autumn and wintered under glass.—N.

New Index and Binding Cases for completed Volume.—The Index to Volume XXXVII. of GARDENING ILLUSTRATED is now ready (price 3s., post free 3s.). The Binding Case for the same volume is also available (price 1s. 6d., by post 1s. 9d.). The Index and Binding Case can be obtained from any newsagent, or from the Publisher, 63, Lincoln's Inn Fields, London, W.C. If ordered together, the price of the Index and Binding Case is 2s., post free.

lanuginosus. It does not flower so well as the others, but, on the other hand, it forms such a spreading cushion of a pleasing tone of grey that I admire it every time I see it. I have been told that plants with woolly leaves are liable to suffer greatly in wet winters, but I do not find that this is the case with *Thymus lanuginosus*. It never looks back with me, and yearly grows in size unless cut back lest it should encroach too much upon the domains of its neighbours. It is a delight when it is hanging over the stones of a rockery. A nurseryman told me the other day that some of his customers find it most difficult to establish, and buy plant after plant before they succeed. Some, indeed, give it as "too fastidious," which is rather a libel. It certainly likes a dry soil and stones about its roots. As a carpenter it is excellent, but should only be used for the more vigorous bulbs, such as Daffodils, and not for choice Crocus species.

SAXIFRAGA SIBTHORPI.—This bright, golden Rockfoil seems much the same as one I see grown as *Saxifraga Cymbalaria*. It is a nice little plant with shiny, light-green leaves, and begins to flower when the plant is only an inch or two high. It gradually extends its flower-stem and blooms for a long time, eventually becoming as much as 6 inches in height. I like it best when it comes first into bloom, as then the wee golden flowers seem as if set close on the small and pretty leaves. It flowers in spring and goes on for a long time. It is only a biennial or annual, but it seeds and sows itself in a most lavish way, so that we need never trouble to sow it unless we want it in any special place. It has a habit of growing well in one place for a few years and then taking a fancy to migrate gradually to "fresh fields." It evinces with me a preference for a shady and rather moist place, and it settles down there much better than in a sunny, dry position. It looks nice in the crevice of an old Moss-grown retaining wall in the shade, the leaves and flowers being charming for their setting of mossy green.

AN AMATEUR OF HARDY FLOWERS.

NOTES AND REPLIES.

The change of spirit in gardening.—No one can fail to have been struck with the change which has come over the planting out of borders. It will be within the recollection of a good many readers that once it was regarded as the correct thing to have borders filled with scarlet-flowering Pelargoniums, yellow *Calecolarias*, *Perilla nankinensis*, blue *Lobelia*, and yellow *Feverfew*. These were regarded in many quarters as ideal tenants, and if borders were so filled they were considered quite complete. The bulk of this style of gardening has gone. Few, I venture to say, would wish to go back to those days. Many who once looked upon hardy perennials with an amount of prejudice have come to regard them as indispensable in a garden. Why? Simply because an abundance of charming flowers may be had at many seasons, and they give little trouble once planting has been done; besides, once the initial expenses have been borne they can be propagated by root division quite easily. Some of the hardy biennials, which can be treated practically as annuals in regard to raising, are exceptionally beautiful, and great helps to those whose desire is to have the garden beautiful for the longest period. Amongst annuals, too, how delightful to have patches of Sweet Sultan, *Nigella*, Poppies, *Phlox Drummondii*, etc. Hardy plants provide us, too, with much autumnal splendour.—W. F. D.

TREES AND SHRUBS.

HYDRANGEA QUERCIFOLIA.

This plant comes from Florida, and is, therefore, only half-hardy, but will succeed in the open where the ordinary Hydrangeas grow. When in blossom it is covered with its bunches of white sterile flowers, which form a pleasing contrast to its green Oak-leaved foliage. It prefers warm, light, rich soil, with protection against winds and slight protection against the direct rays of the noonday sun. It is easily transplanted or divided.

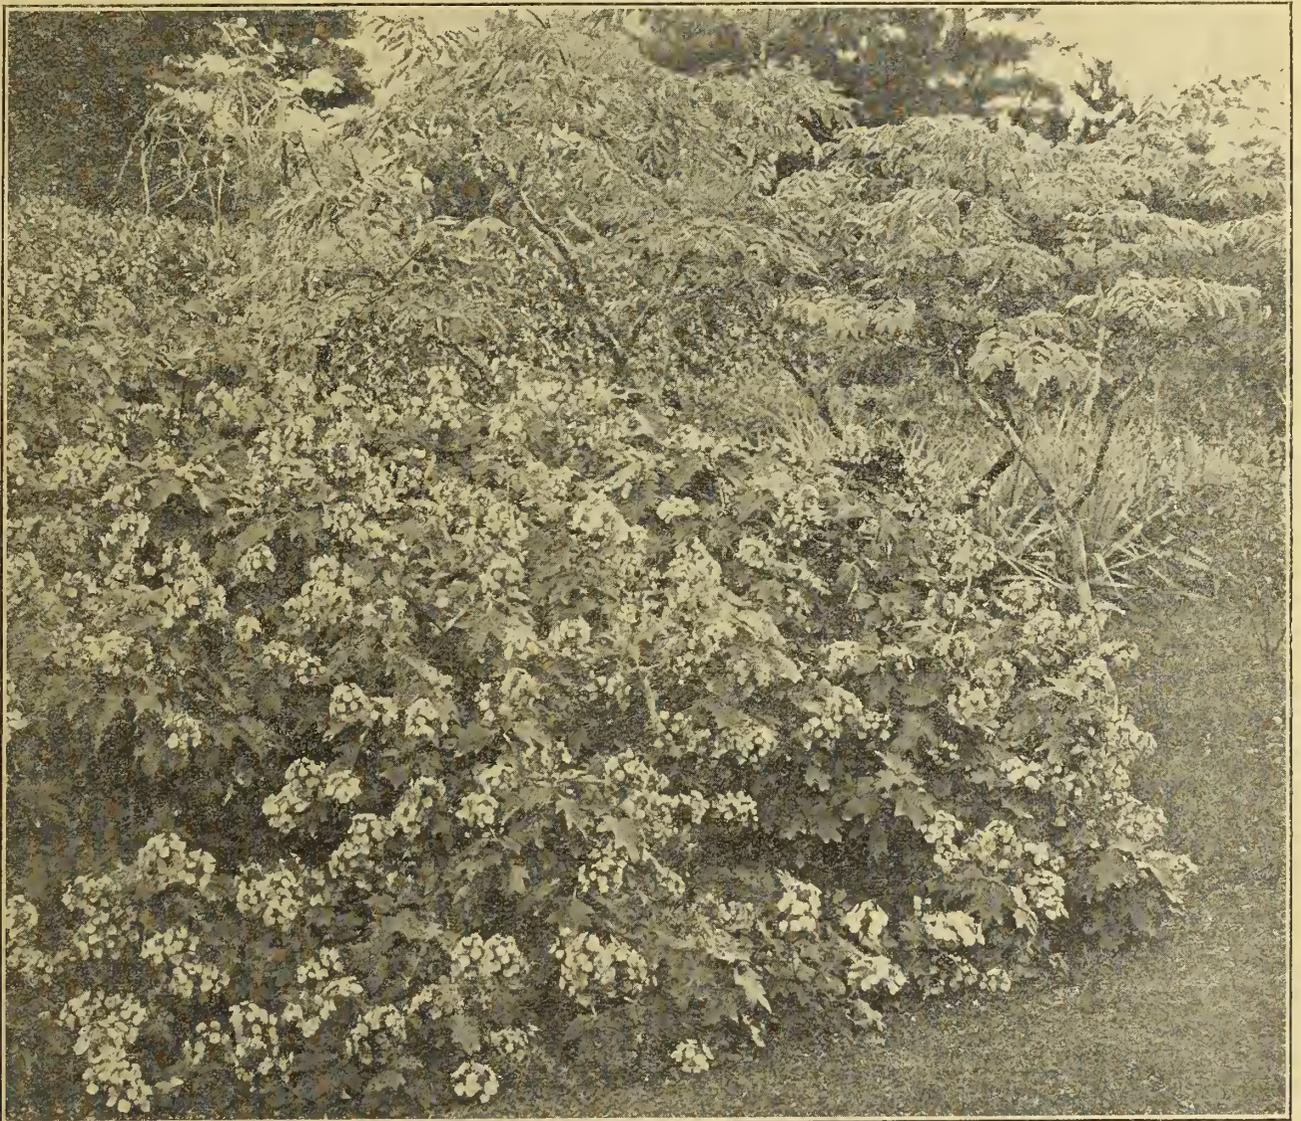

R. H. BEAMISH.

Ashbourne, Glounthaune, Co. Cork.

height being more suitable than larger specimens. It is also advisable to plant early, autumn or early winter being preferable to late spring except in districts where drought is not experienced in early summer, for those plants put in during autumn or winter have an opportunity of becoming well rooted before a dry time is likely to occur. During the first year or two after planting it will be necessary to check the growth of coarse weeds two or three times during summer, but afterwards the plants will look after themselves. As a rule it is advisable to dig or fork the ground over before planting, particularly when it is covered by coarse Grass, but when the ground is very

ing the tops off annually after flowering the plants can be kept quite dwarf if it is so desired. The variety sulphureus, or the Moonlight Broom as it is called, can be used for the same purpose. This should be grown from cuttings and planted out from pots. C. s. Andreanus can also be utilised, but for semi-wild or wild places the type is the best. Where a tall-growing shrub is desired *Colutea arborescens*, the Bladder Senna, can be used, as also can *Caragana arborescens*. Both are yellow-flowered shrubs and are best raised from seeds sown on the spot. They have been used effectively on old heaps near collieries. The

COMMON GORSE (*Ulex europæus*) is

Hydrangea quercifolia in Mr. Beamish's garden at Ashbourne, Glounthaune, Co. Cork.

SHRUBS FOR DRY BANKS.

It is sometimes difficult to deal successfully with dry, sandy, or gravelly banks so as to clothe them at small expense with vegetation of a permanent character, and that will grow with the minimum amount of attention. Beyond the limits of the garden, too, it is sometimes necessary to plant a hill-side, particularly when extensive bare areas are exposed to view from the windows of the house.

It is usually advisable to sow seeds and let the seedlings fend for themselves from the start, but it is possible to plant out seedlings or rooted cuttings from pots, or small plants from the nursery. In most cases, however, small plants are preferable to large ones, those below 9 inches in

steep, and likely to be washed by heavy storms, it is better to cultivate small patches, leaving grassy spaces in between; then, in a few years, after the plants have become established, dig up and plant the remaining areas. This will prevent the surface soil being washed away. The

COMMON BROOM (*Cytisus scoparius*) is one of the best plants for poor soil, and there are few places in the country where it cannot be established. Seedlings of a few inches high can be transplanted successfully, but larger plants may fail. If in February, however, seeds are sown thinly over loose ground and raked in, or two or three seeds are dibbled into the ground at distances of a foot apart, seedlings will appear in due course. By mow-

another excellent bush for poor soil; it should be sown direct on the site or planted from pots. An even better plant is the double-flowered variety, for it is more compact in habit, and after flowering has a tidier appearance by reason of the absence of seed-pods. This, however, can only be raised from cuttings, and must be kept in pots until planted permanently. Cuttings of half-ripe shoots, 3 inches to 4 inches long, inserted in a bed of sandy soil in a cold frame in July or August, usually root by the following April, when they may be taken up and potted singly. As a rule the poorer the soil the better the results. An autumn-flowering Gorse is obtainable in

ULEX GALLI, a low-growing bush often

of compact habit, and not more than a foot high. It blooms finely in September and is very effective when associated with common Heather (Erica cinerea) and Ling (Calluna vulgaris), both of which can be established on poor soil, although less rapidly than Gorse and Broom. It is usually advisable to take well-rooted plants from nursery beds and plant them 12 inches to 18 inches apart. In the event of dry weather being experienced during the first year or two it is a good plan to scatter decayed leaves between these Heaths in order to preserve moisture in the soil. The

COMMON JUNIPER (*Juniperus communis*) is another excellent evergreen for dry places, particularly in chalky districts, whilst the prostrate forms of *J. Sabina* can also be used. For the milder part of the country the various species of *Cistus* are excellent for sunny banks, and, as a rule, they give quite as good results in sandy soil as in soil of good quality, growth being less soft and consequently better ripened in the poorer soil. A few good ones are *C. laurifolius*, *C. populifolius*, *C. albidus*, *C. florentinus*, *C. monspeliensis*, *C. Loreti*, and *C. corbariensis*. The first-mentioned grows from 4 feet to 6 feet high, the others varying from 1½ feet to 4 feet in height. The *Helianthemums* may also be used, particularly the numerous forms of *H. vulgare*. Where a tall-growing plant is required,

SPARTIUM JUNCEUM, the Spanish Broom, can be used, whilst *Genista virgata*, a large bush, sometimes 12 feet high, is an excellent plant for an open position or for semi-shade. The various wild Roses can often be established in poor soil, particularly the Scotch Rose, *Rosa spinosissima*. This can even be used with effect on sand dunes near the sea, where, although it may be hut an inch or two above the sand, it blooms with the greatest freedom. The Blackthorn (*Prunus spinosa*) and Way-faring Tree (*Viburnum Lantana*) can be established on hill-sides where chalk is near the surface, as well as in other places, whilst the Double flowered Bramble (*Rubus ulmifolius flore pleno*) can be established if planted when small. Where a few inches of good soil are found in a garden, or where a little good soil can be provided, Lavender can be established, whilst *Berberis stenophylla* gives good results in places where a large, free-growing evergreen is desired. When neither of the plants mentioned can be obtained the Irish Ivy can be tried, whilst that good-natured evergreen, *Berberis Aquifolium*, can also be planted with good results.

Amongst trees, three of the best for poor soils are the Scots Pine, Common Birch, and Mountain Ash. D.

Newer Lilacs plant now.—Where there is plenty of the older Lilacs it is well to introduce a few of the newer varieties, for in size and colour of flowers they are improvements. Where flowers are wanted early, and there is warmth, it will pay to pot up any plants with good strong buds. They may be started in the Mushroom-house and afterwards moved to the light.—E. II.

***Distylium racemosum*.**—This, one of a number of curious shrubs belonging to the Hamamelis, is less beautiful than the various kinds of Hamamelis, but worth growing in the milder parts of the country in those gardens where interesting and out-of-the-way shrubs are encouraged. A native of Japan, it is in that country of tree-like proportions, but here it is no more than a shrub. Its evergreen leaves are Willow-shaped. The flowers, at their best in late spring, are chiefly remarkable by reason of their bright-red stamens. It requires light loamy soil to which a little peat or leaf-mould has been added, and should be given a position sheltered from cold winds.—D.

INDOOR PLANTS.

NOTES AND REPLIES.

Clematis indivisa failing.—The enclosed leaves are from a *Clematis indivisa* I have in my cool greenhouse. It is growing remarkably well, and new shoots appearing, but after a very short time the leaves turn like these. I have used sulphide of potassium, but it seems to have no effect. What would you recommend me to do?—CORNWALL.

[If the atmosphere of the structure in which *Clematis indivisa* is growing is at all close and moist the leaves are particularly liable to be attacked by mildew, as has happened in your case. We have found the best check to be dusting the foliage with sulphur, but by far the most important point is to see that there is a free circulation of air throughout the structure in which the plant is growing. During such a spell of damp weather as we have experienced of late mildew will, of course, be more troublesome than if the weather is dry.]

Erythrina Crista-galli.—This good old flowering plant has been shown in fine condition at some of the meetings of the Royal Horticultural Society during the present season. Some of the species are among the showiest of tropical trees, but, as a large structure is necessary for their development, they are very rarely seen. On the other hand, *E. Crista-galli* may be readily accommodated in a limited space, and during the summer it will grow and flower well out of doors. *E. Crista-galli* forms a thickened root-stock, whence annual shoots are produced. These, which reach a height of 4 feet to 6 feet or thereabouts, are furnished more or less with spines, and clothed with handsome foliage. The flowers, which are borne in large terminal racemes, are of a deep red colour, thick wax-like in texture, and of a singular shape. In a snug corner, such as in the angle of two glass structures, this *Erythrina* will pass the winter without injury, provided the root-stock is protected from frost. It is propagated from cuttings of the young shoots taken in the spring and placed in a close propagating-case.—W. T.

Hibbertia dentata.—This is one of the best of greenhouse climbers, flowering during the first three months of the year. It is of moderate growth, and mounts upwards by entwining its slender shoots around any support. The leaves are, when mature, of a deep olive-green, but in a young state they, as well as the growing shoots, are of a bright crimson tint. The flowers, which are each about 2 inches across, are bright yellow, and in general appearance very suggestive of those of a *Hypericum*. Being freely borne they are very effective when nestling among the deeply-tinted foliage. Throughout the summer, when growing freely, the foliage is particularly attractive. This *Hibbertia* will strike root readily from cuttings, while in a greenhouse I have had it seed freely. A singular feature was noted in connection with the seeds, for sown directly they were ripe some of them germinated at once, while the others lay in the ground for nearly a year and then grew.—K. R. W.

***Lilium Krætzeri*.**—There are many varieties of the popular *Lilium speciosum*, but it is safe to say that none of them is so handsome as the subject of this note. Many who grow *L. s. album* imagine that they have secured the best white, but they will find that this Lily is occasionally faintly tinged with pink, while the mid-ribs of the petals are of a decidedly pinkish shade. *L. Krætzeri* is free from this drawback, the large, handsome, and well-shaped blooms being absolutely white. In this case, the mid-ribs of the petals are of an attractive shade of green, which emphasises the whiteness of the bloom. For Christmas or at Easter, when white flowers are in request, nothing is more serviceable than *L. Krætzeri*.—KIRK.

ROYAL HORTICULTURAL SOCIETY.

JANUARY 11TH, 1916.

The first fortnightly meeting of the year was held on this date, and, whether regarded from the standpoint of quantity or quality or both combined, may safely be stated to be the finest January exhibition ever held in the hall. The bank of Orchids from Haywards Heath would have done credit to a big Chelsea meeting, while the Cyclamens from Reading were among the best ever presented at this season. In other directions, Carnations were particularly well shown, while the earliest alpiners were, perhaps, seen in larger numbers than is usual at this time.

HARDY PLANTS.

Quite a surprising lot of these was presented, and in unusually good form, the latter due unmistakably to their having been sheltered in cold-frames, which, while preserving the flowers, do not destroy their character. Of these, one of the most interesting was that staged by

Messrs. Barr and Sons, King-street, Covent Garden, W.C., in whose varied collection the most useful item was a goodly batch of *Iris unguicularis*, so long known as *I. stylosa*. Equal to the choicest Orchid in delicate beauty, it possesses the additional merit of hardiness, and may be enjoyed by all. Other items of interest were the winter-flowering Croci, of which *C. chrysanthus* and *C. Imperati* were noticeable. Coloured Primroses and Lenten Roses in variety were also included in the group.

Mr. Clarence Elliott, Six Hills Nurseries, Stevenage, brought a beautiful and well-flowered batch of the best of Burser's Saxifrage (*S. B. Gloria*), which, in the open without protection, was in full bud three weeks ago. The handsome white flowers on reddish stems, each 2 inches high, were very good. *S. Boydi alba* (of robust growth and free) and *S. Irvingi* (almost a pink-flowered *Burseriana* and a good addition) were remarked among others.

Messrs. Whitelegge and Page, Chislehurst, had a considerable showing of alpine plants in pots—largely Saxifrages. These included well-flowered batches of *S. apiculata*, *S. Boydi alba*, *S. Salomoni*, *S. Elizabethæ*, and a particularly good lot of *S. Burseriana*. The fine blue *Lithospermum rosmarinifolium* was welcome and good.

Mr. G. Reuthe, Keston, arranged a collection of alpiners and shrubs, the former, chiefly Saxifrages in flower, having been practically cleared by mice during a night at the station. Of such as *S. Boydi*, *S. Kestoni*, *S. Haagei*, and *S. Griesbachi* a few only remained in flower.

Mr. J. J. Kettle, Corfe Mullen, Dorset, put up a lovely lot of Violets, which he grows and shows so well.

Mr. Herbert Chapman, Rye, exhibited pots of his new hybrid Trumpet Daffodil *Reveille* (*pallidus præcox* x *princeps*), which had come into bloom thus early in a cold-frame. As shown, the new-comer is virtually a pale-coloured *princeps*, below the latter's average size. It is graceful and free, and is said to be a good garden variety. Pots of hybrid and other Snowdrops also came from the same source.

GREENHOUSE PLANTS.

Messrs. Sutton and Sons, Reading, contributed a full length table of Cyclamens, the pick of their famous strains of these indispensable winter flowers. Arranged in circular baskets, one colour in each, and brilliant or pure in colour, they constituted a considerable attraction, and were much admired. Particularly effective

tive was the Silver-leaved Salmon, a variety worth cultivating for foliage alone. Others of striking individuality were Salmon Scarlet, Giant White, Giant Crimson (the last two the largest-flowered of the race), Vulcan (intense crimson), and White Butterfly (one of the purest). Associated with fresh Ferns and backed by Palms, the group was most effective.

Messrs. H. B. May and Sons, Edmonton, also displayed an excellent lot of Cyclamens, arranging the plants in groups in red, white, salmon, pink, and other shades in a setting of greenhouse and hardy Ferns, the latter chiefly evergreen Scolopendriums, which alone are most welcome at this season. A good background was formed of Kentia Palms.

SHRUBS.

The most interesting item under this head was a fine cone-bearing branch of the South Californian *Abies bracteata*, sent by Lieut.-Col. Barclay, Bury Hill, Dorking (gardener, Mr. Grayswark), taken from a tree nearly 70 feet high, and having a spread of 36 feet. The branch shown was full of cones, each 3 inches to 4 inches long, and ornamental in the highest degree. Regarded generally as somewhat tender, it is suited to planting in favoured localities only.

Messrs. J. Cheal and Sons, Crawley, showed selected examples of white and red flowered *Mezereum*, the blooms much larger than usual. A spray of the Winter

doubt, it ranked among the finest ever staged at a January meeting. Space will not admit of our entering into details of the many choice kinds staged, and it must suffice to say that the group teemed with delightful forms of *Odontoglossums*, both white and blotched varieties, was rich in *Laelias*, *Laelio-Cattleyas*, *Odontiodas*, *Miltonias*, *Cymbidiums*, and *Calanthes*, while beautifully-coloured examples of *Sophranitis grandiflora* afforded a bit of brilliant colour possessed by no other Orchid at any season. Several dozen well-flowered examples of the chaste *Masdevallia tovarensis* also found place in the group, and rarely have better examples been seen. A gold medal was awarded this fine display. Several other small collections of Orchids were staged by leading growers.

A list of the certificated plants and medals awarded will appear in our next issue.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM JANUARY 6TH.—*Winter Sweet* (*Chimonanthus fragrans*), *Berberis japonica*, *Garrya elliptica*, *Daphne Dauphini*, *Daphne Mezereum*, *Jasminum nudiflorum*, *Coronilla glauca*, *Andromeda floribunda*, *Hamamelis arborea*, *Laurustinus* (various), *Strawberry-tree*, *Parrotia persica*, *Erica herbaacea carnea* (in several varieties), *E. mediterranea glauca*, *E. m. hybrida*, *E. alpina*, *Tree Ivies*, *Genista hirsuta*, *Polygala Chamæburus purpurea*, *Prostrate Rosemary*, *Snowdrops* (in variety), *Violets* (in variety), *Crocus Imperati*, *Aubrietias*, *Tufted Pansies*, *Polyanthus* (in variety), *Christmas Roses*, the *Corsican Hellebore*, *Cyclamen Coum*, *Winter Heliotrope*, *Primroses*.

WORK OF THE WEEK.—The pruning of climbing plants has been continued, as this is possible so long as the weather is fine overhead. When planting is stopped owing to the sodden state of the ground, pruning can be pushed along. *Ceanothus* on walls are cut back to three eyes or four eyes, and old worn out wood removed. The *Winter Sweet* (*Chimonanthus fragrans*), being in bloom, is left alone for the present, but will be reduced somewhat after flowering. *Actinidia arguta*, usually makes a lot of strong training growths, and these, if not required for furnishing bare spaces, are cut back to six eyes. *Actinidia Kolomitka* requires very little attention, most of the wood made being short, stubby spurs, with an occasional trailing growth. This is a lovely climber for warm south walls, where it flowers annually. *A. chinensis* is a rapid climber, in its element when rambling through an old tree. *Clematis orientalis* is a very strong grower, and it is necessary to cut it back hard each year, also some of the old wood is removed. *Solanum crispum* (Glasnevin variety) is spurred back each year and a little of the old wood removed to allow the sun to play freely among the branches. Some old plants of *Rhododendron ponticum* have been grubbed up and the ground replanted with *Crataegus macrantha* and *Rhododendron Cunningham's White*. The clearing of leaves from the carriage-drive has occupied considerable time, but the material collected and the improved appearance will repay the time expended on such work. A border has been well prepared and planted with a large number of *Christmas Roses*. Hitherto these have been grown where they were shaded for the greater part of the day, but in that position they were not a success, being subject also to the drip from overhanging trees. Lime, sand, and a large amount of

Ferns and *Lilium auratum* in the greenhouse.

Messrs. Allwood Bros., Haywards Heath, showed winter-flowering Carnations very finely, the examples, whether for quality, fulness of bloom, or brilliant colouring, practically equal to those produced in late spring. We thought the vases of *Bedford Belle* (reddish-salmon) most effective. It is also fragrant. *Champion* (scarlet), *Wivelsfield White*, *Bishton Wonder*, *Fairmount*, and *Mikado* were good. There were also some good white and yellow ground fancies.

Messrs. Stuart Low and Co., Enfield, also had a capital group of these flowers, some of the best varieties being *Mrs. Mackay Edgar* (a fine salmon-pink), *Britannia Improved* (very rich scarlet and full flowers), *Baroness de Brien*, *Gorgeous*, *Pink Sensation*, and *White Wonder*.

Sweet (*Chimonanthus fragrans*) was among other fragrant subjects. *Garrya elliptica*, well-flowered examples of *Jasminum nudiflorum* (of richer colour than usual), with *Erica arborea alpina*, and *E. carnea* were noted among others.

Mr. L. R. Russell, Richmond, arranged a table of *Ivies*, *Aucubas*, and a variety of useful evergreens.

ORCHIDS.

The outstanding feature of the meeting was a magnificent bank of Orchids arranged by Messrs. Charlesworth and Co., Haywards Heath, the group extending from the entrance to the Orchid annexe. Rich in beauty and variety, the group also showed the wealth of the Orchid family at this season of the year, since, without

decayed leaves were well incorporated with the soil to keep it porous. A few others have been put out among summer-leaving Ferns. A group of *Skimmia japonica* has been planted to fill a corner previously occupied by Christmas Roses. Some good plants of *Rhododendron Thomsoni* having come to hand a place has been found for them where they will be protected from east winds and partly shaded by old Scotch Fir-trees. A small batch of *Azalea Kämpferi* has been added to the *Azalea* garden, near the edge of which have been planted a few roots of *Ranunculus amplexicaulis*. A large group of *Geranium ibericum* has been transferred from the garden to the waterside, where it is planted in the Grass.

Sussex.

E. M.

SOUTHERN COUNTIES.

Salvias.—These being now past their best will be thrown away with the exception of half-a-dozen plants of each variety—viz., *Fireball* and *S. splendens grandiflora*, which will be retained for stock and stood where the temperature does not fall below 50 degs. If placed in a cold house the plants invariably perish.

Cinerarias.—As *Chrysanthemums* are now practically over their places are being filled with the most forward of the *Cinerarias* of the *stellata* type, which will shortly make a fine display. Manure and soot-water are afforded them alternately. Later-flowering batches of plants are fumed occasionally to keep them free of aphid, while feeding at the roots, now that all are pot-bound, has daily attention—*i.e.*, when water is required.

Pelargoniums.—The earliest lot of plants to flower has been re-arranged and given more space, as they are now growing apace. They will be stopped again, after which they will be allowed to grow away and bloom. A batch of younger plants to flower later is making sturdy growth on a shelf close up to the roof glass. They are now in 4½-inch pots, but will shortly be shifted into others two sizes larger, in which they will be allowed to bloom. Frequent fumings are necessary to keep green-fly at bay. To avoid fuming the house simply for them alone the plants are removed for the night to another house, the occupants of which need a fuming, and taken back next morning.

Marguerites.—Plants of both the single and double varieties which were struck in autumn are now rooting freely in the pots to which they were transferred from the cutting pots a few weeks back. They will now be cut back to from three to four leaves from the base, with the object of forming dwarf, bushy plants. When they show signs of breaking they will be given a final shift into 6-inch pots.

Propagating.—Before the propagating-case is required for the rooting of soft-wooded bedding plants it will be utilised for striking a batch of Perpetual-flowering Carnations. Directly these are rooted the propagating of various stove plants will be proceeded with; also of subjects such as *Panicum variegatum*, etc., for draping the edges of stages. The Carnations will be inserted in pans filled with pure sand, but the cuttings of stove plants, such as *Crotons*, *Dracenas*—with the exception of *D. Sanderae*, of which four and five are dibbled into each pot—*Pandanus Veitchi*, and so forth, will be inserted singly in small pots filled with suitable compost, a pinch of sand being placed at the base of each to hasten the callusing and subsequent rooting. *Gardenias* and plants of a similar nature strike best when the cuttings are inserted round the edges of 7-inch pots. Before being used the case has to be thoroughly cleaned and made

insect-proof, otherwise crickets are apt to get inside and work mischief among the cuttings, particularly of Carnations, which they will eat off wholesale. Pit sand or fine ashes is the best material for placing in the case in which to plunge pots, etc.

Poinsettias.—As the bracts are now fading the plants will be removed to a house where a temperature of 50 degs. to 55 degs. is maintained. Here they will be placed under the stage to undergo the necessary season of rest.

Strawberries.—Weeds at one time in the autumn almost gained the upper hand, but by dint of perseverance in the way of hoeing and hand-weeding they were eventually got under to an extent that none but very small specimens were left. Thanks to the abundant rainfall and the mildness of the weather these have made much growth of late, and if not dealt with will soon prove a nuisance. Although not advocating the practice of digging between Strawberries, there is no alternative on the present occasion but to do so, and the weeds will therefore be pointed in together with the manrial mulch applied in September last. By doing this now it is hoped that the loss of roots which will follow will be amply compensated for by the pushing out later on of myriads of new roots into the buried manure. So far there has been but little loss of old foliage, but such as has succumbed will for the present be allowed to remain on the plants for the protection of the crowns, as a spell of very severe weather is yet possible. With regard to the young plants set out last August, an effort will be made to free the ground of weeds between the rows as soon as the soil can be had in good working order. Care will also be taken at the same time to see whether there has been any uplifting of the plants by frost, and to make firm again any found in this condition.

Melons.—With the advent of the New Year comes the time for the sowing of the first lot of seeds to furnish plants for supplying the earliest crop of Melons. After Apples are over and late Grapes are finished there remains but little in the way of fruit for dessert with the exception of forced Strawberries, and in some few cases Grapes from pot Vines. Early Melons are therefore always acceptable, and when well grown greatly appreciated, and an effort is usually put forth to produce them as early as circumstances permit. A well heated structure is very essential, as success very largely hinges on this; in fact, it is useless to attempt growing them without it. Although not required for the Melons just at present, as the raising and growing on of the plants up to a certain stage are done elsewhere, it is important that it be cleansed and got in readiness beforehand, paying particular attention to the lime-washing of all brick-work when insects and fungoid pests have in the past season been troublesome. As the earliest lot of plants succeeds better grown in large pots than on mounds of soil, these to the required number should be placed in position and then filled with suitable compost. The loam which forms the principal constituent should be sterilised in all cases where wireworm and eelworms are known from past experience to infest it, this being a sure way of eliminating these pests and averting disappointment. The only additions to the loam in our case, as the latter is of a heavy nature and full of fibre, are bone-meal and lime rubble, a 6-inch potful of the bone-meal and a 10-inch potful of the lime rubble to each barrow load sufficing. A good supply of drainage material in the bottom of the pots, 14 inches in diameter, is very necessary, the covering material

for which, to prevent finer particles from getting in and choking it, being flaky pieces of loam. Firm ramming is insisted on, the pots being filled to within an inch or so of the rims. If the bed in which the pots are stood, almost close together, has a chamber beneath containing hot-water pipes for supplying bottom-heat the grower has not then to rely on tree leaves for that purpose. All the same the bed, if filled with them, proves useful in a variety of ways up to the time that too much shade is cast by the growths on the trellis. If got in as soon as the pots are fixed in position they will have parted with sufficient of the heat engendered by them to prove harmless when planting time arrives. The seeds are best sown singly in small 60's filled with loam in a moist condition, which saves having to afford water before germination takes place. A propagating-case is the best place in which to raise the plants, and an improvised shelf over the hot-water pipes at the front of the house provides ideal quarters for them afterwards, or until the 6-inch pots into which they are shifted from the seed-pots when ready are fairly well filled with roots.

Early Tomatoes.—Seed of a suitable early variety will be sown at once to supply plants for fruiting in pots, and from which a crop will be taken as quickly as circumstances permit. Sowing will be done thinly in pans, and the resulting plants, when in the rough leaf, pricked off into 3-inch pots and stood on a shelf in the stove for a few days, or until they commence to root and recover, after which they will be accorded cooler quarters close up to the glass to ensure a dwarf habit of growth. When well rooted a shift into 6-inch pots will be given and the plants again returned to the shelf, from which, when the time arrives, they will be transferred to 10-inch pots in which they are to fruit. By the time they are ready for the final shift each plant is usually carrying one truss of fruit in the swelling-off stage.

A. W.

MIDLAND COUNTIES.

Bush fruits.—All bush fruits should now be pruned. Thin out old Gooseberries, spurring in the side shoots to two buds. Give the trees a dusting of lime and soot and repeat when necessary, as this helps to keep off the birds. Red and White Currants should have the side shoots spurred in to three buds and the leading shoots cut back to 6 inches. Black Currants only need some of the old wood removed, and if this was done soon after the fruit was cleared, as advised, they need very little, if any, further pruning. All the trees will be greatly benefited by a good dressing of rotten manure. Planting has been much delayed by the unusual rainfall, and it is necessary to push on with this work at every favourable opportunity. Newly-planted standard trees must be secured firmly to stakes to prevent damage from strong winds. The stakes should be fixed in position and well driven into the sub-soil before the trees are planted. If grafting is contemplated the scions should be collected and the stocks headed back before the sap commences to rise, allowing about 6 inches of the stem for a second cutting when grafting time arrives. Select scions of a medium size and heel them in in a shaded place until they are required.

Strawberries in pots.—When the earliest plants begin to throw up their flower-stems place them in the highest and most airy part of the house where they can have plenty of warm air; this will prevent the leaf-stalks becoming drawn and favour

the fertilisation of the flowers when they begin to open. At this season of the year Strawberry flowers need to be pollinated very carefully with a camel-hair brush. The plants are very susceptible to attacks of red-spider, and although they may have been thoroughly sprayed with an insecticide it will be necessary, after the flowers are set, to syringe the foliage twice daily with soft, tepid water, taking care to wet the under-sides of the leaves. Promote plenty of atmospheric moisture by damping the paths and bare spaces in the house frequently. As the pots are well filled with roots, applications of weak liquid manure alternated by some approved fertiliser, should be given two or three times each week. Plants for succession may be placed on a shelf near the roof glass in a Peach-house in which the trees have recently been started. Before bringing the plants under glass lay the pots on their sides, and syringe the foliage well with an insecticide. Remove a little of the surface soil from the pots and replace with fresh loam mixed with a suitable fertiliser. Late plants from which fruit is to be gathered in April and May must be fully exposed to the elements unless the weather is wet—when the lights can be tilted—or very severe, when a few Fern-fronds may be spread over the crowns in preference to covering the glass with mats.

Herbaceous borders.—Where not done during autumn, any rearranging required may now be carried out when the weather permits. If necessary dig or trench the borders, working in a quantity of leaf-soil, or plenty of good manure if the soil is impoverished, remembering that most herbaceous plants are gross feeders. When replanting, divide the old clumps, selecting the strong outside pieces for planting. Plant everything in good broad masses, with due regard to colour effect, leaving spaces between for hardy and half-hardy annuals. Allow some of the taller plants to come well forward and thus break the formal outline. On no account should planting be done in wet weather. When the replanting is finished all the plants should be accurately labelled, using labels that are likely to last in good condition for some time.

The tree Pæony (Pæony Moutan) needs the dead points of last year's shoots cut back to the first strong buds, which are now beginning to swell. The larger bushes will be examined and the weak shoots removed. If the tree Pæonies are grafted, suckers are liable to appear, and it is important to remove these directly they are observed. If herbaceous Pæonies were not mounded after the decay of their leafage last autumn this should be carried out without delay. The surface soil should be removed from about the roots and a thick dressing of decayed manure spread evenly all round them, returning the surface soil, which, if of a porous description, should be trodden firmly. This dressing will act not only as a stimulant but will enable the plants to pass through their blooming period without having to be watered. The present is not a suitable time to divide Pæonies. They should be left until after the flowering period, when they may safely be divided and replanted.

The rock garden needs much attention at this season. Many close-growing plants lose some of their shoots in the winter, and these must be removed to prevent the mischief spreading. Many plants, too, spread beyond their proper limits, and have to be entailed. In the case of dwarf-growing plants pieces may be pulled away, but with shrubby subjects the knife must be used, cutting away more of the under-lying than the over-lying shoots. It is possible to reduce the plants without making them

appear unsightly for weeks afterwards. Many plants also require a top-dressing of suitable soil.

Rhododendrons and Azaleas, owing to the natural soil in these gardens containing a quantity of lime, can only be grown in raised beds of prepared soil. Several groups are planted in this manner on the outskirts of the rock garden with good effect. These will now be given a good top-dressing of leaf-soil one part, decayed cow-manure one part, road sand one part, and good fibrous peat.

Rhubarb.—Batches of Rhubarb may be taken up at intervals and placed in gentle heat, but in addition some of the roots in the open ground should be forced in the position they now occupy, much in the same way as Seakale. This latter practice is preferable to lifting the crowns and forcing them indoors, unless crowns that have been specially grown for the purpose are obtainable. By the indoor forcing system the plants are so weakened that they need at least two years to regain their vigour. If the details of forcing in the open ground are carried out intelligently, the fermenting materials removed in good time after the forcing is over, the beds forked, and no more stalks pulled during the present season, the roots will be little the worse for slight forcing.

Parsley.—Should the stock be running short, plants may be lifted and put thickly into boxes, and if placed in heat will soon start into growth. Seeds should also be sown now and placed in a temperature of 60 degs. As soon as the plants are large enough to handle they may be pricked off into a warm pit. A supply from this sowing should also be available for planting out in April on a warm border.

F. W. GALLOP.

SCOTLAND.

Raspberry plantations.—In the course of the week some progress was made with the final training of Raspberry-canes. It is only about six years since these canes were planted. They have been well done, too, and the canes of the current year are numerous and well ripened. At the same time it is always of advantage to renew Raspberry plantations, for not only are crops heavier from fresh soil, but the individual fruits are much finer. For jam-making, medium-sized fruit is quite good, but for dessert or for bottling that of larger size is preferred in the kitchen or for still-room purposes. The canes in the break, referred to are of excellent quality and no misgivings are felt as to a plentiful supply of this always popular fruit in the course of the coming season. Unfortunately, training was put a stop to by heavy and incessant rainfalls, but, nevertheless, some progress was made. When the work is finished a light forking-up will be given and the entire quarter will be mulched with short and well-rotted manure, of which we have some quantity to spare for this purpose.

Seed lists begin to come to hand, and I think that we gardeners might do what we can to help the seedsmen at this time. They, like ourselves, are suffering from shortage of labour, and by forwarding our orders as soon as possible we will give them a better chance of coping with their spring work—always, as we know, a busy time with seedsmen, and one which will be especially so during the forthcoming spring. This is, perhaps, scarcely the place in which to refer to it, but I lately noticed that the Scottish seed trade had interviewed the Secretary of State in Edinburgh as to the "starring" of foremen in the various seed establishments. If these men are necessary, then, in an equal

degree, so are foremen gardeners; but I have not yet heard that they are asking for exemption. Skilled labour is necessary in all departments if work is to go on. Many head-gardeners are attested under the Earl of Derby's scheme, and it follows that if both these men and their foremen are called upon for service horticulture will suffer.

Novelties.—Judging by the lists to hand there is no lessening of the annual crop of novelties. It is always advisable to test a certain number of these annually, because now and then something really good is put on the market. At the same time it is a mistake to buy so-called novelties year by year to the exclusion of older varieties which have stood the test of time.

Strawberries.—Where early Strawberries are required a batch may now go into low pits nearly filled with leaves. In these the pots may be plunged—the foliage almost touching the glass—until the flower-spikes show. Then they may be removed to shelves in a warm house, pans of light, rich soil being placed beneath each pot, into which the roots will penetrate as progress is made.

The winter dressing of fruit trees has been greatly interfered with by the continual rains. Some Pear-trees which were attended to in the early part of the week will require to be again syringed, in order that things may be quite safe. The dressing is applied through a fine syringe, and care is taken that the bark close to the wall is attended to equally with that in the front of the trees.

Hydrangeas.—When these are wanted early in the year now is the time to introduce them into heat. Select those which have well-developed buds for the first batch, and let there be no scarcity of moisture during the forcing. Liquid manure is of much use to these rather gross-feeding plants, occasional doses of weak soot-water being as valuable as anything.

Plants in frames and pits were again thoroughly looked over during the week. At this time damp is the chief enemy; and, therefore, free ventilation is given on all suitable occasions. From time to time the temperature in such pits as are heated by hot-water pipes is run up rather briskly, the sashes being opened to the full extent of the tilts at the same time. This causes a brisk circulation of air, which is all to the advantage of the plants in the frames. Watering in the meantime is almost entirely dispensed with, except in the case of plants in pots which absolutely require moisture.

Firing.—At this period of the year, and with coal at its present prices, care is needful if fuel is to do its work economically. In a general way, much depends upon the fireman, some men being able to keep up the necessary heat with half the expenditure of material which another may require. Let flues and furnaces be cleaned out thoroughly at least once a week, and, as has been previously recommended, when time can be spared, give everything connected with the apparatus for heating a thorough overhaul. When fires are lighted and fairly under way the draught can be reduced. A good stoker can do much with the damper of a furnace, and it should never be out more than an inch or two when the fire is burning brightly. Bright fires are to be avoided in the early part of the day when the sun is apt to shine; but the pipes ought always to be nicely warm by 5 o'clock. Afterwards, a look round and a stir up at 8 p.m. will make things right for damping down round about 10 p.m.

Vegetable garden.—There has been little opportunity during the week to do any work upon the soil; indeed, the needful daily work of getting supplies of green vegetables has been most unpleasant, the sodden state of the soil and the dripping condition of the plants being most undesirable. At the same time supplies continue to be plentiful, and present appearances point to a prolonged season for green vegetables. Less trouble than usual is being experienced with wood-pigeons, and owing to the precaution taken in wiring in Sprouts, Savoys, and Curly Greens, pheasants are not noticeably destructive. These latter birds, it will be found, do not readily fly into an enclosed space, but they will soon find their way into unwired enclosures. Beet, Turnips, Potatoes, Salsafy, and root crops generally are regularly inspected from time to time.

Fruit-room.—Owing to the spell of inclement weather the fruit-room was thoroughly examined during the week. All spotted and doubtful fruits were removed. Mid-season Apples are not keeping well; but late varieties seem like giving a good account of themselves. These are hard, plump, and firm, and ought to prolong the season till well into the year. Excepting in very frosty weather, it is of advantage to admit plenty of air to the fruit-room.

W. MCGUFFOG.

Balmæ Gardens, Kirkcudbright.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Cobæa scandens (Mrs. Northey).—Your best plan would have been to leave your plants of *Cobæa scandens* alone until all danger of severe frost is past, and then cut them down to within 2 feet or 3 feet of the ground, when they should shoot out strongly. The only danger of cutting the plants down earlier is that if a severe frost comes after the fresh shoots have started these are killed, and the plants themselves often destroyed; whereas a frost which cuts the tops often leaves sufficient vitality in the lower part of the stems to make them break again.

A Mesembryanthemum (Bewilderd).—The specimen No. 2 is a *Mesembryanthemum*, but as there are over 300 species it is impossible in the absence of flowers to say anything further with regard to its name. *Mesembryanthemum* of this section can be readily increased from cuttings taken in the spring and inserted into well-drained pots of sandy soil and kept moderately watered, as from their succulent nature an excess of moisture would be injurious. The cuttings will not need to be put into a close propagating case, but simply stood in the closest part of the greenhouse and shaded from bright sunshine.

Asparagus plumosus from seed (C.).—Fresh seed of this will germinate freely in a good hot-bed in the spring. The best soil in which to sow it is sandy peat, which must be kept constantly but moderately moist. As soon as you can handle the seedlings, prick them out singly into small pots, using sandy peat and leaf-mould, returning them to a moderate hot-bed until they are well established and growing freely. This *Asparagus* does best in the warm, moist atmosphere of a cool stove or intermediate-house, lightly shading it from hot sun. If you have any old plants and wish to increase your stock, you can do so by division. A crown or two with a few roots attached will soon make a strong plant in a warm-house. It also does well in an unheated greenhouse during the summer.

The Belladonna Lily in pots (E. H. B.).—This may be grown in pots, but is far more satisfactory when planted out in a warm border, such as one in front of a hothouse and facing south. Under these conditions the flower-spikes, with their charming pink blooms, are pushed up, usually in September, before the leaves. After the blossoms fade the leaves are pushed up, and continue to grow during the winter. They turn yellow and die off late in the spring, the bulbs remaining quite dormant till the flower-spikes again appear. If grown in pots, the bulbs need a good loamy soil. After flowering, the plants must be kept in a frame to protect the leaves during the winter, then in spring, as the plants go to rest, they may be stood outdoors in a sunny spot, giving but little water till the flower-spikes appear. We do not reply to queries by post. See our rules to correspondents.

VEGETABLES.

Chicory (Yorkshire).—The forcing of the roots is an easy matter. When the leaves have decayed a number of roots should be taken up and laid in soil in some cold shed or other structure where they will not be frozen, and from this store they can be removed in batches for forcing as wanted. This is merely a precaution, be it understood, in case of severe frost or snow setting in and preventing them being lifted from the beds, where the main lot should be allowed to remain. The quantity of roots to be forced at a time will depend upon the demand for the salad. For a small family as many roots as can be put into a 12-inch pot will be sufficient at one time. Whether the roots are forced in a bed or in pots or boxes, they should be buried up to within an inch of their crowns in light soil of any kind, watered, and placed in a temperature of from 50 degs. to 60 degs., and be kept in the dark. If a dark shed or cellar be not available the crowns may be covered with an inverted flower-pot or box, which will do quite well. The leaves soon push out, and they should be cut when they are young and tender, and always just before they are required for salad. The roots will push out leaves a second, and even a third, time after being cut, but the growth gets weaker, and the best plan is to introduce a succession of fresh roots before the supply becomes exhausted.

MISCELLANEOUS.

The Lackey-moth (Rev. E. Hackett).—The eggs you send are those of the Lackey-moth. The best way is to look for the bracelets of eggs that surround the shoots. The way in which the eggs are laid is very peculiar, they being deposited in spiral lines round the shoot in many cases as many as twenty rows being found. When the eggs are removed they should be at once crushed, so as to make sure they are not hatched. The caterpillars appear in April and May.

A weedy lawn (S. Lamb).—The weed you send specimens of is the Bugle (*Ajuga reptans*). You cannot use a weed-killer, and lawn sand would be of no use. The best thing you can do is to dig out the weed during the winter, and in the spring to put on to the bare places some good loamy soil, sowing down in the coming April with good Grass seed. You can, if you care to, apply a top-dressing directly you have cleared out the weed, letting it remain all the winter so that the frost may break it down. Then having worked the top-dressing well into the soil you may sow the Grass seed as advised above.

Decaying leaves (M. F. Innes).—To accelerate the rotting of tree leaves it is best to put them into a heap and let them become thoroughly moist, then frequently turn them. But if needed only for ordinary manure, then it is better still to mix with them all sorts of garden refuse, having the whole turned two or three times, some soot being strewn over the heap when the turning is proceeding, to kill slugs and worms. We have seen such a heap in capital condition for use in about four months from the collecting of the leaves. When decayed leaves are needed to make leaf-mould for potting, then they should be kept alone, and need, with an occasional turning, fully a year to enable the material to be thoroughly decayed.

SHORT REPLIES.

R. N. Ferroll.—1, The best tree for your purpose would be the Japanese Arbor-Vitæ (*Thuja japonica*). The odour of the crushed shoots resembles that of Eucalyptus. 2, Holly would make the best screen. Procure strong, two-year-old seedlings, and prepare the ground

well before planting.—*Skisdon.*—The seeds of the Laburnum act so violently as an emetic that they are justly deemed poisonous, and we would advise you not to run the risk. 2, You should procure a copy of the "Vegetable Garden," in which descriptions of the various herbs are given, also their mode of culture.

NAMES OF PLANTS AND FRUITS.

Names of fruits.—K. W.—Apple: Sturmer Pippin. Pear: Glou Moreau.—R. E. B.—Apples: 1, Dutch Mignonne; 2, London or Five Crowned Pippin; 3, French Crab.—A.—Pears: 1, Judging by flavour more than from outward appearance—skin having turned a blackish brown—is, we think, Beurré Duhaume; 2, Appears to be, as far as flavour and shape are concerned, Susette de Bay.—F. G. M.—Pear Winter Nelis.

Peat ashes.—Can anyone tell me if the above may be used with advantage to plants, etc., just as wood ashes are?—R. B.

The Gardeners' Royal Benevolent Institution (founded 1838).—The seventy-sixth annual general meeting of the members and subscribers of this institution will be held at "Simpsons," 101, Strand, London, on Thursday, January 20th, 1916, at 2.45 p.m., for the purpose of receiving the report of the committee and the accounts of the institution (as audited) for the year 1915; electing officers for the year 1916; and for the election of eighteen annuitants on the funds. The chair will be taken by Sir Harry J. Veitch, F.L.S., V.M.H., Treasurer and Chairman of Committee, at two forty-five o'clock. The voting papers have been issued with the following appeal:—

The committee, in sending the accompanying voting paper, tender their grateful thanks to those who have so kindly enabled them uninterruptedly for so many years to administer the funds of the institution with so much benefit. Owing to the terrible stress and anxiety at this time, the committee find their annual income much diminished—largely in consequence of the inability to hold the usual festival dinner which has always been so helpful in adding to the funds of the institution—whilst the appeals for assistance have become more numerous than ever. In these circumstances the committee are compelled to elect eighteen candidates only from an approved list of sixty-one applicants. Even in coming to this decision they sincerely rely on a continuance of that liberal and generous support hitherto given to them in maintaining the work, and for which they now most earnestly appeal. Any gift you may feel disposed to send will, I can assure you, be greatly appreciated.—HARRY J. VEITCH, Treasurer and Chairman of Committee.

Burpee's Seeds Grow

THE truth of this famous slogan is proved by thousands of pleased and permanent customers. The Burpee Idea of Quality First,— "to give rather than to get all that is possible," combined with efficient service has built the World's Greatest Mail-Order Seed Business. **Burpee's Annual for 1916** is a bright new book of 182 pages, beautifully illustrated in colors, and a *Safe Guide to Success* in the garden. Mailed free. Write for it today,— "Lest you forget."

THE WRONG ROUTE.

THERE never was a time when there were so many ways of teaching art through academies, schools, in every parish almost, and professors and books no end, and there never was so much bad art. This is the common opinion of good judges in Paris and London. In Lord Redesdale's book there is a passage which has a bearing on this:—

"I remember how once, when a lady consulted Lord Leighton about her boy, who showed a great talent for painting, his answer was: 'Let him have the education of a gentleman in the first place; then, if he should still have an inclination for art, let him specialise.'"

There is evidence to show that the way advised by Lord Leighton is not the right way. Excellence in art is not to be had without early devotion to the work, and the education in colleges until a man is well over twenty precludes any full early training in art.

If we look at the history of our own great landscape painters we find that excellence in the result was not through any college education, but by early devotion to work, often under the poorest conditions. David Cox was the son of a blacksmith, and he was an artist with a true eye for the beautiful in nature. Constable was a miller's son, and began his studies with a painter and glazier friend in the fields—a much better place to study art than any academy. Turner was not quite so happy in his father, being the son of a barber, but even in Maiden-lane a genius may arise. Old Crome began life as a doctor's errand boy. These were among our very best painters, leaving out those who died young, like William Müller. Carolus Duran, whose portrait of Pasteur—a masterpiece—was seen in London some years ago, told me he was at work in the Academy at Lille at eight years of age.

By far the best landscape art in England arose from conditions different from those laid down by Lord Leighton, whose own work does not justify his teaching. A picture by one of the old Dutch painters who, as boys, were apprenticed to their craft, was worth all he ever did. Watts and Constable among English artists are examples of the right way of arriving at art excellence through work. Though healthy birth in country air is an advantage, it in no way frees a youth from the need of early apprenticeship.

This may seem all away from garden design and planting, but it really is not so, because the problems that confront the landscape planter are the same as those which the landscape painter has to deal with—viz., beauty, repose, breadth, and air. The man who uses trees instead of pigments has the nobler task. He has advantages, too, in that he has ready to hand the atmosphere of Corot and the sky of Diaz. The painter has much to learn in landscape, the artist planter more of the trees of the world, both in a wild state and in cultivation. Without that knowledge there can be no good design in park, field, or garden. W. R.

NOTES OF THE WEEK.

Apricot-trees.—In reply to "G. P. K.," in GARDENING ILLUSTRATED, January 8th, I have very good crops of Apricots every year by keeping the roots high up and supplied liberally with chalk, which ensures the roots not getting too dry when the fruit is setting.—C. PHELIPS, *Shillingstone, Dorset.*

Erica carnea gracilis.—This has been one of the earliest to flower this year. It has, I think, surpassed itself in beauty, the drooping habit showing well the pretty flowers. The flowers are what are called "Italian pink," a good shade, a little lighter towards the base. The tips of the flowers are dark brown. It appears to me from my experience of three years now to be slightly less hardy than some of the others. It is well in bloom now (January 14th).—S. ARNOTT.

Christmas Roses at Kirkcudbright.—Hellebores of the Christmas and Lenten Rose classes always do well in Mr. Horne's garden at Kirkcudbright, but the blooming of the large-flowered Christmas Rose, *Helleborus altifolius*, deserves special mention this year. The clumps are not protected in any way. The chief points, however, were the number and size of the flowers. At Broughton House the plants receive full attention in the shape of manure, but it is evident that the deep, black, somewhat alluvial soil suits the Christmas Rose.—S. ARNOTT.

Hamamelis arborea.—This Witch Hazel is now bedecked with its twisted yellow flowers, which are rendered all the more conspicuous by the prominent claret-coloured calyx. It is quite the best of the group, being also one of the first to bloom.

I have it among tall-growing Heaths, the dark-green foliage of which shows up the flowers of the Hamamelis. In the company of other shrubs, such as Laurustinus, Garrya, Forsythia, flowering at the same season, it is most effective. For cutting and using indoors with the Alexandrian Laurel (*Ruscus racemosus*) these branching sprays are excellent and last a long time.—E. M.

The Prostrate Rosemary.—A more charming little plant for the rock garden at this season of the year than the above could scarcely be desired. Rarely more than a few inches high, the pale lilac flowers, now opening, are succeeded by myriads of buds, the whole possessing the fragrance of the taller species. With me it has covered the ledge and fallen to the ground level of a 3 feet retaining wall, clinging to the wall as it grew. It is sometimes touched with frost, but never killed. Few plants are more easily increased, as cuttings inserted in sandy soil during late summer and autumn invariably strike. These soon make nice stuff to put out the following spring.—E. M.

Dimorphotheca aurantiaca.—I was very much struck with this last year, and pen a few lines for the benefit of readers who have not grown it. Though the plant only reaches 15 inches in height, it is covered throughout the summer with dainty blooms, which are chiefly of a brilliant orange colour. I have grown it in several ways, but the best method in my garden, exposed to all the cold winds that blow, is to sow it in pots in March in gentle heat, pricking off in late March and planting out at the end of April. Dead flowers must be removed frequently, and the plants set 9 inches to 12 inches apart each way, when they form fine little bushes.—E. T. ELLIS, *Sheffield.*

The Winter Aconite in the South-west of Scotland.—The proximity of the Solway Firth and the influence of the Gulf Stream are responsible for the early-flowering of plants in the Kirkcudbright district. After a rather uncongenial time it was an unexpected pleasure to observe a good display of the Winter Aconite in the garden at Broughton House, Kirkcudbright, on January 10th. The flowers were not isolated ones, but were in great numbers, and brightened up the garden. In my own garden, further east, and some ten miles as the crow flies from the Solway, there is not yet a single bloom of the Winter Aconite to-day (January 14th). Although a December flower in some

places, it is but seldom that it can be recorded in that month in Scotland.—S. ARNOTT, *Maxwelltown, Kirkcudbrightshire.*

Iris histrioides.—This very beautiful winter-flowering Iris does not seem to be well enough known. It is at least as easy of cultivation as its later relative, *I. reticulata*. I have grown it now for several years, and find that each bulb produces a second one regularly, and no frost seems to hurt it. I have a batch now (January 16th) in my rock garden just expanding its large pale-blue flowers.—P. WILLIAMS, *Newbury.*

Storing Apples.—I agree with "T. P.," page 27, that late Apples are all too often spoiled by trying to preserve them on lattice stages in fruit-rooms where the air is much too dry and warm. If a cool, slightly damp cellar with a brick floor is available, nothing is better than an ordinary bushel basket to store clean, firm fruit in, placing them carefully in the baskets to avoid bruising, and, of course, making sure there are no decaying portions in the skin. Occasionally examine the fruit to make sure all are keeping soundly, removing any suspicious fruits. Stored in this way, last year I kept fruit of Cox's Orange Pippin until the middle of April in good condition.—S. P.

A note from Glasnevin.—We have continual rain; nevertheless, on Saturday (January 8th) I gathered *Chimonanthus fragrans* (the Winter Sweet), *Saxifraga Burseriana major* (forty-three blooms on the cushion), *Iris Vartani*, *Iris stylosa alba*, *I. s. Elizabethæ*, *Iris histrioides*, blue Primroses, Jack-in-the-Green, Red Polyanthus, Snowdrops, Crocuses, Christmas Roses, *Coriaria nepalensis*, California Alder, *Garrya elliptica* (well out), Lenten Roses, *Jasminum nudiflorum grandiflorum*, *Lonicera Standishi*, Aconite, Pyrus, Wallflower, *Lithospermum prostratum* Heavenly Blue, Pansies, *Aubrietia* Dr. Mules, Bachelor's Buttons, *Tussilago fragrans*, and *Daphne Blagayana*, which, arranged in a Nankin China bowl well stuffed with lovely soft Co. Wicklow wall Moss, make a picture of spring that is in keeping with the song of the thrushes and the soft little trill of the robins outside.—W. P. M.

Carrya elliptica.—This is now at its best. The pendent and delicate grey-green catkins, nearly a foot in length, are abundantly produced from the leaf-axils, giving the whole shrub a most picturesque and striking appearance. For cutting, too, it is lovely, and if gathered when the catkins are half-developed these will open to their full extent in a warm room, sometimes becoming longer than those left on the plant. I have seen it growing on walls in the north, but it is when seen as a large, spreading bush that its true value is seen. The plants referred to are growing in the open, where I have known them get touched by frost during hard spells, therefore it is advisable to select a sheltered position, protected from north and east. Being rather impatient of moving after occupying one position for a few years, it should be planted where it is likely to remain. I saw a good specimen a few years ago in a garden in Hertfordshire, fully exposed, and annually draped with flowers. This to my knowledge was never injured by frost. The finest catkins are seen on plants growing in good ground, but bushes established in poor soil appear to winter best, due possibly to the wood being better ripened.—E. M.

Two winter-flowering Honeysuckles.—Among the earliest-flowering shrubs are two bush Honeysuckles, *Lonicera fragrantissima* and *L. Standishi*, which in mild

winters are usually at their best during the latter half of January. *L. fragrantissima* is in many gardens a sub-evergreen, while in other places it may be quite evergreen or deciduous. It is a native of China, and was introduced in 1845, although it is not very common. Mature bushes may be upwards of 6 feet high and as much across, the branches being long and slender. The white flowers are deliciously scented, and produced in pairs from the wood matured the previous year. The other species, *L. Standishi*, is also of Chinese origin, and was introduced with the last-named. It is, however, a common shrub, and, of the two, the hardier. By its more erect growth, stouter and shorter branchlets, longer oblong leaves, and creamy-white flowers, it is easily distinguished from the other plant. In most gardens it blossoms very freely, and its presence can be detected at a distance of several yards by the fragrance of the flowers. When growing in the open, fruits are not often matured, but when planted against a wall quantities of bright red, fleshy fruits are ripened during May or June. An occasional thinning of the older branches and a surface-dressing of manure now and then may be given with advantage. Cuttings of half-ripe shoots root readily if inserted in sandy soil in a close frame in summer.—D.

FRUIT.

ESPALIER FRUIT-TREES.

GENERALLY speaking, only Apple and Pear trees are trained in the form of espaliers. Both Plums and Cherries can also be grown as such, but they are less suited for the purpose, consequently, it is not possible to obtain such well-trained examples in their case as with Apples and Pears. The value of espaliers is well known, as not only do they occupy less space than pyramids or bushes, but the trees cast but little shade on whatever may be grown in their vicinity. They are also very productive, and, as to the quality of the produce, this is equal in every respect to that found in fruit yielded by the previously-named forms of tree. If planted so that the trees are distant some 3 feet to 4 feet from the edge of the walks in the kitchen garden, narrow borders which can be turned to account for a variety of purposes are then obtained.

PRUNING.—The pruning of espaliers differs but little from that accorded wall-trained Apple and Pear trees. When established, the various tiers of branches of which each tree consists are clothed from end to end with fruiting-spurs. The young wood produced in the latter is, and always should be, stopped twice during the growing season, *i.e.*, early in July and again the latter end of August. The result of this treatment is that all that requires to be done now is to shorten all these stopped growths back to four buds. With some varieties a thinning out of the fruit-buds in the spurs becomes an absolute necessity when the trees attain age, otherwise they become so congested that the fruit produced is small and of second-rate quality. Other varieties, again, are prone to set a great number of fruit-buds, and make little or no new growth, a case in point being *Emile d'Heyst* Pear. To counteract this tendency the spurs must not only be kept well thinned, but so regulated that they stand a good distance apart on the branches. By curbing their fertility in this way a greater quantity of young growth results.

SPUR-PRUNING may also be applied to old yet healthy trees with beneficial re-

sults. Every other branch may be denuded of spurs in one season, and the remainder similarly treated not in the next, but the year after. The branches in the course of a few seasons will then become by this process entirely reclothed with a new set of spurs, as new growths will result at intervals throughout their entire length. Another method is to dispense with every other spur on each branch now, and the remainder in two years' time. If the bases of the old spurs are left about an inch in length several young growths will be emitted by the latter the following season. These, when stopped, form the bases of new or future fruiting spurs. All this can be carried out at the present time. To prevent the spores of "canker" or other fungoid diseases entering the wounds smear the latter over with knotting.

G. P. K.

NOTES AND REPLIES.

Apricots.—Your note about Apricots is excellent. I fancy that the old trees are dying off because they are old, and that the nurserymen now bud or graft upon a wrong stock. You could have added at the end of your note a word to the effect that what the Royal Horticultural Society is attempting to do at Wisley is already being admirably done at several establishments in different parts of the country—Rothamsted, etc. I was always under the impression that when Sir Thomas Hanbury offered Wisley to the Royal Horticultural Society he made the condition that he should be allowed to appoint three trustees in order to safeguard the garden against its being put to uses other than those he intended. He spoke about it amongst his friends and gave his reasons for not giving it unconditionally to the Society. There are many who think that the trustees have lamentably failed in their duty, but I do not go so far, for there may be many considerations of which outsiders know nothing. What they do know is that the garden was given for horticulture and all questions appertaining thereto, and of interest to the general public; the Apricot question for instance. They have spoiled the garden with their buildings, ruined its charm, and the horticulture is indifferent. Enormous sums are being spent in equipping the laboratories and diverting the purpose of the garden from horticulture to second-rate science.—F. L.

Fruit-trees under glass, now in position, have been sponged over. There is never much danger at this time of insect pests, but prevention is better than cure, and a strong soapy wash keeps things right. Top-dressing has been attended to; in the case of stone fruit some lime was added. For some time care in watering will be needed. Fruit-trees in pots are apt to be deceiving, and any shortage of moisture may quite easily result in bud-dropping. Figs in pots call for special attention. If these are not to be hurried on any dampness in the atmosphere may tend to the rotting of the terminal buds—a state of matters which is fatal to success. Free ventilation on all suitable occasions is recommended.—W. McG.

Extending fruit trees.—When a Peach, Apricot, or Plum on a good aspect on a wall or building has filled its allotted space, and appears capable of doing more and better work by extension, it will pay to give it more room if possible. Take the Grape Vine. If we plant a dozen or more Vines in a house a certain number will take the lead in a general way, and if those were allowed to extend they would bear finer bunches and berries. Instances could be given where this has been done with good results. I have seen the same

thing happen with Figs and other fruit trees on walls, and also in orchards, where the trees have been allowed more room. The same thing happens in the case of vegetables and flowers, Sweet Peas for instance. Now that cultivators give more room to their Sweet Peas longer spikes and finer blooms are obtained. To carry this extension out to the best advantage we must begin right with the base, and the foundation of all cultural improvement lies in the deepening and improving of the soil, and if we want all-round improvement we must fit the soil to the crop.—E. H.

Dessert Plums under glass.—Most of the Gages may be grown for dessert under glass quietly forced merely by keeping out frost after the buds start into growth. The following I have had good both in pots and also planted out and trained near the glass thinly,

TREES AND SHRUBS.

VITIS HENRYI.

This is one of the recently-introduced plants from China. When properly planted it grows rapidly and then forms an interesting covering to a high wall. In the south of Ireland it is found to dislike the sun, preferring a shady position facing north, and a good, light, somewhat damp soil. Its leaves are dark green bordered with silver, and on the reverse side of a deep red-purple, which is chiefly noticeable when the foliage is caught by the rays of the evening sun.

R. H. B.

The Heavenly Bamboo (*Nandina domestica*).—Although introduced to this country

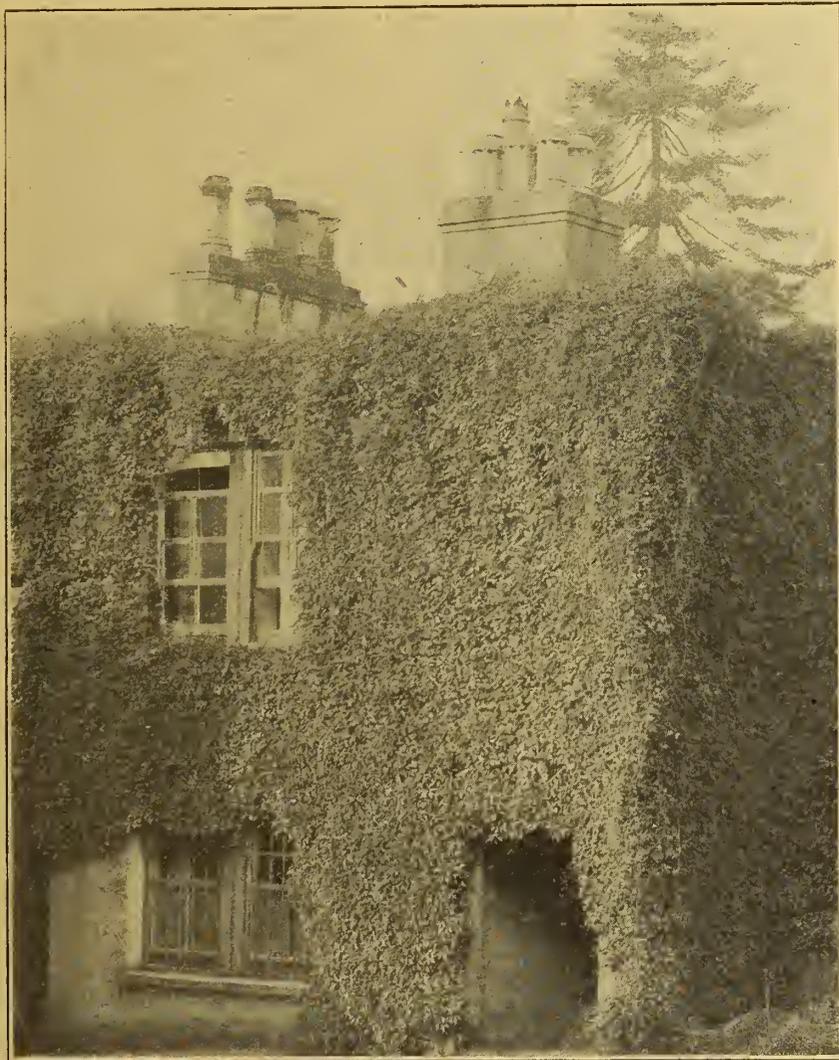

every garden however small. In that country it bears sprays of red fruits, but with me it carries annually stiff, erect, white panicles of bloom, but never fruits, the flowers apparently coming too late in the season. It fruits freely in France. I have grown it on hot, sunny walls in Surrey, but in this way it was not seen at its best and never produced fruit. The most effective way of growing it is to plant a small group, when its elegant Bamboo-like appearance is easily recognised. The leading growth, on becoming bare of leaves at the base, is furnished with young growths which break out around it, the whole having a pleasing effect and reaching eventually several feet in height. Half-developed leaves are very pretty when cut, their shining surface and charming tints showing to great advantage under artificial light.—E. M.

The Willow-leaved Magnolia (*Magnolia salicifolia*).—Although introduced as recently as 1906, this species has already blossomed well in the British Isles, and has proved worthy of inclusion amongst the most attractive kinds in the family. It is a summer-leaving species, and in its native country, Japan, grows 20 feet to 30 feet high. From its behaviour here it will doubtless attain similar dimensions. The rather slender branches are clothed with narrow, Willow-like leaves, the larger ones each about 4 inches long and nearly 1½ inches wide. Towards the end of April glistening white flowers are borne in advance of the young leaves, the individual blossoms being 3 inches to 4 inches across with long, narrow petals. Planted in a position sheltered from cold east and north winds, it grows rapidly, adding to its height by 12 inches or more each year. When plants can be secured on their own roots it is always advisable to select them in preference to those that have been grafted. As yet, however, it is a rare plant and does not appear to be obtainable in quantity.—D.

The Chinese Arbor-vitæ (*Thuja orientalis*).—When planted under favourable conditions this forms a handsome specimen. Although in the British Isles it assumes the proportions of a large bush, it attains the dimensions of a tree up to 34 feet high in China. Introduced over 150 years ago, it has long been popular for gardens, either under the name that heads this note or the synonym of *Biota orientalis*. It is easily distinguished from other *Thujas* by the branchlets standing out at right angles to the main branches, and by the woody scales of the cones. A great deal of difference is noticeable in the behaviour of individual plants, for whereas some may be free growing and of rather open habit, others are of dense habit, very wide in proportion to their height, and increase slowly in height, never becoming very tall. It is a mistake to plant this species in gardens in towns where smoke or chemical fumes are prevalent, whilst it should also be left out of tiny gardens, such as are often attached to small villa residences, for it is only when allowed plenty of space that it is seen to advantage.—D.

Chinese Chestnut (*Xanthoceras sorbifolia*).—The note by "E. M." (page 16) is interesting to those of us who have tried it without any real success. My little experience of it and the information I have received concerning it corroborate the statement in "The English Flower Garden" to the effect that it requires a warmer climate than that of Great Britain.—S. ARNOTT.

The Fastigate Tulip-tree.—The erect-branched Tulip-tree (*Liriodendron tulipiferum fastigiatum*) is especially useful for small gardens, where the ordinary Tulip-tree would take up too much room. It is quite erect in growth, and the branches assume an almost vertical position, so that a fair-sized tree in point of height takes up very little space.—S. A.

Vitis Henryi at Ashbourne, Glounthaune, Co. Cork.

after the manner of Peaches, the pruning to be a mixture of spurs and young wood, leaving a healthy young shoot where there is space. Of course, the crop must be thinned if too heavy. Early Transparent Gage, Oullin's Golden Gage, Purple Gage, and Belgian Purple bear freely; Coe's Golden Drop is indispensable, and Coe's Emperor is also good. Plums bear freely when grown in pots. When forming a collection, it is best to select the trees and pot them in the autumn. We need not wait for every leaf to fall, but after potting firmly let the trees stand outside on a foundation of ashes till the new year, sheltering the pots and roots with litter if frost comes whilst outside. As soon as taken inside dress with a suitable insecticide, so that they may start clean.—E. H.

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. Cloth, medium 8vo, 15s.; post free, 15s. 6d. Of all Booksellers or from the office of GARDENING ILLUSTRATED, 63, Lincoln's Inn Fields, London, W.C.

as far back as 1804, it is only of late years that it has been planted to any extent in the open air, this being partly due to doubts as to its hardiness. It has passed unharmed through 20 degs. of frost both in its native land (China) and in this country, and therefore is far from being tender. It belongs to the Barberry family and should be given similar treatment, except that a little shelter from strong winds is also an advantage. It is evergreen, its leaves, each 18 inches long, being finely cut, almost like those of the delicate *Aralias*. When young, the leaves are coppery red, the leaf-axils and midrib especially so, becoming deep green at maturity. In Japan, whence it was first introduced, it appears to be held in high esteem, and is to be found in almost

PLANTS AND FLOWERS.

INDOOR PLANTS.

BEGONIA FUCHSIOIDES.

W. McGuffog praises *Begonia fuchsioides* so highly that I can hardly believe it to be the plant described under that name in "Nicholson's Dictionary of Gardening." The species is usually ungainly in a small state, the plant only becoming symmetrical as it attains age and has formed a number of tall suckers. Under good cultivation these may be about 5 feet in length, and when well developed bear a fair quantity of branched panicles of brilliant scarlet flowers. I have never seen it succeed better than when planted out and trained to a pillar in an intermediate-house. There is, however, what appears to be a pink variety sold under the same name, and this deserves all that was written on page 15. It soon forms dainty little plants of good habit, every small branchlet bearing a panicle of delicate pink flowers, borne over a long season. It makes a pleasing contrast when associated with *Eranthemum pulchellum*, a charming blue-flowered plant which is easily grown under the same conditions. Both can be propagated from cuttings in early summer. A temperature of 55 degs. Fahr. is sufficient during winter. Unfortunately, the *Begonia* soon drops its flowers when used in rooms. J. COMBER.

[The *Begonia* referred to by J. Comber as being somewhat ungainly in a small state, and thriving better planted out than when confined to pots, is undoubtedly the true *Begonia fuchsioides*. At the *Begonia* conference held at Chiswick in 1893 Mr. Watson, of Kew, read a paper on the best fifty species of *Begonia*. He thus alludes to *Begonia fuchsioides*:—

"Introduced from New Granada to Kew in 1847 by the collector Purdie, who found it on the Ocana Mountains. It has a woody root-stock, succulent, tall stems a yard or more high, clothed with numerous ovate green leaves, each 1½ inches long, tinged with red when young. The flowers are borne on drooping, branched panicles; colour of the whole inflorescence a rich scarlet. This is a first-rate greenhouse plant. It should be planted out and its stems trained up a pillar or tall stake."

Concerning the pink-flowered form Mr. Watson says: "A variety called *miniata* differs only in having flesh-coloured flowers." In the "Dictionary of Gardening" a different plant is evidently referred to, as the variety *miniata* is described as having smaller leaves than in the type, and with cinnabar-red flowers. Owing to Mr. Watson's experience and the fact that his paper was written some years after the publication of the "Dictionary of Gardening," we must assume that the name of *miniata* as applied to the pink form is correct.

There are some garden hybrids claiming parentage from *B. fuchsioides*. The most generally grown is *Corbeille de Feu*, the result of a cross between this just named species and the persistent-flowering *B. semperflorens*. *Corbeille de Feu* blooms throughout the greater part of the year and is extremely useful for greenhouse decoration, while it is also largely used in the flower garden during the summer.]

Early Primulas.—*Primulas* bloom in a far more satisfactory manner when a house is devoted to them than when placed amongst a miscellaneous lot of plants in a

show-house or conservatory, as the temperature usually maintained in such structures is a little too cool for their requirements. The objection to having a house filled entirely with *Primulas* can be met with the plea that there is such a great diversity of colours among the flowers when the trusses are fully expanded that they produce quite a show in themselves, especially if the *stellata* types are judiciously made use of, both to lend variety and prevent monotony in the general effect. Air is, whenever possible, admitted at the apex, and by the ground ventilators also, to avert the possibility of the atmosphere becoming over-charged with moisture, while a little artificial heat maintains the temperature at the necessary degree. Rain-water alone is used for watering, a little of Clay's fertiliser being dissolved in it to supply the required amount of plant food.—G. P. K.

Forcing White Lilac.—Aalsmeer is a small town in North Holland, about half-an-hour by rail from Amsterdam. It is a quaint little town, of the kind that the old Dutch artists loved to depict. Its roads and streets are paved with cobblestones, and bordered with trees. Canals traverse the town, and barges laden with flowers for the market pass sedately and silently along the canals. It is quite a restful picture that meets the eye in Aalsmeer. One is reminded of Dutch William and the formal gardens which became fashionable in England through his influence. Facing the station you can see a whole garden full of the artificially-trained Box and Yew trees which in England we associate especially with the Dutch tradition in horticulture. There are peacocks, and dogs and birds on pedestals—even a Teddy bear and a baby in a bath. There are about 400 nurserymen and florists in Aalsmeer, most of them engaged in the trade in cut flowers. When you come to the Uiterweg, as one of the canals of the town is called, you are told that nurserymen's houses line the banks on either side, and that you can walk for half-an-hour without coming to the end of them. Behind are the hot-houses in which they force their market produce. The plants are not placed in earth or in pots, but stand in rows with the earth they need for nourishment in a solid clod around their roots. This earth is the secret of the success of the growers of Aalsmeer. It is a black friable mould, which I was assured needs no artificial reinforcement. In October the houses are heated to 110 degs. Fahr.; but in the present month the temperature is about 65 degs. to 70 degs. Fahr., and this will be maintained until May, when the forcing comes to an end. When the blooms have reached perfection they are sorted for market according to quality.—*The Times*.

Jacobinia chrysocephala.—This forms an upright sparsely-branching plant, the orange-yellow flowers being borne in erect terminal heads. The individual blooms are of a curved, tubular shape, and disposed in a regular crown-like manner. This *Jacobinia*, during the growing season, needs a temperature above that of an ordinary greenhouse—indeed, an intermediate house is more to its liking. Towards the end of summer it may, however, be transferred to the greenhouse, and exposed to the sun and air. In this way the production of blossoms is ensured. Cuttings root readily in the spring, and these young plants may be allowed to carry two or three shoots, as if they are stopped in order to produce more it will be at the expense of blossoms. Good flowering plants may be grown in pots 5 inches to 6 inches in diameter.—K. R. W.

The Maiden's Wreath (*Francoa ramosa*).—I frequently come across plants of the Maiden's Wreath in cottage windows along with Scarborough Lilies, scented-leaved Pelargoniums, and other subjects beloved of country folk. During the last summer I saw a somewhat novel combination in a private garden made up of the scarlet Gem Mrs. Bradshaw, *Heliotropes*, the centre of the bed planted with *Francoas*, the long, flowering shoots wreathed in blossoms.—W. F. D.

FERNS.

HARDY FERNERIES.

While flowers are indispensable for the ornamentation of a villa residence, a collection of hardy Ferns forms an equally important addition, and when properly and tastefully arranged they may be made to assume as natural an appearance as they do in a wild state; the rustic appearance, too, of a hardy fernery forms an agreeable contrast to the more dressy portions of the grounds.

It is difficult to lay down definite rules for the construction of a fernery, so much depending upon the position which it is to occupy and the space at command. In fixing on the site, the first thing to be aimed at should be a shady, secluded nook—not one that can be seen from the windows of the mansion or cottage, nor yet from the flower garden, but a part that is unexpectedly come upon when walking through the grounds. The situation should also be one that is sheltered from winds. Moisture, too, is essential to the well-being of hardy Ferns, but this cannot always be given in sufficient quantity to carry them safely through hot summers. In forming a fernery, anything like straight lines must be avoided. If the space to be occupied be long rather than broad, it should be broken up here and there so as to form miniature dells, recesses, and projections; but all should have as natural an appearance as possible. The plants in all cases should be allowed sufficient space in which to develop. Where outdoor Ferns have failed to do well, the ferneries have generally been cramped for room. What is wanted is breadth and length. If the fernery be so arranged that it could be traversed by a narrow path from which the plants could be examined, all the better. The stones employed should be placed in as natural a manner as possible, and yet they should possess a certain amount of artistic arrangement.

Soil.—Anyone who has searched for Ferns in their native haunts cannot have failed to observe that they luxuriate in a light, sandy soil, and this must form, if possible, the main bulk of the fernery. I have, however, frequently used Cocoanut-fibre mixed with turfy loam, and it has always appeared to answer admirably. For very delicate sorts a compost may be formed of peat, leaf-mould, and loam, with a sprinkling of sand to keep all open and porous, but the stronger sorts will succeed best in loam without the addition of peat. When I use Cocoanut-fibre I find that it retains a considerable amount of moisture without becoming sodden. Fern roots, being generally of a wiry nature, will grow in almost any soil that is of ordinary texture, but it ought not to be too heavy. Ferns dislike manure, both in solid and liquid form. In arranging the plants I would not separate the evergreen from the deciduous kinds, but so dispose of them that when the foliage of the latter dies down in the beginning of winter, there would still remain plants enough to interest the cultivator. I would, therefore, plant plenty of sorts that would retain their verdure throughout the winter, such as the *Blechnums*, *Scolopendriums*, *Polystichums*, and *Polypodiums*. In planting, an error of too common occurrence must be avoided—viz., that of planting too deeply. Generally speaking, the crowns must be kept well above the soil, but the plants should be made firm, and the stronger-growing sorts should be planted first. Dwarf-growing varieties with fine fronds should have the most sheltered nooks assigned to them. If water exist in the fernery, a place must be found for the Royal Fern. A. G.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

A BOG GARDEN.

THE illustration depicts a corner of a bog garden, which, four years ago, was a stagnant swamp overgrown with rushes, and shows what can be done in converting such situations into beauty spots, where many plants thrive with such luxuriance that in a few months the whole aspect is changed, often at quite a modest outlay. In this particular instance the bog was caused by a stream becoming silted up, until it was lost in a swamp. In the first place an irregular channel was formed to confine the passage of the water, and to drain the surrounding ground, which was afterwards dug over and cleared of rushes and other weeds. Irregular groups of Japanese Irises, which have been a great success,

tions last season, one leaf measuring 8 feet 6 inches in diameter, and several others more than 7 feet. Details which have done much to assist this fine specimen are the heavy annual mulching of rotten cow-manure and precautions taken in the spring to prevent the young leaves being injured by late frosts.

The boulders of rock were introduced two years ago. One forms a bridge over the stream. Just beyond the left-hand end of this is a group of *Petasites japonica*. In selecting a site for this plant, one has to take into consideration its habit, as, although its large leaves are very attractive, as are also its peculiar flowers which come so early in the year—before any signs of foliage are present—it is a veritable weed, spreading with remarkable rapidity. It is useful for obscuring an unsightly spot, and will thrive almost anywhere.

T. B. FIELD.

Wych Cross Place, Forest Row, Sussex.

and the plant continues sending up new buds at intervals all through the winter, from October till March and April, except in hard frost. *Cyclamen Atkinsi*, *C. Coum*, and *C. ibericum* were all in bud, giving promise of their fascinating little flowers in red or white before long. These are lovely even when not in flower; indeed, one great charm of a rock garden is that so many of its tenants are almost as beautiful in their winter garb as when covered with blossom. A patch of *Eriogonum umbellatum*, with its neat, reddish-bronzy foliage, was very pretty, and so was a large tuft of *Sedum glaucum* showing up quite blue in a retaining wall. The silver *Saxifragas* were beautiful, some of the larger species—*Hostii*, *Cotyledon pyramidalis*, and *longifolia hybrida*—having the tips of their leaves flushed with red, giving a very pleasing effect.

The mossy Rockfoils, too, are always beautiful, *S. Wallacei* being, in my opinion, the prettiest in the colour and general effect of its foliage. Unfortunately the sparrows raid the clumps occasionally and make sad havoc, whether in a hunt for slugs or in mere wantonness I do not know. Anyhow, one becomes in time resigned to these things. There is, however, one thing I cannot bear with equanimity, and that is when a worm makes his hole in the middle of a clump of *Dianthus neglectus*, and half covers it with "casts." You cannot dig it up, but you can visit the place some mild damp night, when it lies out, and with a gentle but steady pull draw him from his hole and fling him far afield.

There is much good work to be done in winter at night with the aid of a lantern, for not only are worms about, but a good bag may be made of slugs of all kinds. There are also many hibernating caterpillars which are only too ready to wake out of their winter's sleep on any mild night and come forth to devour any young shoots they can find. Nothing seems to come amiss to them. They will eat out the centre of the silver *Saxifragas*, which are immune from slugs, or even gnaw away their roots so that they wilt and die.

I was surprised to see how early some of the wild plants which I have in my rock garden show above ground. *Orchis mascula* was throwing up its pretty spotted leaves quite vigorously, while *Orchis Morio* has been above ground for some weeks. I also have *Orchis maculata*, but that does not seem to start quite so early. *Allium triquetrum* has been up for a long time, and so has the pretty little Meadow Saxifrage (*S. granulata*), brought with the various *Orchids* from damp meadows in Suffolk, where all were growing in great profusion.

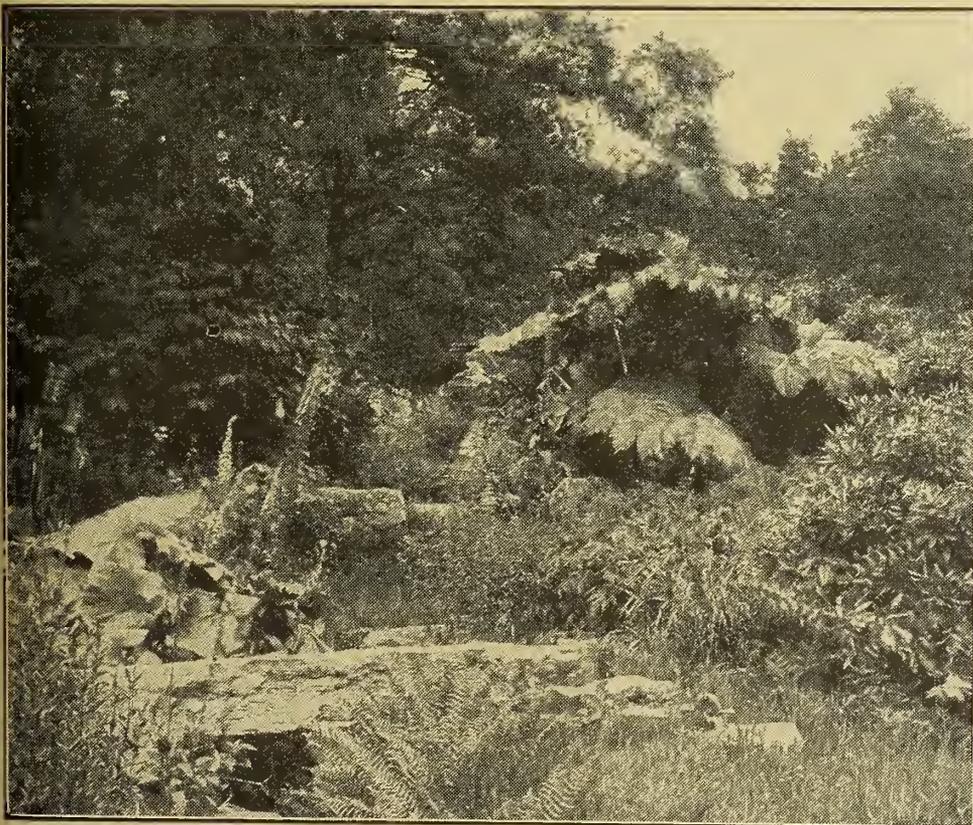

The heavy rains of December have been bad for some things. *Onosma tauricum* in particular was looking very miserable, though planted in an almost perpendicular wall. However, almost all of them came through all right last winter, which was as wet, or wetter, than this, so I hope they will survive this one. It always seems to me wonderful that plants which are used to a pure air, clear skies, and cold, dry winter should do so well in our climate, more especially when the vagaries of the climate are supplemented by the smoke and the fog which they get in a London garden. N. L.

Alyssum alpestre.—This is a dainty little species, which, with its tiny, silvery leaves, forms a close cushion of foliage, which looks neat and pretty at all times of the year. It seems quite as easy to grow as its coarser relatives *A. argenteum* and *A. saxatile*, appreciating a dry, sunny position in light soil. When in blossom the tiny, pale-yellow flowers cover the plant. It is easily increased by division.—N. L.

MID-WINTER IN THE ROCK GARDEN.

A STROLL round my London rock garden on New Year's Day was full of interest, although there was little to be seen in the way of blossom. The spell of mild weather in December, however, had brought on some of the early-flowering things, some of them being so forward that the inevitable frosts and cold winds of January are sure to spoil some of the more precocious flower-spikes. *Saxifraga apiculata* was crowded with buds, some of them almost ready to open (one odd spike did flower in November), and *Saxifraga L. G. Godseff* was equally full, but fortunately not so advanced. *Anemone blanda* and *A. apennina* were unfolding their early leaves, and so was *A. sylvestris*. *A. Pulsatilla* still seemed to be keeping dormant. *Iris stylosa* was blooming freely. There is a charm about this beautiful species of which one never tires,

were then planted, *Spiræas* in variety, notably *palmata rosea*, *Lysimachia punctata*, *Lythrum Salicaria*, *Saxifraga petata*, *Primula japonica*, *P. sikkimensis*, *Polygonatum multiflorum*, Foxgloves, *Senecios* in variety, and *Petasites japonica gigantea* were then planted. Some of these may be seen in the illustration. The intervening ground was sown with Grass seed, which is mown at intervals, and makes access easy to all parts. By adding pebbles to the channel and forming shallow pools with fair-sized stones jutting out irregularly from the sides, it now resembles a natural stream, with Ferns, *Myosotis palustris*, and *Mimulus luteus* growing along the sides of it, the two latter forming a pleasing combination. On the bank in the background of the illustration is a fine specimen of *Gunnera manicata*, and in the left-hand corner a group of *Polygonum sachalinense*, both of which were planted four years ago. The *Gunnera* assumed gigantic propor-

Lower part of bog garden, Wych Cross Place, Forest Row, Sussex.

ROSES.

BUDDING A WEeping DOROTHY PERKINS ROSE.

I HAVE in my garden a very strong-growing standard (weeping) of Dorothy Perkins Rose, on Brier stem, 3 feet high. During last season it threw up through the bush a growth from the Brier (starting about a foot from the ground) about 8 feet long, and I am writing to ask if Dorothy Perkins can be successfully grafted on to this new growth, and how and when it should be done? If so, I can see a chance of this tree being made an exceedingly beautiful one. Thanking you in anticipation of the information through the columns of your most excellent paper and for the help I get from it.—HORACE THOMAS.

[As it is not possible to graft roses out-of-doors it would be best for you to bud the growth in question, and this work is best done about the end of June or early July. The shoot being quite young it would, no doubt, be possible to insert three or four buds into the sides of the shoot itself; or the shoot may be cut down to a desirable height now, which will cause it to throw out lateral growths at the top, in three or four of the strongest of which buds may be inserted. The buds, or eyes, are obtained from any young shoots of the present season's growth that are sufficiently ripened. As a general rule a shoot may be considered in a fit state, either for giving buds or for budding upon, when the spines spring off on being slightly pushed. The shoots from which the buds are to be obtained are cut and the foliage removed, leaving about $\frac{1}{4}$ inch of the leaf-stalk to facilitate the handling of the bud. The only tool necessary is a very keen-edged knife. In cutting out the eye hold the stick of buds in the left hand, with the leaf-stalks pointing upwards. Commence the cut about 1 inch above the eye, finishing about $\frac{1}{2}$ inch below, and as thin as possible. The thin portion of the hard wood of the shoot is then removed and the eye is ready for insertion. Next make a T-cut in the shoot to be budded, being careful to cut the bark only, without running the knife into the solid wood. The bark is then forced open with the end of the budding-knife or with a sharp piece of bone or wood, and the bud is inserted, cutting off any portion of the bark that may protrude beyond the cross cut. Now bind the bud in with raffia or wool, leaving the little eye itself uncovered. The tying material is removed about six weeks later and the bud exposed to the weather. In the following February the shoot, or shoots, budded are cut back to within a few inches of the bud, which is thus forced into growth and quickly develops. You might obtain a very lovely and unusual specimen by inserting buds of three or more varieties of Ramblers, choosing related varieties, so that they would blossom simultaneously. A pretty combination of colour would be obtained by using buds of, say, Lady Gay or Dorothy Perkins (pink), Mrs. L. Dewhurst or White Dorothy (white), Lady Godiva (delicate salmon-blush), and Excelsa or Troubadour (crimson).]

Roses Frau Karl Druschki and Juliet for a hedge.—Are Frau Karl Druschki and Juliet suitable for combining and making into a Rose hedge?—D. N. P.

[The two varieties would be very suitable for hedges. Both Juliet and Frau Karl Druschki have a semi-climbing habit, and would soon grow into a nice hedge, for both varieties are of bushy growth. Give them a good start by trenching the site, and provide a store of nourishment for the future by incorporating plenty of old manure in the lower spit. After planting the hedge we would advise you to cut the plants down to within 6 inches of the

ground level in March. By doing this you will obtain a good foundation of fresh young growths, and by the end of the year the hedge will be quite as high as if you left the shoots full length.]

GARDEN FOOD.

WINTER SALAD.

WHEN the good Lettuces of several kinds disappear from the home garden some people give up salads altogether. They need not do so. In the French market gardens the growth of salads is continuous, and no doubt it might be so here, but we have to deal with things as they are. In gardens some of the things are generally very good; well-grown, which is an aid in all ways, cooked or uncooked, such as Celery. For salad it is best to use the crisp kinds, with a view more to flavour and texture than size. Apart from its uses as a salad it is very good as a cooked salad with other materials, such as Rice and Beetroot.

Corn salad is much more used in France than with us, and it deserves to be more commonly grown. With shreds of Celery it makes a welcome salad, with a little oil and squeeze of Lemon if anyone desires acid, but no vinegar. Corn Salad should be more freely grown and in a more cleanly way than it is, that is to say, in little raised borders, where it will not get too much splashed with soil. Good Cabbage cut into hair-like slices, as in America, is a help to salad-making, and it is one of the ways in which the Red Cabbage might be used.

The most common winter salad in English gardens is Endive and the forms of it, but, as usually served, it is very tough and indigestible. The French make a better use of them.

In writing about salads it is usual to enumerate a lot of varied plants, some wild and some garden, all mixed together. It may be done, but it is the wrong way, and any good French cook will say that a salad is best made of one or two things at most. Mustard and Cress are generally best left for those who like them, and also Radishes, which, however well grown, are apt to give stomach-ache. Potato salads, so much favoured by some Continental peoples, are better avoided, as one gets so much of the Potato in other ways; moreover, we doubt if the Potato contains the salts of potash that the fresh green salads do. Watercress should not be neglected. I grow a large form from seed, and it is very good. The French way of serving a garnishing of Watercress with bits of broiled meat is a tasty way of using Cress.

The hardy and useful Cress might be used also with Beetroot and Celery. It is better worth growing than Mustard and Cress, and my streamlets where it grows being now in flood, I hope for winter supply to grow it in moist beds. Apples of the pleasant acid kind are very good additions to some salads and aid the flavour—the main thing in a salad. In the country garden we have the gain of Cress away from any source of pollution. It should never touch manure. W.

NOTES AND REPLIES.

Pear Duc de Nemour.—I am interested in the note by "E. B. S., Hardwick" re Pears. I think I have a Duc de Nemour Pear-tree in front of my house in a dry situation in light soil. The tree is about sixty years old, standard, 40 feet or more high on free stock, single-grafted, roots under turf, and very little added food available. It is a great cropper, and in favourable seasons fair in size and good in quality, but, owing to age and situa-

tion, liable to spot and decay in unfavourable (dry) weather. I sent grafts to Messrs. Pearson and Sons, Chilwell, three years ago, and put my old favourite on a west wall and in bush form both on dwarfing stock to try what Duc de Nemour would do. Results are very good. I have just finished eating two Pears probably about 10 oz. each, quite perfect in form and flavour. Duc de Nemour is a grand variety under the close pruning system, and the way it will develop the twig carrying fruit is a guarantee in itself of quality in the Pears when ready. This Pear is in season a long time, often from mid-November to Christmas.—R. SUTTON, Kirk Lane.

Lamb's Lettuce.—In the issue of January 1st (p. 6) "W." notes the value of Lamb's Lettuce as a winter salad, and having grown it for many years I quite agree with what he says. It is a great favourite on the Continent, where there are some excellent varieties. In this country only one or two sorts are catalogued, mostly the Italian, but the Messrs. Vilmorin, Paris, have some superior stocks, a very fine one being the dark-green Louviers. This has a large leaf of a shining dark-green colour, and the plants form a good bunch of close-leaved, or what may be termed rosette heads. This, sown in the autumn, gives a most useful supply. Grosse graine is also a splendid salad plant, having a strong growth and large leaves. Both the above are much superior to the Italian, of which there are two forms, one much better than the other. I have, to get a full winter and early spring supply of this salad, sown in a cold frame, and got a full crop for a considerable time. Grown thus in a severe winter the Corn Salad is most useful. It is quite hardy, but well repays a little protection in severe weather.—W. F.

Pecans from America.—Thanks to the kind aid of Mr. Elliott, of the Pittsburg Nursery, my beloved Pecans have come from Mississippi, where they do so well. I was disappointed earlier in the autumn with some old Nuts that were sold in London as genuine Pecans. The Pecan is the best Nut I know, the only other Nut that comes near it being the Sapucaia, which is not always at its best when sold, probably due to having been gathered at any time by the natives.—W.

The Pear-shaped Girasole (Jerusalem Artichoke).—Of late years I have grown the large white Girasole, but should be glad if you will let me try the Pear-shaped. Girasole is a good name, but, however good a name, one never knows how it can be made to "take." Language seems to grow by ways of its own—apparently quite arbitrary and illogical. It "won't be druv," as our old people say.—G.

Keeping Apples.—I have been experimenting for the last fourteen years as to the best method of storing Apples, and find the following the most satisfactory.—I store them in a brick cold-frame, using only carefully-handled fruit, piling the different varieties in heaps, and letting them have plenty of ventilation, excepting in frosty weather. They keep sound and plump as long as the different varieties are expected to keep. I finished Lord Suffield about the middle of November, and they were then as sound and plump as when taken from the tree. I am now using Pott's Seedling, Bramley's Seedling, and Scotch Bridget. I can keep the fruit in this way well on into the next year.—H. S.

A white alpine Strawberry.—There is a delightful little white alpine Strawberry which loves a sheltered nook in the rock garden. Its flowers and fruit are somewhat larger than those of the English wild Strawberry. It is dainty in appearance, and the flavour is excellent. Given a sunny spot, well sheltered from the north and east, it will continue fruiting until late autumn. Owing to their colour, the berries are not touched by birds, even when the neighbouring red ones are stripped half ripe. It was introduced into my garden by a French friend, and it has proved a charming acquisition.—A. B. B., Ventnor, Isle of Wight.

OUTDOOR PLANTS.

SHEFFIELD PARK.

To me the advantages of our country in ornamental water are very great, and the adornment of those waters is of first importance. Other countries are not all blessed with the like noble estuaries, numerous rivers, and picturesque lakes, many of them still without much tree beauty, as in the west of Ireland. The best place I have ever seen, so far as regards making artistic use of water, is Sheffield Park. Not only is the tree-beauty very great, but there are many shrubs of interest there, the ground plants and Heaths of our

put on $\frac{1}{2}$ -inch in thickness. Apply to a good seedhouse, stating the size of the lawn, nature of soil, position, etc. On receipt of order a renovation seed mixture will be sent, arranged in suitable quantities of Grasses and Clovers, which, if sown thickly, will soon make a good lawn.

HARDY FLOWER NOTES.

ASPHODELS.—The yellow Asphodel, *A. luteus*, cannot be classed with the choicer and more showy garden plants, but it blooms early, is cheerful looking, and has great powers of endurance. Long periods of dry weather do not destroy it. The foliage may die off and the crowns may have a lifeless appearance, but rains revive it, and young, fresh green leaves appear again. No plant could be growing under

land or for placing among low-growing shrubs.

CAMASSIA.—Here we have a family of hardy plants which may be used in the same way as the preceding. Once fairly established they are a joy for years; in fact, the longer they remain undisturbed the better they are, although, of course, no plant is endowed with indefinite life. *C. esculenta* has long been an inhabitant of English gardens, and was once more in favour than at the present time. Individually it is not impressive. Like many bulbous-rooted plants, it must be planted in colonies to be effective. This species should do in Grass where it does not grow over-rank. The finest member

The lower lake at Sheffield Park, Sussex. From a photograph by G. A. Champion.

country all tending to make the scene as charming as man's planting and Nature's gifts can make it.

It is not so much the fine collection of things I want to speak of as the landscape beauty. The gardening fraternity are apt to over-plant and to think very little of breadth, grouping, or repose. Therefore, broad sheets of water, such as are here, are a great aid in giving light, air, and space. Hence the reason for making the most of them. The improvements effected by Mr. Soames are very striking in every way and all parts.

W.

Improving lawn (A. L.).—Have all the weeds and Daisies removed from the lawn in March, then top-dress with a rich, light soil

worse conditions than this Asphodel does with me. It is close to a Douglas Fir, the roots of which fill the soil for several square yards, and is therefore extremely poor and dust-dry at times in the summer. In spite of these adverse conditions a plant has lived and bloomed for some years and has ever increased. *Asphodelus ramosus* is quite a different plant, and possesses a certain amount of effective beauty which is best displayed in association with other things. It is a good plant for the mixed border. This is supposed to be the oft-quoted Asphodel of Shakespeare. Very indifferent as to the character of the soil, and able to take care of themselves when in intimate association with other things, these Asphodels are suitable for the wood-

of the family is *C. Cusicki*, a very distinct plant with a certain nobility of growth. It is worthy of a good place in any garden where hardy flowers get good treatment.

CHELONE BARBATA is first cousin to the Pentstemons, and, like them, in the majority of soils is best treated as a biennial. It exhibits the same fine decorative qualities, and the same constitutional defects, as those much-prized ornaments of the outdoor garden. It is a curious fact that some hardy plants which cannot endure without loss of vitality the heavy rainfall which frequently characterises the English winters, are equally adversely affected by very dry periods. Frequent renewal is the only thing to do in such cases. In its nature *Chelone barbata*

bears such a close resemblance to the Pentstemons that the only safe way is to sow annually, thereby being always in command of plants which, by reason of youthful vigour, not lowered by a season of flower production under trying weather conditions, will take the place of those which have their vitality sapped by prolonged periods of heat and drought. Seeds sown early in the year will make strong-blooming plants for the following season if well cultivated. If sown, as I have often done, some time during the summer, they can remain in the seed-pans until the following spring. Wintered in a cool-house or frame they will be very hard, and can be put out in March or early in April, which will give them a long season of growth, and they will make fine specimens which, in the heyday of their youthful vigour and luxuriance, will yield a rich reward in floral beauty for all pains taken.

ERIGERON AURANTIACUS is in many soils disappointing in the same way as the preceding, a season of good flower production being followed by a collapse. I have an idea that this Erigeron grows naturally among herbage in the same way as *Gentiana verna* and some other native plants of very dwarf stature, their welfare to a large extent depending on the protection to the roots and crowns thus afforded. There are many alpine plants that could be induced to thrive permanently with us in this way if we could command the right kind of herbage, but as a rule this grows too rank. The kind that covers our Surrey commons, where the soil is very light and poor, would be ideal for naturalising such things. For the generality of gardens frequent seed sowing must be practised. In low-lying localities this Erigeron must be grown in the rock garden. J. CORNHILL.

LILIUM BROWNI AND NEARLY-ALLIED KINDS.

WHAT is *Lilium Brownii*, and whence does it come? Like the Nankeen Lily (*Lilium testaceum*), its history seems to be obscure. All that is known is that it was distributed by a nurseryman named Brown, of Slough, somewhere about 1830. It would probably soon have died out in this country, but it was taken in hand by the Dutch growers, who found the conditions prevailing in their country suit this Lily. At all events, considerable numbers of it are sent here every year from Holland in the shape of large, firm bulbs that can be depended upon to flower well the first season after planting.

The "Kew Hand-list" gives the native country of *Lilium Brownii* as China and Japan. This may be, yet out of the vast importations from China which we have received within the last dozen years or more I have not seen a Lily that would be confounded with the Dutch-grown species, which I have known for nearly half a century, long before the Chinese forms made their appearance in this country. The "Kew Hand-list" gives two varieties of *Lilium Brownii*—namely, *Chloraster* and *platyphyllum*. Neither of these is, however, in general cultivation, while *Lilium Brownii leucanthum*, which first flowered at Kew in 1894, and formed the subject of a coloured plate in *The Garden*, Vol. 47, is not included. At the time of its flowering it was described as having a particularly good constitution, but something would appear to have happened since then. In the bulbils from the axils of the leaves, and its general appearance, this form seems to have a considerable affinity with the Burmese *Lilium sulphureum*, but it is considerably less in stature. This

brings me to one of the newest and best of the Brownii group, namely,

LILIUM REGALE, a very free-flowering species. In this the centre of the flower is flushed with yellow, shading to white at the edges, while externally it is marked with brown towards the base, changing to rose at the tips. The anthers are yellowish. This Lily was first distributed as *Lilium myriophyllum*, and as such was given an award of merit. Last year, at Holland Park, it received a first-class certificate. Apart from its beauty, the robust constitution of *Lilium regale* is also a most valuable asset.

LILIUM SARGENTÆ is later in flowering and of taller growth than *L. regale*, with which, however, it has many features in common. Both prefer a good loamy soil for their successful culture. One other member of the Brownii group must be mentioned. This is the Lily which, in the "Kew Hand-list" is referred to as

LILIUM JAPONICUM COLCHESTERI, the name of odorum being given as a synonym. This Lily is certainly widely removed from *L. japonicum* (*L. Kramerii* of gardens), and it undoubtedly belongs to the Brownii class. A few years ago a bed of *Colchesteri* at Kew was labelled Brownii during the whole of its flowering period. Beside this the bulbs sent here from Japan under the name of Brownii are usually those of *Colchesteri*. This last differs from the Dutch Brownii in the foliage being broader and of a much thinner texture, while the flowers are shorter, less stained with chocolate on the exterior, and yellowish within, instead of the ivory-white of *L. Brownii* itself. As *Colchesteri* is so dissimilar from *L. Kramerii* the older name of odorum would appear to be the correct one. K. R. W.

FLOWERING PLANTS UNDER PERGOLA.

IN my garden I have a pergola sloping down the terraced hillside. From the early summer until the late autumn the top of the pergola is covered with the canes and foliage of *Wichurajana* Roses, which bloom freely, and at such a time there is considerable shade beneath the pergola. On either side of the walk down the pergola there is provision for growing flowers, but the loss of light after midsummer is so great that few flowering perennials, or even annuals, do well. I should be much obliged for any suggestions as to how best to treat the beds beneath the pergola, so as to make them gay and attractive, if not throughout the year, at least during as many months as possible. Would you kindly tell me what flowering plants do well in partial shade? What I could plant so as to obtain flowers in the early spring before the Roses are in full leaf? Would *Irises* grow well in such circumstances? *Daffodils*, presumably, could be planted, also *Polyanthuses* and *Anemones*.—DEVONIAN.

[Provided the soil was suitably prepared for their reception, there are many plants which would grow quite well beneath the shade. We take it the side light is available, which would be helpful in its way. You give us no idea of the size of the pergola—its length or width—so that we can only reply in general terms. In any case you might freely indulge in such things as *Snowdrops*, *Chionodoxas*, *Anemone blanda*, **Adonis amurensis*, **Lenten Roses*, **Hepaticas*, *Narcissus Queen of Spain*, *N. pallidus præcox*, and other *Daffodils*; also *Muscari conicum*, which would provide pretty colour patches from February onwards to May, and before the Roses make much headway. After that time such **Liliums* as *candidum*, *eroceum*, *umbellatum* in variety, *Hansonii*, *testaceum*, *chalcidonicum*, *pomponium*, *pyrenaicum*, *odorum*, and others arranged in groups at intervals would carry on the display, assisted by Spanish and English *Irises* in variety. The taller, bearded, or **Flag*

Irises we would only introduce if ample room existed, and in such case they would be most effective. **Montbretias* in moderation might also be good. The general run of hardy perennial border plants should not find a place, though a set of the more distinct **Heucheras* might be added with advantage, or the brilliant **Transvaal Daisy* (*Gerbera Jamesoni*), which should be hardy with you in the open. These, with *Colchicums*, such as *Crocuses* as *speciosus*, *zonatus*, and others, and the red and white *Cyclamen neapolitanum*, which is valuable also for its foliage for months on end, would provide not only variety and beauty but a fairly long season of flowering to boot. Those marked by an asterisk could be planted now, the remainder could be dealt with in autumn.]

NOTES AND REPLIES.

CROCUS BORYI, var. *marathonisius*.—In his "Monograph of the Genus *Crocus*," Mr. George Maw figures flowers of *Crocus Boryi* in bloom in November. He suggests that from the lateness of its flowering this lovely *Crocus* "is best grown to advantage under the protection of a cold frame." It stands winter weather wonderfully well without any protection, but, undoubtedly, the shelter of the frame will induce it to bloom earlier, and to last longer, than in the open. The early frosts retarded *C. Boryi* and its variety *marathonisius*, and the latter could only be said to come properly into flower as late as January 9. It differs but little from the typical *C. Boryi*, which has white flowers with a patch of yellow at the throat and the base of the exterior, though an occasional variety has the outer segments delicately lined with lilac. Some authorities have given *C. marathonisius* specific rank under that name, but Maw informs us that the only difference he can observe between it and the typical *Boryi* is that the stigmata are less branching and only reach to the level of the summit of the anthers. This distinction is borne out by a study of the plants as grown here. One can, therefore, hardly quarrel with Maw's classing it with *C. Boryi* as only a variety. I may say that my plants are in the open without protection, and in a fairly sheltered position are standing well.—S. ARNOTT.

SWEET PEAS.—A sowing of Sweet Peas will be made at once in 3-inch pots, sowing two seeds in each, placing the pots in a moderately warm pit, and covering with boards to protect the seeds from mice till the seedlings are through the soil. The seedlings must be grown in very cool conditions from the first, admitting plenty of fresh air whenever the weather permits, and keeping them near to the roof-glass. Support the shoots with small twigs, which should be placed in position when the plants are very young. The seedlings will eventually be hardened off and placed in a cold frame till planting-time arrives. The ground must be prepared as soon as possible, both for the early and later batches. Deep cultivation and plenty of well-decomposed cow-manure are necessary to obtain the best results. At the final preparation of the ground a liberal quantity of soot and wood-ashes will be scattered over the surface.—F. W. GALLOP.

NEW INDEX AND BINDING CASES FOR COMPLETED VOLUME.—The Index to Volume XXXVII. of GARDENING ILLUSTRATED is now ready (price 3d., post free 3½d.). The Binding Case for the same volume is also available (price 1s. 6d., by post 1s. 9d.). The Index and Binding Case can be obtained from any newsagent, or from the Publisher, 63, Lincoln's Inn Fields, London, W.C. If ordered together, the price of the Index and Binding Case is 2s., post free.

GARDEN PESTS AND FRIENDS.

DISEASES OF PEAS.

POWDERY MILDEW.

(ERYSIPIHE POLYGONI, D.C.)

DURING a comparatively dry, bright season the leaves of Peas often show sickly, yellowish-green blotches, which gradually increase in size until the whole of the foliage changes to a yellow colour and soon wilts and dries, though the leaflets, as a rule, do not fall. If the under-surface of a leaf, just beginning to show yellow patches, is carefully examined, the discoloured patches will be seen to be covered with a delicate whitish mildew, which gradually spreads over the entire surface, or even over the upper surface as well. When badly attacked, a row of Peas presents the appearance of having been whitewashed — leaves, stems, and pods being equally covered with the mildew. In such cases the plants soon die outright,

These spherical winter-fruits enclose spores or reproductive bodies. They remain unchanged until the following spring, when they decay and the spores are liberated. These spores infect young Pea plants and give origin to the vegetative stage of the fungus (mycelium), which first produces the crop of summer spores. Powdery mildew also attacks various kinds of Vetches, both cultivated and wild, and several of our commonest weeds belonging to widely-separated families of plants.

METHODS OF CONTROL.—Spraying is practically ineffective unless begun sufficiently early. It should be begun before the disease appears in June or July, especially if the weather is dry and hot.

Liver of sulphur, used at a strength of 1 oz. in 4 gallons of water, is preferable to Bordeaux mixture for this disease. As the disease is not apparently carried in the seed, the infection must be derived from some outside source, such as from diseased

son. The winter-spores are produced on the vegetative form of the fungus (mycelium) which is present in the tissues of the dead leaves, and cannot be seen from the surface. These winter-spores, as usual, remain in a resting or unchanged condition until the following spring, when they germinate and infect Peas and allied plants.

Pea mildew also attacks both wild and cultivated Vetches, and many wild plants belonging to the Pea family.

METHODS OF CONTROL.—The first infection in spring can only be due to winter-spores, and hence the necessity for destroying all diseased material. Burning is the only certain method of accomplishing this object, as the winter-spores pass through the intestinal canal of an animal without injury. Spring infection is often due to fragments of diseased leaves falling to the ground, where they decay and liberate the winter-spores, which remain on the ground until the following spring.

The upper lake, Sheffield Park. (See page 57.)

and in every instance the injury caused to the foliage affects the crop, the injury being in proportion to the amount of mildew present.

When examined under a microscope the mildew is seen to consist of myriads of reproductive bodies (conidia), which are produced in chains, but soon become free from each other and form a dense white mass on the surface of the leaf, suggesting the idea that it had been sprinkled with flour. These conidia are summer-spores, which are capable of germination at the moment of maturity; they are scattered by wind, rain, insects, etc., and in this way spread the disease. Later in the season, when the infected plants are dying, a second form of fruit, known as winter-fruit, is produced from the same vegetative portion of the fungus (mycelium) which had previously given origin to the summer-fruit. The winter-fruit first appears in the form of minute yellow balls which eventually become dark brown or blackish, and are often present in myriads on the dead leaves.

Pea-straw, or weeds capable of harbouring the parasite. The straw should, therefore, be burnt and weeds kept down.

PEA MILDEW.

(PERONOSPORA VICIÆ, De Bary.)

This mildew is liable to be confounded, by the casual observer, with the powdery mildew described above, but belongs to a totally different group of fungi, and requires different treatment. The leaves first become covered with a delicate white mould, which soon changes to a pale pinkish-grey colour, and may pass unnoticed until its presence is indicated by the wilting and yellowing of the leaves. The powdery appearance of the mould, so characteristic of powdery mildew, is entirely absent, and, inspected with a good pocket-lens, the mildew is seen to consist of myriads of upright stems, which bear numerous branches at the tip, the tip of each branchlet bearing a single summer-spore (conidium). It is these summer-spores, dispersed by various agents, that spread the disease during the growing sea-

Rotation of crops would in this instance be desirable.

When the disease is present spraying with half-strength Bordeaux mixture* should be resorted to. Liver of sulphur is much less satisfactory in its action on the mildews proper.—*Leaflet No. 287, Board of Agriculture and Fisheries.*

(To be continued.)

Looking through the seed lists.—In the past I think we have been too much under the influence of Germany in the matter of garden seeds. Our own people are now finding out that they can do without the Germans, as, aided by our colonies, we can produce as good, if not better, seeds than the Germans. Some of our lists of various things are getting too long—longer than is necessary or desirable. The lists of names of Sweet Peas on offer are, I think, absurd, as they make the work of selection very difficult. The same difficulty occurs in many other things; Peas, for instance, and Tomatoes. Of the latter there are more than sixty names in a list before me. It is confusing, and really not necessary, as the best might easily be included in a list of a dozen names or so.—E. H.

* 6 lb. copper sulphate or bluestone (98 per cent. pure) and 3 lb. quicklime to 100 gallons of water.

VEGETABLES.

CHICORY AS A WINTER SALAD.

WHEN Lettuces and other things are scarce there is never any difficulty in having plenty of Chicory, and it is to a large extent a substitute for both Lettuce and Endive. The Chicory is a hardy plant, and if sown in time the roots will be strong, and, like Seakale, may be taken up and forced when wanted. When grown for blanching common Chicory is usually sown during May and June. If sown sooner it goes to seed. The object of the cultivator should be to get good strong roots capable of producing a large number of leaves when they come to be forced. The plant is not particular as to situation, but it should have a rather light and moderately rich and deep soil. Being a tap-rooter, like the Carrot, it sends its Carrot-shaped roots straight down, and when it can do so freely the plants are always much stronger. The ground should be deeply dug with a spade or fork or trenched (if it has not been done in the winter-time), and the seed should be sown at the same time in drills not less than 15 inches apart; and when they can be well handled the seedlings should be thinned out to 1 foot apart in the rows. After this the only attention they require will be hoeing between the rows and watering in dry weather till November or December, when the plants will have shed their leaves and be ready to take up for forcing. The

FORCING OF THE ROOTS is an easy matter. When the leaves have decayed a number of roots should be taken up and laid in soil in some cold shed or other structure where they will not be frozen, and from this store they can be removed in batches for forcing as wanted. This is merely a precaution in case of severe frost or snow setting in and preventing them being lifted from the beds, where the main lot should be allowed to remain. The quantity of roots to be forced at a time will depend upon the demand for the salad. For a small family as many roots as can be put into a 12-inch pot will be sufficient at one time. Whether the roots are forced in a bed, or in pots or boxes, they should be buried up to within an inch of their crowns in light soil of any kind, watered, and placed in a temperature of from 50 degs. to 60 degs., and be kept in the dark. If a dark shed or cellar be not available, the crowns may be covered with an inverted flower-pot or box, which will do quite as well. In this way Chicory is sometimes forced in a kitchen. The leaves soon push out, and they should be cut when they are young and tender, and always just before they are required for salad, for which purpose they are prepared like Lettuce or Endive. The roots will push out leaves a second and even a third time after being cut, but the growth is weaker every time, and the better plan will be to introduce a succession of fresh roots before the supply becomes exhausted.

NOTES AND REPLIES.

Two early dwarf Peas.—The dwarf Peas of recent introduction are now little inferior to the taller growers. This is a great gain, as they are a vast improvement on the old small, white, round-seeded Peas. I have found it advantageous to sow these dwarf varieties quite close. Eighteen inches or 2 feet between the rows will suffice if such a kind as King of the Dwarfs, an excellent variety only 12 inches to 15 inches in height, is used. Considering its height it bears a really good pod, and is remark-

ably early. Reading Wonder, the other variety, is probably less known, though equally valuable, and like it as regards quality. This is an ideal variety for a small or narrow border, being of compact growth and producing good pods, mostly in pairs, with eight to nine Peas in a pod, and remarkably early. Last season I saw this in cold frames, and grown thus it gave excellent results. Sown in January there were excellent dishes in a little over three months from date of sowing.—W. F.

Early Broad Beans.—Of late years some valuable additions have been made to the early Longpod Beans, and one or two to the later Windsor section. After repeated trials I have found as regards earliness, and, of course, hardness also, no variety superior to the old Mazagan, or the later but useful Dwarf Cluster. I prefer the Mazagan, but both are equally good for sowing this month (January), should the weather be suitable, or as early in February as the soil is in a workable condition. For many years I sowed the Mazagan in November, and with a mild winter there is a gain. It well repays those who want Broad Beans as early as possible to sow in frames or in boxes under glass. It is surprising how quickly the above variety blossoms even when the plant is quite dwarf. The Mazagan is harder than the larger green Longpod. If possible, give a warm, sloping border. These early varieties may be planted closer than the larger and later varieties. The reason I have included the Dwarf Cluster is on account of its dwarfness. When sown somewhat close the plants protect each other. Where the soil is at all heavy I have found it a good plan to make it more suitable by a liberal addition of burnt garden refuse or wood ashes. The Beans of the above varieties, though small, are of excellent quality.—F. K.

Early Peas.—As the soil is too wet and cold for Peas to be sown outdoors at present—and will be until the month of February is well advanced—a sowing of a first early variety will be made and raised under glass as soon as the seeds come to hand. As pots will be the more expeditious way of raising the plants pots 5 inches in diameter will be used for the purpose. One crock in each with a few flaky pieces of loam on top will suffice for drainage. When the time arrives for planting to be done root-disturbance is then reduced to a minimum. The compost will consist mainly of good, sound loam with a small quantity of leaf-mould and spent Mushroom manure mixed with it. The pots will be placed in a cold pit and no artificial warmth used to hasten either germination of the seeds or to forward growth afterwards. Even then the plants will be quite forward enough by the time planting can be done. Other methods of raising early Peas are to sow either in boxes or on turves, which, when labour admits of their being cut and prepared, are, perhaps, all things considered, the better means to employ, as not only do the roots thoroughly permeate the turf, which is of the greatest assistance in sustaining the plants until the roots get a grip of the soil when first planted, but the turf itself assists in improving the condition of the staple.—G. P. K.

Good forcing Lettuce.—Those who value tender salad in the early spring will find it a good plan to sow a box of seed in January. I have found such varieties as Commodore Nutt and Tom Thumb the best for the earliest spring supplies, though where there is no lack of room such kinds as Golden Ball and Golden Queen are excellent, but a little longer in hearting than the first named. Seed sown

on rich, light soil, and placed in a warm frame, soon germinates, and from this period the plants should be grown near the glass. I have often sown a little seed in a frame made up with leaves and warm litter some time in advance of sowing, and thus one gets strong plants. The seedlings may be planted out or grown in boxes for the first supply. If planted out in frames a little bottom heat at the start is of much benefit, and good material of the small early Cabbage forms noted above may be had by Easter. Much depends upon the treatment of the seedlings in their early stages of growth. In all cases avoid excess of moisture, as this causes damping. With a deficiency of frames or heating material I have found box culture very serviceable, as the boxes can be moved from house to house.—W. F.

Early Peas and Beans.—Every large seed firm has its own selected varieties of Peas, etc., and one cannot go far wrong in planting those they recommend. Among Peas, we may include, if we want dwarfness, The Sherwood, Ideal, Early Bird, and Gradus, and as soon as the weather is suitable make a sowing at the foot of a south wall as well as in pots to come on in a cool-house to be ready to go out in treuches in March when the weather is settled. Protect for a time with evergreen branches thrust into the ground beside the plants. A sowing of second early Peas may be made shortly, and may include such kinds as Daisy, Senator, and Telephone, sowing thinly. I draw 6-inch drills, and drop the seed about 2 inches apart in sowing the early kinds, and give more room as the season advances. Early Beans should include Beck's Dwarf Green Gem; and as Beans always transplant well, plant the first lot in boxes under glass, harden off, and plant out in March.—E. H.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM JANUARY 14TH.—*Winter Sweet* (*Chimonanthus fragrans*), *Garrya elliptica*, *Hamamelis arborca*, *Genista hirsuta*, *Jasminum nudiflorum*, *Coronilla glauca*, *Forsythia spectabilis*, *Edgeworthia chrysantha*, *Daphne Dauphini*, *D. Laureola*, *D. Mezereum*, *Periwinkles*, *Berberis japonica*, *Andromeda floribunda*, *Polygala Chamabuxus purpurea*, *Prostrate Rosemary*, *Parrotia persica*, *Laurustinus* (various), *Strawberry-tree*, *Erica herbacea carnea* (in several varieties), *E. alpina*, *E. mediterranea hybrida*, *E. m. glauca*, *Crocus Imperati*, *Aconites*, *Carpathian Snowflake*, *Winter Heliotrope*, *Christmas and Lenten Roses* (in variety), *Snowdrops* (in variety), *Aubrietias*, *Polyanthus* (various), *Cyclamen Coum*, *Violets*, *Tufted Pansies*, *Triteleia uniflora*, *Anemone coronaria*, *Great Pilewort* (*Ficaria grandiflora*), *Megasca*, *Primroses*, *Algerian Iris* (*I. unguicularis*).

WORK OF THE WEEK.—Lapagerias promise to be quite a success out-of-doors, especially on north and east walls. Having a favourable position clear, some of the rosy form have been planted out, plenty of leaf-soil and sand being worked into the soil. *Rhododendron Nobleanum* and *R. ciliatum* are two very early-flowering kinds. As their blossoms are liable to be damaged a very sheltered position has been found for them out of the reach of cutting winds. The soil is of a sandy nature and slopes to the south-east. A good-sized group of each kind has been put out. *Escallonia montevidensis* has been planted at the foot of a wooden fence. More Michaelmas Daisies have been transferred to the waterside to make room for some groups of *Eulalia japonica viridis*, *E. japonica gracillima*, and *Gynerium argenteum Bertini*. These are contiguous to a large existing group of Pampas Grasses and other Reeds, so that the whole plantation may be seen from various directions. *Exochorda Giraladiana*, *Syringa Sweginzowi*, and *Polygonum*

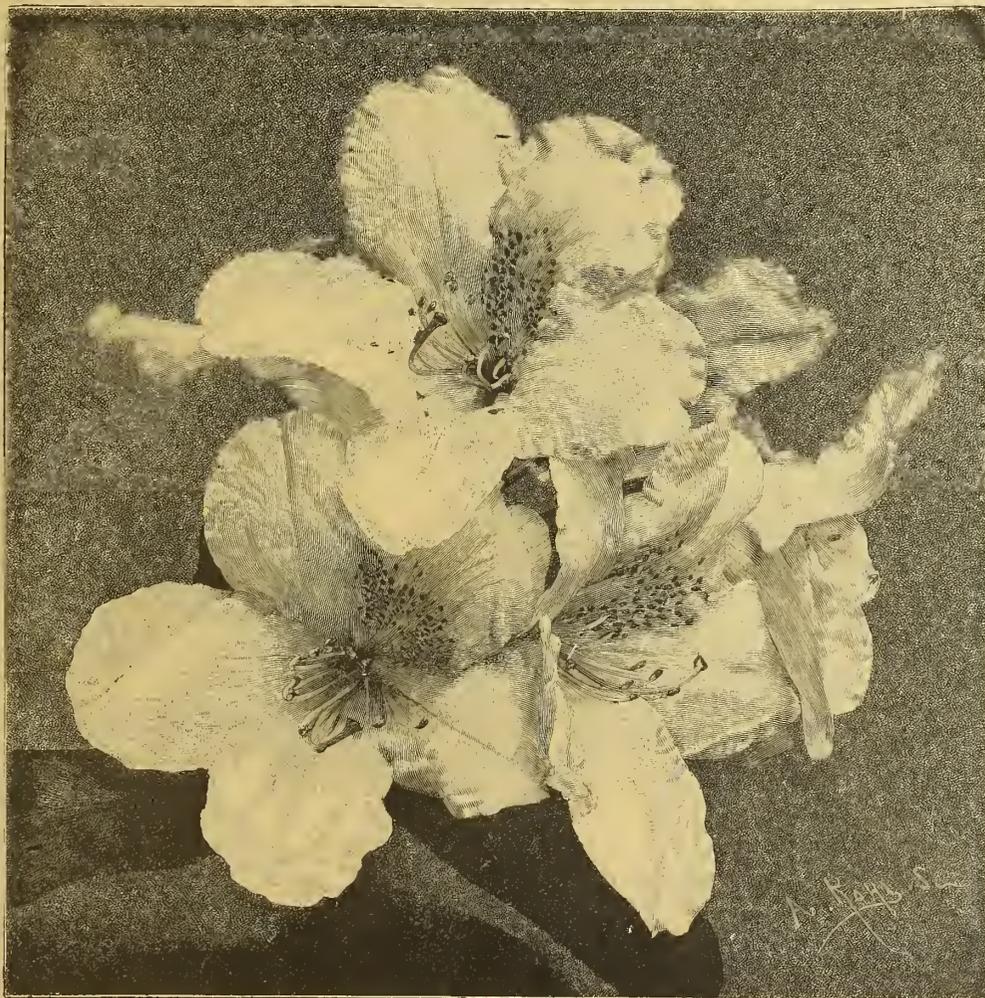

Auberti have been planted out, the last on Holly-trees and fences. Rose Hiawatha has been treated likewise. Hepatica triloba, H. triloba rosea, H. angulosa major, and its rosy-pink variety, have been added to a previously-made plantation of these early-spring flowers. A group of Davidia involucreta has been growing in a rather shaded position, and it was decided to move a few of the plants to another part of the garden where they will be fully exposed to the sun for most of the day. A dense mass of roots had been formed during the little time they have been planted here. A group of Larkspurs, chiefly seedlings, has been planted near a newly-made entrance. Oenothera speciosa grandiflora, Inula glandulosa, some new varieties of Day Lilies, and a White Flax have been added

SOUTHERN COUNTIES.

Late Grapes.—As the vinery is now needed for storing various kinds of plants for a time, and as the Grapes will now keep better off the Vines, the remainder of the crop will be cut and bottled. To do this, not only is fine weather a necessity, but three pairs of hands are required, one to cut the bunches and examine them thoroughly, so that they may be free from decaying berries, another to carry them carefully to the Grape-room, or whatever place is for the time to be used as such, and the third to insert the ends of the laterals into the bottles. The bottles must be so arranged that the bunches hang clear of each other, and so secured that they cannot move out of position. Darkness and

usual cleansing, both of Vines and structure, can then be undertaken at any convenient moment. That the Vines may get as thorough a rest as under the circumstances is possible, the ventilators will be opened to their widest extent whenever the weather is favourable.

Early Peach-house.—Climatic conditions in the south have been such that little or no fire-heat has been required to forward the trees to the stage when the buds swell apace and begin to show the colour of the petals, which means that the temperature must now be advanced another 5 degs. at night and from 5 degs. to 10 degs. by day. If necessary the border should be again watered before the blooms begin to unfold, and the house fumed whether aphid is present or not. Neglect of both the last-

Rhododendron Manglesi.

to the mixed border, while two varieties of the Maiden Pink have found a place on a raised border well exposed to the sun. A group of Aucubas has been lifted and transferred to the boundary of the Heath garden, where they are intended to block out some unsightly out-buildings, at the same time forming a groundwork to over-hanging Pine-trees. A few hybrid Clematises have been planted to ramble among Holly bushes. Pruning is being pushed on, the weather being very mild. Vines, Passion Flowers, and Solanum jasminoides have been dealt with, removing, in the case of the two latter, all thin, unripened wood, and training out that required for furnishing bare spaces. The forking over of shrubberies is being pushed along at every favourable opportunity.

E. M.

Sussex.

dry air being essential for the keeping of the Grapes, light must be excluded and any damp caused by the spilling of water while bottling was going on dispelled by the use of a little artificial heat. After this a steady temperature of 50 degs. suffices, and the admission of air regulated according to outside weather conditions, closing the ventilators or windows when frost, rain, or fog prevails, and opening them to a less or greater extent as may be necessary when it is fine and dry.

Pruning will be done directly the Grapes have been bottled. The wood has ripened splendidly, but as so much fire-heat has been used during the winter the wounds will, as is customary, be dressed with "knotting," which will, at any rate, prevent bleeding either now or when the Vines come to be started later on. The

named details oftentimes means an indifferent set and an attack of fly before the trees can, owing to their still being in bloom, be safely fumed. Up to the time of the expanding of the blossoms damping down and syringing are continued as before, it being more freely indulged in when the morning is bright and the temperature, with the aid of sun-heat, standing at 70 degs. to 75 degs. at closing time. When the flowers begin to expand, generally drier conditions are, for the time being, maintained, but a dry, parched atmosphere is never allowed, as the floors are damped down when air is admitted on fine mornings, and again when closing for the day. As a free circulation of air is necessary for the ripening and dispersion of pollen the maximum amount of ventilation permissible is afforded by the time that it is requisite to carry out the fertilisation of

the flowers, or about mid-day. Bees perform their due share of this process if they can gain ingress to the house, but to make doubly sure of a good set the flowers are lightly touched with a rabbit's tail tied to a stick. The trees are also given a gentle shake each day on the completion of pollination. Care is also taken not to extend the fertilisation beyond the period when individual flowers give signs, by the fading and dropping of the petals, that the process is complete, as doing so is apt to damage the stigmas.

Pot Strawberries.—A shelf in the early Peach-house furnishes an excellent position on which to place pot Strawberries just coming into flower, as the conditions are suited to both until the fruits of the latter are set and swelling off, when they need a warmer temperature in which to develop size and mature. Hand setting of the blossoms being a necessity, this is best performed at the time the Peaches are receiving attention with the same kind of, but separate, implement. Keeping the soil slightly on the dry side tends to promote speedy and perfect setting, but care has to be taken to see this is not carried to excess, otherwise the balls contract and leave the sides of the pots, which no after attention will remedy, to say nothing of the labour that will be consumed in watering afterwards as a result. The taking in of the first batch of plants as indicated allows of another relay being brought in from their winter quarters to be started after undergoing a course of preparation in the way of picking off dead leaves, examining the drainage, scrubbing the pots, removing a little of the surface soil, and making good with a top-dressing containing a stimulant. Clay's Fertiliser was used for this purpose last season with such excellent results that it will again be employed. Extra vigour of the flower-spikes follows the use of this stimulant.

Spring Cabbages.—Harbinger has made such progress that, unless severe weather should intervene, heads for cutting will be available by the middle of—if not earlier—next month. Other varieties, such as *Ellam*, *Matchless*, *Flower of Spring*, and *Ellam's* are, if not so advanced, in an equally satisfactory condition, and the hoe will be run through them and a little soil drawn up to the plants on either side to steady and protect them. A little later sulphate of ammonia will be strewed between the rows at the rate of 1 oz. per square yard, and lightly hoed in. A large and later breadth planted to form a succession to the foregoing will now have the soil stirred between them, as the surface in this case has become beaten down by the recent heavy rains. Young plants raised last September and intended for getting out next month to supply a still further succession have wintered well, and have just been hoed through and relieved of weeds.

Border Chrysanthemums.—Owing to shortage of skilled labour the old stools have been lifted and pulled to pieces in lieu of propagating from cuttings, as has usually been done. The best portions of each stool have been potted and placed indoors to give them a start. As soon as they commence making new roots and pushing up growth all will be moved to a cold pit. It is hoped that the plants will be ready for planting out early in March and so save further labour in watering, etc.

Chrysanthemums for pots.—The propagation of Japanese and single varieties for pots will now be commenced. An improvised case is fitted up for this purpose on the front stage of a vinery. This consists of 9-inch boards, 1 inch thick, placed

on edge to form the back and front, the ends being of boards of the same dimensions. The width of the case is 2 feet, and large sheets of glass, which reach from one side to the other, render it sufficiently air-tight. The stage being covered with ashes a cool and moist base is thus provided on which to stand the cutting pots, 3½-inches in diameter. The glass is removed each morning and wiped dry with a cloth. A. W.

MIDLAND COUNTIES.

Vineries.—The pruning of all Vines should now be completed. Thoroughly cleanse the rods with a mild insecticide, such as Gishurst compound. I do not advise the scraping of the rods. The loose bark may be carefully removed with the hand, and the insecticide worked well into the crevices of the bark by means of a soft scrubbing brush. If the Vines have been badly attacked by mildew or red-spider close the ventilators and vaporise two or three times with a nicotine and sulphur compound. Having cleansed the Vines and the house, give the walls a coating of lime-wash, remove any loose or exhausted soil from the surface of the borders, and apply a good top-dressing of rich loam mixed with some fertiliser and a little lime-rubble. Tread the new soil firmly and cover it with a mulch of manure from a spent Mushroom-bed.

Hardy fruit.—Owing to the mild weather the buds on many fruit-trees are becoming very prominent. Pruning and training having been completed (with the exception of Peach-trees) spraying must be seen to. Carefully rake up all prunings, remove the surface soil from badly-affected trees, and convey them to the fire-heap. American blight—the worst pest that attacks Apple-trees—is one of the most difficult to eradicate. Badly-attacked trees should have the infested parts carefully dressed with undiluted paraffin, very carefully working it in with a small painter's brush. This requires great care and must be done whilst the trees are quite dormant. The stems and main branches should be thoroughly scrubbed with a strong solution of Gishurst compound. After this is done all trees should be thoroughly sprayed with caustic soda-wash, or one of the effective proprietary washes that can be bought ready mixed. I have found V. 1 Fluid for winter spraying, and V. 2 Fluid for summer spraying, safe and effectual against all pests. The best way of applying these and other sprays is by means of a knapsack sprayer, but where only a small number of trees has to be sprayed an ordinary syringe, with a spraying-nozzle attached, will answer.

Heliotropes as standards.—Plants of Heliotrope intended for training as standards may be raised from cuttings inserted singly in thumb pots and rooted in a frame in the propagating-house. The frame should be opened slightly to admit air, otherwise the cuttings are liable to damp off as they are susceptible to injury from excessive atmospheric moisture. After the cuttings are rooted they should be taken out of the frame, but may still be stood in the propagating-house. When they have filled the small pots with roots they should be potted into 4½-inch pots, using a compost of good loam and leaf-mould with a little sand. Allow the main stems to develop until they have reached a suitable height. Repot into 7-inch pots as soon as ready, and transfer to a house having an intermediate temperature. Pinch out any flowers that develop to throw the energies of the plant into making growth. The compost for the final potting should consist of loam, leaf-

mould, and well-decayed cow-manure, adding a little sharp sand and bone-meal. An important point in the cultivation of Heliotropes in winter is to prevent the plants receiving a chill.

Christmas Rose (*Helleborus niger*).—A batch of Christmas Roses that are in an unsatisfactory condition will now be divided and transplanted. A rich bed, about 2 feet 6 inches deep, has been prepared for the plants. With the lower foot of soil a heavy dressing of cow-manure was incorporated, as the Hellebores are partial to a cool and sustaining sub-soil. Some well-rotted manure is also added to the upper stratum. Large clumps should never be transplanted in their entirety, as such a course often results in the death of the plants, however carefully the removal is effected. When the clump is lifted it should be placed in tepid water, and when the soil around the root is well moistened this may be washed off with a single-jet syringe. When the roots are entirely free from soil the clump may be divided, separating the roots by hand and cutting the crowns apart with a sharp knife. A portion with three crowns is quite large enough for a single plant. These divisions should then be planted 18 inches apart, using around the plants a few handfuls of fibrous loam and leaf-mould, no manure being allowed to come into direct contact with the roots. A sheltered position is best adapted for this plant, one partially shaded by trees at some little distance being admirably suited to its requirements. A mulch of well-decayed manure and leaf-mould in early spring, and plentiful supplies of water during hot weather, will promote the vigour of the plants.

Perennial Lobelias.—The stock plants which have been wintered in frames are now making growth, and if any increase is required the young growths may be taken with a few roots and potted into 5-inch pots. If placed in a temperature of 55 degs. they will soon become established, and may then be removed to a cold frame, the protection of a mat being sufficient to keep out frost. Watering must be carefully done and ventilation given freely in fine weather. This is all the attention they will require previous to planting them out.

Cabbage.—The autumn plantations are looking remarkably well, but having grown so freely in consequence of the mild weather they would suffer severely in case of sharp frost. A dressing of soot has just been applied and the ground stirred between the rows with a digging fork to the depth of 3 inches. Where there appears a likelihood of there being a scarcity of spring Cabbage a small quantity of seed of an early-maturing variety had better be sown now, raising them in gentle heat. Such plants may be expected to produce heads fit for use early in the spring.

Spinach sown last autumn has done well here this season, and there is little likelihood of a scarcity before the spring or February-sown crops are available. The first opportunity will be taken to sow a few rows on a warm border.

Onions raised from seed sown in boxes at the beginning of the year are making good progress, and will shortly need pricking out into boxes filled with three parts fibrous loam, one part leaf-soil, and one part spent Mushroom manure, adding a dusting of bone-meal, soot, and sufficient sand to keep the soil porous. The soil should be in a moderately dry condition, and be made firm in the boxes. Prick out the plants at a distance of 3 inches apart. Stand the boxes in a light position in an atmospheric temperature of from 50 degs. to 55 degs. If not

already done, the land should now be prepared for planting the seedlings. Select an open situation and ground that has been deeply cultivated and in a good condition generally. Trench the land as soon as possible and allow it to remain in a rough condition until March, when a good dressing of soot should be forked into it. About the middle of April, or later if the weather is unfavourable, the plants may be put out.

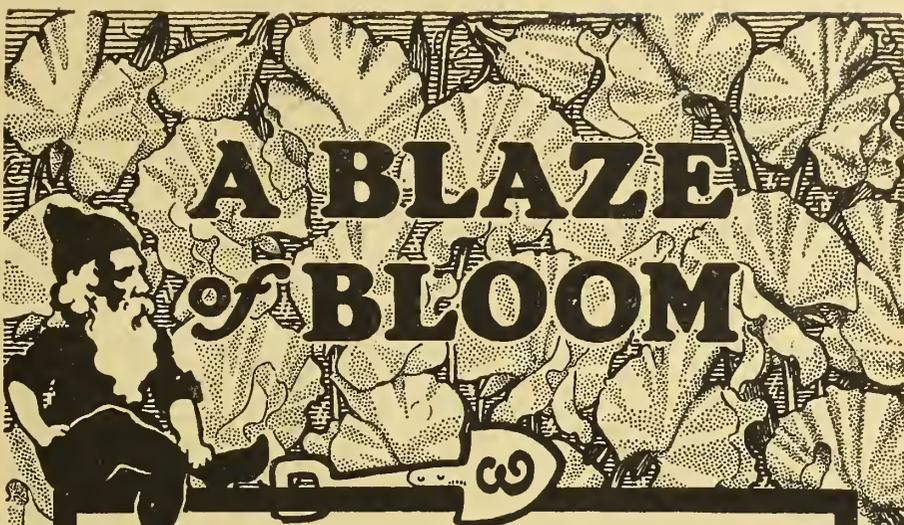

F. W. GALLOP.

SCOTLAND.

Hardy flower borders.—In the course of the week some progress was made with the annual turning up of the hardy plant borders. Bulbs are visible now, so that the work can be undertaken without injuring these. As the work goes on any lifting and replanting which have hitherto been delayed are being attended to. Plants which become too obtrusive are reduced or forked out as the case may warrant. Such subjects as the Achillea family are reduced by forking out all superfluous roots, these running almost as freely as Bishopweed. The useful *A. ptarmica* fl. pl. (The Pearl) is a confirmed offender in this respect, for not only does it find its way through and among Box edgings, but it invades the stools of other plants as well. *A. serrata* and *A. millefolia rosea* need similar attention, but they do not encroach at such a rate as the other variety mentioned. The usual plague of seedling Asters is being dealt with. Year by year large quantities of these appear, and as in almost every case they are poor they are destroyed. Mont-bretias, too, are being lifted and replanted thinly. In the front portion of the borders, where there are many of the smaller and better herbaceous plants, the fork is used; but among the most robust and taller sorts in the back rows the spade is employed. Phloxes can be divided at this time, and for these plants—as well as for strong growers generally—a good allowance of well-decayed manure must be provided. Such things as the Gypsophilas, after forking over is completed, will be covered with mounds of ashes, for slugs are very fond of the tender young shoots and soon work considerable havoc if they are not kept in check. As the work goes on care is taken that the labels are not displaced.

Late Cinerarias.—The late batch of these—all of the stellata type—is yet being kept quite cool. This batch was pricked out from the seed-pans into 8-inch pots. These were then plunged to the rims in cold frames and treated exactly as if they were planted out. The success of the experiment is undeniable, as the plants are healthy and well furnished, and will give a good account of themselves. Naturally, much care was needed in watering in their early stages, but much time was saved in potting and repotting. When the pots were lifted and cleaned it might have been anticipated that a little flagging would take place, but such was not the case.

Stove.—Throughout the present winter the display in the stove has been well maintained. Flowering plants continue to be remarkably free. Of these, the more popular include Begonia fuchsioides and B. Gloire de Lorraine and its varieties. Of the latter a considerable number of strong leaves has been put in, these leaf-cuttings rooting in a satisfactory way. Pentas carnea has been outstanding on account not only of the duration of its Bouvardia-like blooms, but for the long period over which they have been produced. Bryophyllums have given great satisfaction, B. calycinum yet being in good form. These plants incline to be of

DAYS are dull and dark now, but think of the summer with its sunshine and of your garden a perfect blaze of bloom. There is no sweeter scent than the scent of Sweet Peas—no other flowers produce such a veritable wealth of colour.

Of Sweet Peas there are no Sweet Peas to equal Eckford's. This is a fact, and recognised by expert growers in all parts of the country. Why not plant Eckford's varieties this year and make quite certain that your garden will repay your labour with the maximum amount of pleasure.

Send at once for Eckford's new finely illustrated Catalogue of all flower and vegetable seeds, which are guaranteed the most prolific of their kind.

Genuine Eckford Seeds can only be obtained direct from Wem. No agents are employed.

SPECIAL SWEET PEA COLLECTIONS FOR 1916.

<p>EXHIBITOR'S "A" COLLECTION. 40 Splendid Waved Varieties. This collection includes a half packet of each of 20 novelties. The number of seeds, other than Novelties, will be 20. This is splendid value. Price 15/-, post free for cash.</p>	<p>EXHIBITOR'S "C" COLLECTION. 24 Splendid Waved Varieties, excellent for any purpose, fine for exhibition. 12 seeds of each. Price 5/6, post free for cash.</p>	<p>EXHIBITOR'S "D" COLLECTION. 12 Splendid Waved Varieties, excellent for any purpose, fine for exhibition. 12 seeds of each. Price 2/9, post free for cash.</p>
<p>VILLA "A" COLLECTION. 50 Splendid Varieties, 25 Seeds of each, exquisite for garden effect and cutting. All fine flowering and strong. A fine range of colour. Price 10/-, post free for cash.</p>	<p>VILLA "B" COLLECTION. 24 Varieties. A splendid range of colour for garden effect and cutting. 50 seeds of each. Price 5/6, post free for cash.</p>	<p>VILLA "D" COLLECTION. 12 Varieties. The same as Villa "C" exactly, only 25 seeds of each variety. Price 1/6, post free for cash.</p>

We also send a specially written Booklet on the Culture of Sweet Peas FREE with each collection.

A VEGETABLE GARDEN for 6/6.

ECKFORD'S IDEAL COLLECTION OF VEGETABLE SEEDS. Carriage Paid for Cash.

This Special Collection of Vegetable Seeds is put up for the purpose of letting everybody test for themselves ECKFORD'S PURE & HIGH-CLASS SEEDS. The quantities are sufficient for Ordinary Gardens, Allotments, etc., and contain the following:—Four half-pints of Eckford's Pedigree Culinary Peas for succession; half pint each of Broad Beans, Dwarf French Beans, and Scarlet Runners; and liberal packets of the following small seeds: Beet, Borecole, Broccoli (three varieties—early, medium, and late), Brussels Sprouts, Early Cabbage, Pickling Cabbage, Savoy, Carrot, Early Cauliflower, Celery, Cress, Ridge, Cucumber, Lettuce (two varieties), Mustard, Onions (two varieties), Parsley, Parsnip, Radish, Spinach, Tomato, Garden Turnip, and Vegetable Marrow.

The above are all excellent kinds—fine for exhibition. If pints of Peas and Beans are required instead of half-pints, the price of the collection will be 9/- CARRIAGE PAID.

We include, Free, a specially written Booklet on Vegetable Culture for the Amateur. For places abroad the Ideal Collection will be 8/6 and 11/- respectively, post free for cash.

Will Customers kindly note that we cannot alter this Collection.

FREE Send a Post Card to-day for large Illustrated Catalogue. It gives all particulars of the NEW SWEET PEAS for 1916, and contains a full list of ALL FLOWER and VEGETABLE SEEDS necessary for your garden.

HENRY ECKFORD, F.R.H.S.,

Seed Grower and Specialist,
Dept. 64,

WEM, SHROPSHIRE.

spindly habit, and frequent pinching is necessary in the younger stages in order to induce symmetrical plants. The flowers of Bryophyllums are of no use for cutting. Bougainvillea Sanderiana is again blooming freely. Orchids, chiefly Cypripediums of good sorts, are very few, and the blooms last well. Stray pieces of Pancratiums from time to time throw up a spike, and Coleus thyrsoides lends variety in point of colour. Thunbergias and the usual run of brightly-coloured, fine-foliaged plants aid in making an attractive display. Syringing has not yet been recommenced, the necessary moisture in the atmosphere being supplied by occasional damping along the pathways. No striving after a regular and fixed heat is attempted. The conditions of the thermometer out-of-doors regulate the heat of the stove—65 degs. at night in mild weather, correspondingly less when the nights are frosty.

Greenhouses.—Plant-houses are more popular during the winter months than is the case at other times. Chrysanthemums have had a prolonged season, and there are still a few plants of the latest varieties—single and double—available. Late Chrysanthemums are invaluable in January, but they are at times capricious, and if the weather is abnormally damp they sometimes fail to expand satisfactorily. Still, they are worthy of inclusion from year to year. Salvias continue to be bright. *S. splendens*, *S. s. grandiflora*, *S. rutilans*, and *S. lactiflora* have been, as usual, a "stand-by," but *S. Bethelli*, owing to its disappointing habit of refusing to develop its flowers, will be discarded. The less regret is felt on this account, as the variety is of a stiff and ungainly habit, although, of course, none of the Salvias is exactly graceful, excepting, perhaps, *S. rutilans*. Bulbs are useful alike for cutting and for decoration, and a fresh batch of the usual subjects was introduced in the course of the week. Smaller stuff includes Cinerarias of sorts, the various Primulas, some Lorraine Begonias, Coleus thyrsoides, Heliotrope, and Zonal Pelargoniums. Year by year I am confirmed in my belief that to see Primula malacoides at its best it ought to be grown in 10-inch pans, five plants to the pan. Handsome as this variety is in 4-inch and 5-inch pots, it is much more imposing and showy when grown in pans. Arum Lilies will shortly be useful, and a roof plant of Acacia dealbata will presently be handy for cutting from. Watering must not be excessive, avoid damp by free ventilation, and keep down fire-heat as much as possible during mild weather.

Plants for spring flowering under glass.

—Those who may, under present circumstances, be keeping houses quite cool will find several of the border plants useful for indoor cultivation. *Hoteia japonica*, *Dielytra spectabilis*, and Solomon's Seal make fine pot plants. So, too, do Montbretias, and, of course, the early-flowering Gladioli—The Bride, Ackermannii, etc. The Montbretias must not be unduly hurried, succeeding better, it will be found, when given quite cool treatment. The Plantain Lilies—Funkias—are also very useful for this purpose. These, however, do not object to a considerable degree of heat. In all these cases copious supplies of moisture are necessary during the period of growth.

Orchard-house.—If any work yet remains in the way of training Peaches which are planted out, there ought not to be much further delay, for buds are visibly plumping now, and are easily rubbed off. Trees in pots must be looked over at

regular intervals in order that the needful amount of water may be given. Meantime, to keep the buds back, let there be free ventilation, except when the weather is exceptionally frosty.

Wall fruit.—A beginning was made during the week with the tying and training of Peaches and Nectarines out-of-doors. These are untied or un-nailed each season, the trees cleaned, and the wall washed with hot lime. Thin training is done, superfluous shoots being cut cleanly out. Part of the wall is wired, and on other parts nailing to the wall is resorted to. Opinions differ as to the relative value of the two methods; but, for my part, I prefer the older fashion of nailing. It seems to me that the closer the shoots are trained to the wall the cosier they are, and there is an absence of the draught which is present when the branches are trained to wires 4 inches or 6 inches away from the wall.

Vegetable garden.—Owing to the sodden state of the soil it continues to be impossible to push on the work. During the week preparations were made for the sowing of early vegetable seeds under glass, by sifting soil, leaf-mould, etc., and getting them under cover in order that they may dry a little. Sowing will claim attention early in the coming week.

W. MCGUFFOG.

Balmie Gardens, Kirkcudbright.

OBITUARY.

M. VIVIAND MOREL.

In a letter, Miss Willmott says:—"I am sorry to tell you that our dear friend Vivian Morel is dead. I have not seen him since the war broke out, but until then I never missed an opportunity of meeting him, and many were the botanical expeditions we took together. I had a great regard and appreciation for him. I always considered him one of the most original and remarkable men I ever knew. His knowledge, memory, and accuracy were of a high order. He was the best practical gardener, the best field botanist, and one of the kindest and most amiable of men. Had the wheel of fortune taken him out of his groove at Lyons his ability and literary gifts would have made him known and justly appreciated throughout the world. We were firm friends for many years, and I learned from him what has been of the greatest use to me. He was held in high esteem amongst his colleagues and greatly beloved in Lyons."

Trials at Wisley.—The director begs to call attention to the following trials to be held at Wisley in 1916:—Delphiniums (perennial): Three plants of each variety, to be sent by February 29; entry forms may be obtained on application. Mossy Saxifrages: Considerable confusion exists with regard to the naming of the Mossy Saxifrages in gardens. A collection of all the forms in cultivation is being got together to grow on in order to compare them and straighten out the nomenclature, and the director will be grateful if all who grow them will send him two plants of each variety for this purpose. They should reach Wisley by February 29; entry forms are not necessary. Sedums: The director would also be glad to receive Sedums to add to the Wisley collection for the same purpose; no entry forms are required, but plants should be sent by the end of February. Letters should be addressed to The Director, R.H.S. Gardens, Wisley, Ripley, Surrey; and goods sent via Horsley Station, L. and S. W. Railway.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly written on one side of the paper only, and addressed to the EDITOR of GARDENING, 63, Lincoln's Inn Fields, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, the name and address being added to each. As GARDENING has to be sent to press some days in advance of date, queries cannot always be replied to in the issue immediately following their receipt. We do not reply to queries by post.

Naming plants.—All who wish their plants to be rightly named should send fair examples of each—the stem, leaf, flower, or fruit. (Snippets of leaves and points of shoots are useless.) Not more than four plants should be sent in any one week by the same correspondent. Where more than one kind is sent they should be numbered. Of conifers the fruit should always be sent.

Naming fruit.—Several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. We can undertake to name only four varieties at a time.

PLANTS AND FLOWERS.

Growing Ten-week Stocks (C. R.).—Ten-week Stocks sometimes go off with a disease known locally as blackleg, which is chiefly caused by sowing early in heat, and permitting the plants to remain too long in the seed-pans. With more rational treatment, not so much forcing, sowing thinly, and pricking off as soon as they can be handled, and hardened in cold frames, there will not be much risk of failure.

Oleander with dirty leaves (F. F.).—The blackness on the Oleander leaves is caused by brown-scale. The leaves and the stem of the plant should be well and frequently sponged with soapy water to which a little Tobaccoliquor has been added. As the scale adheres closely, it may be loosened with a pointed stick. Syringe with clean soft water after sponging. If this treatment is followed up the plant should soon be clean. See that it does not get over-dry at the roots.

Cinerarias in bad condition (Anxious).—The behaviour of your Cinerarias would suggest that they have been kept too warm and close, for, though excessive stimulants act in the same way, a dose of weak manure-water once a week should not hurt them. A good light position in the greenhouse, a free circulation of air, and a maximum temperature of 55 degs. or thereabouts are very suitable to Cinerarias. We presume your plants are free of aphides or green-fly, as these pests often attack the flower stems and weaken them. The XL All Vaporiser will keep these in check.

Pelargoniums diseased (Bewildered).—The cause of your Pelargoniums being diseased as in the tiny specimen sent is undoubtedly their being kept far too warm and with an insufficient circulation of air. You say that the structure in which they are growing is kept at from 50 degs. to 60 degs. during the night, which with a corresponding rise during the day is warm enough for many stove plants. A temperature of 45 degs. by night is quite sufficient for Pelargoniums, and they should be given plenty of air whenever possible. Meanwhile, the plants may be sprayed with a rose-pink coloured solution of permanganate of potash to check the fungus which is present on the leaves.

Raising Seedlings (Anon.).—You do not state what plants the seedlings referred to consisted of, the kind of soil employed, or the temperature. It is full early yet to begin raising seedlings of many things. Zinnias, for instance, are certain to fail if started too soon. The chief points to be observed at this early season are extra free drainage and a small depth of soil only, this being of a light and thoroughly sweet and porous nature; to keep the seedlings well up near the glass after germination takes place, and to water only as required, taking care that the bottom does not get dry while the surface is moist. Perhaps there is too much steam in the frame. Do not let the temperature exceed 50 degs. to 70 degs., and prick off the seedlings as soon as possible.

Clivia miniata (J. Lowc.).—This showy plant flowers naturally in the summer, earlier or later according to the temperature and treatment afforded, or it may be forced into bloom in the spring, by placing the plants in a brisk

heat early in the year. It is a strong-rooting subject, requiring plenty of root room, and if at all pot-bound shifting into a larger pot in the spring, just as the new growth is commencing. Large old plants may be divided in the spring, but when this is done they frequently do not bloom till the following season. Liquid-manure may be given with benefit to well-rooted plants as soon as growth commences. It may be safely wintered in a cool greenhouse if kept moderately dry.

Treatment of Caladiums (C.).—It is desirable to start these at two different times, by which means a portion may be had in the autumn, with handsome foliage, at the time when the earliest started plants have lost their colour. In potting it is well to consider whether large or small examples will be the more useful, for in no case is it advisable to over-crowd the pots, as, where this occurs, the leaves will not acquire their wanted size. They will succeed in a staple of either loam or peat, but the foliage possesses more substance when grown in loam than in peat.

Treatment of Ardisias (F.).—These are most useful when comparatively small and furnished with leaves to the base. Any that are getting too large, and that have lost their lower foliage, should now soon be headed down and put into a brisk heat, where they will at once make several shoots. When these have attained a few inches in length, all but one can be taken off with a heel and struck. They will make good small plants much quicker than seedlings. The stools may then be partially shaken out, repotted, and grown on with a single stem, a way in which they look much best.

Grevillea robusta losing its leaves (M. B.).—The plant of which you send leaves is not a Fern, but the above. In some districts it is called a Fern owing to the resemblance of its leaves to Fern fronds. It is not at all unusual for the leaves of this plant to fall off, as yours have done, more especially when the plant is getting old. It requires ordinary greenhouse treatment, and in winter the temperature should never fall below 45 degs. Thorough drainage and careful watering are very important, more especially in the younger stages. In the London parks it is used as a dot plant with such plants as Tufted Pansies for a groundwork.

Rock gardening (Alpine).—We very much fear from your description that it would be well nigh impossible to advise you as to what is best to do without seeing the place. The illustration which appeared in our columns nearly four years ago, and to which you refer, is but a fragment of a very large whole with

rock associations on all sides, entirely distinct from those you describe, and with rocks often enough of several tons each, hence we feel that the two could not be compared. With the rocks in position and having particulars of the stone employed, aspect, and other essentials, a selection of plants might easily be given. It is another matter altogether to advise what to plant on non-existing rockwork. We are pleased to know you have achieved so much success from following our advice as to the dry wall.

Oleanders (O.).—To induce these plants to flower freely they should be encouraged to make a vigorous growth during the spring and early summer, by giving them one or two liberal shifts, using rich, loamy soil, and when well rooted giving plenty of water and weak liquid-manure. At the same time they should have a light position, with little or no shade, and free ventilation. Towards the autumn ripen the growth by full exposure to sun and air. During the winter keep cool and airy, and moderately but not too dry, as the foliage is evergreen.

Flowers at Christmas in the greenhouse (Enthusiast).—In a well managed greenhouse there ought to be in bloom at Christmas Chinese Primroses, single and double flowered, also Primula obconica, Persian Cyclamens, Cinerarias, Zonal Pelargoniums, Heaths (Erica) of several kinds, Epacris, Bouvardias, Abutilons, Heliotrope, late Chrysanthemums, and Salvias; also Roman and Italian Hyacinths, early Narcissi (Paper-white, N. Stella, etc.), and perhaps some pots or pans of Scillas, Snowdrops, Crocus, etc.; also Violets, Christmas Roses, Camellias, Correas, and perhaps a few Tea Roses, Cytisus, and others. With the aid of a stove or forcing-house there ought also to be Hyacinths in plenty, with Tulips, Narcissi, Azaleas, forced shrubs, Roses, Lily of the Valley, Epiphyllums, Linum (Reinwardtia) trigynum, Plumbago rosea, Arum Lilies, Poinsettias, Eucharis, Carnations, etc.

MISCELLANEOUS.

A poor lawn (Edwin Campbell).—No; the only way is to see to it that the soil is deeply dug and well manured before laying the turf or sowing the Grass seed. In dry weather the lawn must be frequently well soaked with water. Evidently your lawn is in poor condition, this accounting for the poor sward of Grass that prevails. Giving the roots good, deep soil is far more likely to keep the ground in the condition in which you want it than watering. No practicable watering will make up for a deficiency in this respect.

SHORT REPLIES.

Brentwood.—1, If the cuttings are strong and healthy you may use these with every hope of success. 2, Yes, you can prune the Roses as we advised. 3, Cut the Pelargoniums down, and dress the shoots with Gishurst Compound. 4, Clear away the soil till you find the roots of the Vines and add fresh loam with an addition of some bone-meal. You should procure a copy of "Vines and Vine Culture," which can be had from Mrs. Barron, 13, Sutton Court-road, Chiswick, London, W.; price 5s. 6d. post free.—**Constant Reader.**—The only thing you can do is to purchase retarded crowns from those who specialise in this work, and who have gone to heavy expense to do so.—**South Stafford.**—The best plant for such a position would be the Aucuba. Get the male and female forms, and then if all goes well you will have the added beauty of the fruit.—**W. H. G.**—There is no need to grow the Laburnum on the wall. If you can do so, we should remove it and plant it in the open.—**South Stafford.**—Your best plan will be to at once consult a hot-water engineer.—**Skisdon.**—In addition to the answer given you in our issue of the 25th, page 50, you should write to Miss M. Hope, the Secretary of the Woman's Herb-growing Association, 46, Queen Anne's Chambers, Westminster, London, S.W.—**Amateur.**—Seeing that you are manuring the ground, vegetables of all kinds should do well in such a soil. In the case of Peas, Runner Beans, etc., it would be necessary to mulch them well and water freely should the season be dry. All root crops, as Potatoes, Carrots, Turnips, Beet, and such like, should succeed. The great thing is to keep the hoe going in the summer, this, besides keeping down weeds, also aerating the soil, which, being loose, acts as a mulch.—**M. B.**—The only thing you can do is to cover the tree with fish-netting, which is very easily done.

NOTES OF THE WEEK.

Snowdrops in Lancashire.—Readers may be interested to know that I have had Snowdrops in flower about a fortnight.—M. CLARKE, *Grange-over-Sands*.

Early growth.—An extraordinary instance of early growth this season is *Andromeda japonica*. Many of the red flower-trusses have turned white, and a few flowers were open yesterday (January 18th). This is quite three weeks earlier than usual. Still more extraordinary are a few flowers on the Connemara Heath, both pink and white.—E. CHARLES BUXTON, *Coed Derw, Bettws-y-Coed*.

Berberis fascicularis.—Far the best flowering shrubs here now are the hedges of *Berberis fascicularis* put in four or five years ago to screen some nurseries in the woods. I suppose one gets over-stiff in one's opinions, but no *Berberis* will do for us here what this plant does, and yet you very rarely see it. I got my *B. fascicularis* from Fisher, Son, and Sibray, Sheffield, who are nearly alone in having a stock of it.—J. C. WILLIAMS, *Caerhays, Cornwall*.

A note from Bettws-y-Coed.—There were severe frosts here during November for a fortnight, the ice on ponds being at least 3 inches thick. I am, therefore, surprised to see that *Parochetus* planted at the edge of a pond and trailing into the water is uninjured. It is now covered with fresh foliage. Several goldfish which have been in this pond for a good many years were killed by the ice. There is fresh foliage on *Berberis Thunbergi* and on *Tropæolum speciosum*.—E. CHARLES BUXTON.

The white-flowered Mezereon.—This has been in flower here from about January 4th. This is early for it here, but it always blooms considerably in advance of the purple or crimson varieties. When it comes early, as this year, it is liable to have all the opened flowers destroyed by frost. Fortunately, a later display generally follows. This white variety produces wax-like, yellowish berries, from which seedlings can be easily raised if sown in the open or in pots.—S. ARNOTT, *Dumfries*.

Erica carnea præcox rubra.—One of the earliest of the new varieties of *Erica carnea* and also one of the brightest is *E. carnea præcox rubra*. It is one of the set of twelve varieties sent out by Messrs. Backhouse in 1912. It is of comparatively erect growth, and bears dainty spikes of bloom of a good rose-carmine with madder

brown tips to each. It is a gem for the Heath or rock garden, and is at present (January 13th) in almost full beauty.—S. ARNOTT.

Roses in south-west Scotland.—Having been informed that climbing Roses had suffered from the early frost this winter in the south-west of Scotland I have been making inquiries, with the result that there appear to be few places where such has happened. In my own garden some unripened growths have been killed, but the damage done is no worse than usual. Some inquiries regarding some of the other Roses have brought me the information that Comtesse du Cayla has suffered very severely in one nursery in which Roses are a speciality.—ST. CUTHBERT'S.

The Gladwin (*Iris fœtidissima*).—In mentioning various berries and late-flowering plants no one seems to have noted the Gladwin (*Iris fœtidissima*), the bright orange-scarlet fruits of which rival many of our flowers. Here in Dorset, where it grows wild in abundance, I do not know what I should do without it. I grow it in the shrubbery. I notice one reader complaining of *Petasites fragrans* flagging in water. The flowers will not flag if the vase is taken to the plant and the blossoms put into the water immediately they are cut. *Heliotropes*, *Helianthus*, *Lilacs*, and other things likely to flag I treat in the same way.—M. B.

Colchicum montanum.—This winter-flowering Meadow Saffron is in bloom at present and will remain in flower for a considerable time. It is a most useful rock garden or border species, and deserves consideration for the sake of its purplish cups of bloom. They are not so starchy in form as those of some *Colchicums*, and look well when showing through a carpet of a mossy Rockfoil. *C. montanum* is rather variable, and several forms are recognised by Baker. The one here is, I believe, what is recognised as the type, said to bloom from October to June. I grow it on rockwork and facing south-west, but where it receives little winter sunshine.—S. ARNOTT.

Wagner's Snowflake in Scotland.—*Leucojum vernum* var. *Vagneri* is now in full bloom in several parts of the garden. In most years a much larger proportion of Snowdrops is in bloom before the Snowflake appears than this season. This Snowflake is one of the most precious of flowers, and for some time I have been gradually adding to the number of bulbs

here as opportunity offered, apart from the normal increase by offsets. It is bolder, earlier, and more effective than the ordinary *L. vernum*, while its earliness is a strong point in its favour. Its habit of producing at least two flowers, with very deep green spots, on a stem is pretty constant, but in some places it will give up to four blooms. Here, sheltered by a piece of wall-garden from the west winds, and a wall from those from the east and north, it has come very early. Some blooms on plants perched on the summit of a part of the rock garden look charming above the level of the eye.—S. ARNOTT.

The Poppy Anemone in winter.—Visiting the district in which I lived for a number of years I found the Poppy Anemone (*Anemone coronaria*) in bloom on January 6th. The garden is within a stone's throw of one of the upper reaches of the Solway. Yet the fact of *A. coronaria* being in bloom was worth noting for the encouragement of those who live in mild localities and have not tried this Windflower there. Even in colder districts Poppy Anemones can often be had in bloom all winter by covering them with a frame if they are grown in a sunny place, but seaside gardens may be able to dispense with this. Carsethorn, where the garden in question is, is not one of the mildest of the Solway seaside localities. The plants were established and the soil is fairly light and well drained.—S. ARNOTT.

The Algerian Iris (*Iris unguicularis*) in the Midlands.—The first flowers of this Iris were picked the first week in December, since when it has thrown up flowers daily. The number of flowers produced by plants of this Iris during the winter is well-nigh incredible. The best results are obtained when it can be grown in a single line at the foot of a sunny south wall, when it blooms very freely. It is so particular about the amount of sun and air it gets that if planted in a square mass the outside plants only bloom. Although not a difficult plant to establish, it does not usually flower freely for some years after it has been moved. The most suitable soil is a light, sandy loam with a good quantity of mortar-rubble added. Plenty of drainage should be provided in the way of broken bricks. A sharp look-out has to be kept for slugs and earwigs, or they will spoil the blooms as fast as they appear. I find lime-water and hunting for the slugs and small snails the best remedy. In gathering the blooms of this Iris it is best to cut them in the bud state, for then there

is less risk of damaging the flowers, which are very tender. The type with its broad, upright leaves is the first to flower, and is followed closely by the white variety, whilst var. *speciosa*, with narrow leaves and larger, deeper-coloured flowers, does not usually bloom till a month or six weeks later.—F. W. GALLOP, *Lilford Hall, Oundle*.

Christmas Roses.—There are Christmas Roses and Christmas Roses. Four years ago I put in several clumps, all apparently of the same species. Some died out, others flourished and grew. The soil is unkind, hungry, harsh, wet and clammy in winter, and bone dry in summer. The bed which faces N.E. is shaded by a large Elm-tree and overhung by Walnut-trees. It was an ugly little corner, where nothing thrived. I filled it with *Magnolia stellata*, *Philadelphus microphyllus*, and Laurel, with an under-planting of Ferns, Solomon's Seal, white *Scilla*, and Christmas Roses. The Christmas Roses are now strong, healthy clumps. No manure and very little attention are given. In a garden four miles away nothing will induce them to grow.—TOCKENHAM, *Wilts*.

Vitis Coignetia and V. Thunbergi.—Mr. Markham (p. 30) says *V. Thunbergi* is "similar to *V. Coignetia*, for which it is often mistaken." Those who know the two varieties will not agree with this, which is misleading and does not do justice to *V. Thunbergi*, which is the best of all the *Vitis* family. Mr. James H. Veitch, in his book on "Hardy Ornamental Vines," refers to the two varieties thus: "*V. Thunbergi*, a native of both China and Japan, resembles *V. Coignetia* somewhat in general appearance, but differs from that species in its slightly less vigorous growth, its larger leaves, and its richer, more brilliant autumn tints. The leaves are very beautiful, a foot or more in diameter. In the autumn the hues assumed by the leaves of this species are even more brilliant than those of *V. Coignetia*." I find that *V. Thunbergi* is much more brilliantly coloured than *V. Coignetia*, which seldom colours. In many other gardens, too, it is the same. I think *V. Thunbergi* infinitely superior as regards the colour of its leaves in the autumn.—E. MOLYNEUX.

Bagging Pears.—Having had some three years' experience of paper bags (*Papier cristallé*) I was interested in the correspondence on the subject. The bags I used stood a great deal of wetting, much more than any cotton material would do, as they are oiled and slightly stiff. Out of some 200 or more only about three suffered during a severe hailstorm once. Of course, they are not fitted for tying, but I used to snip them about 1 inch down the centre of folded bag at the opening before placing the fruit in, then doubled down each side hem fashion and pinned each side close. I bought the fine long pillow-case pins from a Bedford shop at 1d. a packet. These did not rust and can be used again, and by flattening the hem and the long pin, I found no earwigs got in. I could hear of no papers of this kind from any of the large seed dealers in England, but they enabled the Pears to grow a better shape and colour, and, according to Vilmorin, the material used gives extra heat instead of interfering with it, and probably prevents sudden chills at night, and in most cases was an advantage in rainy weather. Most muslin net bags are useless then and stick so tightly to the fruit that flies, wasps, and butterflies can feed through them. The bags are quite cheap in three sizes, and are sold by ½ gross or gross for a franc or two.—A. H. C.

PLANTS AND FLOWERS.

ROSES.

THE ROSE GARDEN IN FEBRUARY.

It is wise to take advantage of any favourable weather and make good any arrears in Rose-planting, while those who intend to do a little budding will find no better time than the present to put out their stocks. Seedling Briars are planted in rows 2½ feet to 3 feet apart, 8 inches being allowed from plant to plant. The roots of the seedlings are cut back to 4 inches or 5 inches from the collar, and the tops to 2 inches or 3 inches. Make the holes for the seedlings with a good-sized dibber, and take care that the roots go straight down and are not bent or curled. After completing a row, with a hoe draw up a quantity of fine soil on either side of the plants after the manner of moulding up Potatoes. It is getting late now to plant standard Briars for budding, but if care is taken to supply the knobs with a quantity of light, gritty soil good results might follow.

It is now time to cut down all stocks budded last summer. The whole of the top of the stock is removed, the cut being made just above the Rose-eye. A good sharp knife makes a cleaner cut than can be made with the secateurs. It is usual to start with the Manetti, following on with the Briar cuttings and Grifferaie, the seedling Briars being left until last. The budded arms of standards are also trimmed back now to within a few inches of the eye. The portion of the main stem projecting above the top budded lateral is also removed to within ½ inch of the latter. These cuts should be sealed with grafting-wax or some such material, first to prevent the sap running to waste, secondly to combat the ravages of the boring-grubs, which often attack freshly-cut standards, eating their way down the pithy centre of the stem and arms. It will now be necessary to provide supports to which the young, delicate Rose growths may be tied. This is done in the case of standards by tying a split cane or light stick of any sort to the top of the stem, allowing it to project 18 inches to 2 feet above the stem. This top-stick must be very firmly secured to provide a good support for the young bud against the roughest wind. In the case of dwarfs a 2-foot stick is firmly placed in the ground about 1½ inches in front of the eye.

The Rose-beds may now be lightly forked over before the ground becomes hard. Those who wish may first give a light dressing of short manure, which should be worked under the surface during the forking up. Late in the month a start may be made with the

PRUNING, the hardier climbers and Ramblers being dealt with first. Many of the older limbs may be entirely removed with advantage, the lateral growths on the remaining shoots being cut back to three or four eyes. Do not forget the Rose hedges, which retain their freshness and vigour much longer if annually thinned out. There is usually plenty of young growths that may be used to fill up any gaps caused by removing the older limbs.

POT ROSES under glass will now need constant care. The earliest batch should soon be showing flower-buds, and these may be helped with supplies of weak liquid manure twice weekly. The plants will appreciate a good syringing on bright mornings, and a little top ventilation may also be allowed, but must be withdrawn early in the afternoon. Keep the thermometer between 55 degs. and 60 degs. by day

and avoid sudden fluctuations. On the appearance of aphid or red spider the house should be thoroughly fumigated. Mildew is best held in check by syringing the plants with a hot solution of soft soap and quassia. Sulphur dusted over the foliage through a muslin bag is also effective against this pest, but it gives the plants rather an unsightly appearance. Plants that were potted early in the autumn and are now in the cold house will probably be pushing into growth. If so, the most forward may be placed in the cooler part of the forcing-house and lightly pruned, when in about ten weeks they will bear some very nice flowers. Do not supply much water to the roots, but syringe often and well.

EGLANTINE.

Rose Roger Lamberlin.—This was introduced by Schwartz in 1890. Its pedigree can only be surmised, but it probably sported from that old favourite Prince Camille de Rohan, for not only is it similar in habit, but occasionally it produces blooms very similar to, if not identical with, those of Prince Camille de Rohan. Roger Lamberlin is a vigorous grower, sending up long, semi-pendulous shoots, the blooms being produced at the tips and also on laterals thrown out from the shoot. The buds are very firm and appear somewhat malformed, but, as they expand, the short petals arrange themselves quite symmetrically. The colour is equally unique and quite distinct from anything else in the Rose world. The base colour is like that of Prince Camille de Rohan, a dark, rich crimson-maroon, each petal distinctly edged with pure white. The blooms are still more attractive by reason of their sweet scent. As a large, freely-grown bush it is excellent, while it is also very suitable for pegging down.—EGLANTINE.

Rose Jersey Beauty.—Grown on a pillar, a trellis, a wall, or as a standard, Jersey Beauty unfailingly gives pleasure. It should receive a little more favour now that single Roses are being more sought after, though it rests its claims upon higher grounds than those of the vagaries of fashion in flowers. In bud the flowers are of a charming pale yellow, and when open show a paler shade of the same colour, passing off to cream, and made still more pleasing by the yellow stamens. It is difficult to say in what way it should be grown to show its fullest beauty, as any of the positions referred to above will show its value well.—SUB ROSA.

Rose Edgar Andrieu.—Of the new Rambler Roses introduced during the last few years, none is perhaps more worthy of notice than the Wichuraiana Edgar Andrieu. The colour is a rich blood-red, shaded crimson. The individual blooms are much larger than those of Excelsa, and the effect obtained from large trusses of these flowers can readily be imagined. Of all the existing crimson Wichuraiana Roses, this is certainly the most effective, whether grown on an arch, a pillar, or as a weeping standard.—EGLANTINE.

Ayrshire Rose Dundee Rambler.—For clambering through trees or covering high walls or trellises, pergolas, or arches the Ayrshire Roses, though only summer bloomers, should not be neglected. They are ever-green, and when not too severely pruned bloom very freely. Among the prettiest is Dundee Rambler, whose white flowers, prettily edged with pink, most people appreciate.—SCOTCH ROSE.

Hybrid Sweet Briars.—As hedges or division lines across the lawn or in any position where required, these are very useful. When flowering is over a beautiful crop of hips brightens up the place. It is well to grow a batch of Sweet Briars in pots for the sake of the sweet foliage to mix with other Roses. The common varieties may do for this work.—E. H.

Rose Juliet.—It is pleasant to note the favour which is being shown to this Rose in northern gardens. One of its many recommendations is its delightful perfume. It is also free in growth and in bloom. The reverse of the petals is a good old gold, the inside a charming carmine-crimson changing to pink.—SCOTCH ROSE.

TREES AND SHRUBS.

VIBURNUM RHYTIDOPHYLLUM.

This is one of the most remarkable of the new shrubs which have been introduced during the present century. A native of Central and Western China, Mr. E. H. Wilson sent seeds to Messrs. Veitch in 1900. The young wood and the undersides of the evergreen leaves are covered with a dense felty mass of light-brownish hairs, the upper surface of the leaves having a curiously netted or wrinkled appearance. The flower-buds are formed on the completion of growth, and sometimes a few blooms expand in autumn, but May is the correct blooming time, the flower-heads being then 6 inches to 8 inches across, the colour creamy-white. They are succeeded by a generous crop of fruit, which ripens in August, the fruits being alternately red and black. It should not

Part of a plant of *Viburnum rhytidophyllum* at Lilford Hall. May, 1915.

be exposed to cutting winds, and is benefited by a little shelter.

Mr. F. W. Gallop, The Gardens, Lilford Hall, Oundle, sends us the following regarding the plant, a part of which we figure this week:—

"This beautiful Chinese shrub is quite hardy in these gardens and does not require the shelter of a wall as many suppose. Moreover, when planted against a wall half of its beauty is lost, as its natural bush-like form requires plenty of room for development. The plant here figured is growing in a border with other shrubs, sheltered only by evergreens at the back. The soil is a medium loam containing lime. The flowers, which are nearly pure white, usually set large clusters of berries, which in August are red, turning to a dark purple when ripe."

Birds and berries.—While the majority of the Hollies were stripped of their fruits before Christmas, one particular tree is yet well laden with berries, although the birds (chiefly mistle-thrushes) were more numerous than usual. The variety is *Ilex glabra*, one of the

most prolific of the berry-bearing Hollies, and the berries appear to be distasteful to birds. On two occasions I picked up a couple of thrushes which had evidently partaken of the fruit of this particular tree. They were lying in a semi-comatose condition in its close vicinity, and the berries had apparently acted as an emetic. After a short time they recovered.—W. McG., *Balmac*.

WALNUTS.

[To the Editor of GARDENING ILLUSTRATED.]

SIR,—Your correspondent, W. J. Farmer, enquired (p. 730, December 4th, 1915) regarding Walnuts suitable for making Walnut butter, and also for the name of a bush Walnut. I have been hoping to see some information given in reply. Here in East Suffolk the Walnut appears to grow well, and there are three sizes of nuts produced in some of the gardens in Woodbridge. One is called the "soft-shelled," and is a large nut, another is of ordinary size, and a third bears small nuts not much bigger than a Cobnut or Damson Plum.

In your issue of March 16th, 1912, p. 169, you gave a detailed account of the best French varieties, extracted from an article by M. F. Lesourd in *Revue Horticole*. Of those, *Juglans regia racemosa*, called by the French a *grappes*, and grown in Indre and Vienne, might perhaps be what "W. J. F." is looking for, fertile, hardy, and bearing nuts in bunches of a dozen or more. Several were mentioned as being grown for oil, and probably the Walnut butter is a French product. In an old book, "Pomarium Britannicum," by Henry Phillips, F.H.S., 1829, it is said of the oil: "They eat it instead of butter at Berry in France." He remarks of the Walnut as an English tree that Gerard mentions it and Turner also in his "Herbal" dated 1564. He instances a tree planted in the garden of a Mrs. Maxwell, of Terraughtie (about 1810), which produced good nuts twelve years later, and he continues: "There are at this time" (say 1822) "seven Walnut-trees growing in a little meadow at Greenwich not exceeding $\frac{3}{4}$ acre of land, the fruit of which has been sold for some years past to one person at £30 per annum." The owner, he says, refused 1,000 guineas for them for the timber. This refers to the high prices paid by contractors for Walnut wood during the war, and doubtless, then, England was being denuded of Walnut-trees. He quotes Evelyn's "Sylva," showing how profitable Walnuts were in former days. They were planted by the thousand by improving landowners in Essex, Hants, Surrey, etc. He also mentions some Walnuts shown at the Horticultural Society in 1820 called "Highflyer," of a long, oval shape, very thin-shelled, with kernel full and high-flavoured. They came from a tree in a small garden of a grocer in Thetford, and he says: "They seem to have been originally confined to the neighbourhood of that place and of Bury St. Edmunds." EAST SUFFOLK.

The Monterey Pine (*Pinus insignis*).—Visitors to the south-west counties of England and Wales cannot fail to be interested in this Pine, for it is widely grown there. It is also found in other parts of the southern counties, and in some places is represented by excellent examples, but, as a rule, it is not seen to so great advantage as in Devonshire and Cornwall, except in favoured situations near the coast. In a state of Nature it only occurs over a small area in Monterey, California, having for a companion *Cupressus macrocarpa*. The cones are distinct and, as a rule, remain on the branches for many years, the scales remaining closed and the seeds perfectly fresh. On vigorous shoots whorls of several cones are produced, but elsewhere they may be borne singly. When planted under suitable conditions growth in height and trunk diameter is very rapid, trees adding to their height from 2½ feet to 3 feet each year for many years in succession. Although tender when grown inland it is quite hardy in the places named, and stands considerable exposure to winds from the sea; in fact, it can be planted to give shelter to more exacting subjects. It must be planted permanently whilst quite small. The species is sometimes called *P. radiata*, and has been grown here since 1833, when it was introduced by David Douglas.—D.

New Index and Binding Cases for completed Volume.—The Index to Volume XXXVII. of GARDENING ILLUSTRATED is now ready (price 3d., post free 3d.). The Binding Case for the same volume is also available (price 1s. 6d., by post 1s. 9d.). The Index and Binding Case can be obtained from any newsagent, or from the Publisher, 63, Lincoln's Inn Fields, London, W.C. If ordered together, the price of the Index and Binding Case is 2s., post free.

A man who owns a small holding had a fine old tree which he wanted removed, but no one would give him enough for the log to pay for cutting it down (some 10s. or 12s.). I bought the log eventually and have had some furniture made out of it after three years' seasoning. If I enquire for English Walnut from the cabinet-makers the price is high, so one can only suppose that it should be worth planting even for timber. In former days it was considered highly profitable to plant Walnuts in England, but perhaps nowadays a little sum in arithmetic would show that the foreigner can do it more cheaply.

The old idea was that if the taproot be cut when the seedling tree is young the tree will break into branches near the ground. Is that possibly the sort of bush-tree that "W. J. F." has heard of? But if the nut be sown where it is to grow, and never transplanted, it will form a tall stem and make a large tree. Walnuts grow from nuts as freely as Oaks from acorns, so anyone can try.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

THE ALPINE-HOUSE.

THERE is a deal of truth in what "Kirk" (page 1) says of the alpine-house, but it is a question as to which there are two sides. I think that "Kirk" is rather unfortunate in his choice of plants to enforce his view that the "increased use of the alpine-house is to be deprecated." There are many parts of the country where *Iris reticulata* has but a short time of beauty in the open unless protected in some way, especially in an early season. Of course, this shelter may be afforded by using a bell-glass or hand-light, but even that appears artificial in the case of a hardy bulb such as this. Then many of the earliest flowers are soon rendered useless by even a short spell of bad weather, without taking into account the stormy times which often prevail for weeks at a stretch. One might mention such things as *Saxifraga Burseriana major*, *S. apiculata*, *Synthiris reniformis*, and a number of other plants whose beauty is prolonged when grown and flowered under glass during the earliest months of the year. For such Irises as *Histrio*, *histrioides*, *Bakeriana*, and *Rosenbachiana* it is a great boon to be able to shelter them during their flowering season. In certain seasons, also, it is almost hopeless in many places to attempt the winter-flowering *Crocus* species, such as *C. hyemalis* or *C. vitellinus*. When we come to consider the later flowers the opinion of "Kirk" will have greater support. None of our alpine look so well in a pot and under glass as in the open, and there is little need to shelter these in the alpine-house when they normally come into bloom in April or May. Even March is not so unkindly in most seasons. An alpine never looks so well as among as natural surroundings as can be had in a garden, and the later flowering plants, as a rule, never show their true character when cultivated under glass. Is it worth while to devote a house to alpinics for the sake of, say, a couple of months? I do not think that it is, unless it can be utilised later for growing other things. Growing alpinics under glass increases the work in the average garden very considerably. In these times of shortage of labour and economy in other directions it is very probable that the alpine-house will not make much headway.

Δ LOVER OF ALPINES.

NOTES AND REPLIES.

Saxifraga apiculata.—With its Primrose-coloured little flowers on a carpet of green, *Saxifraga apiculata* is again in bloom. It is many years since I first made its acquaintance under the name of *S. Frederici-Augusti*. In those days it was more prized than now, as it was the earliest and best of the yellow-flowered Saxifrages then in commerce, but it is still worthy of consideration. It has anticipated *S. L. C. Godseff*, another yellow-flowered Rockfoil which is usually very early, and looks charming nestling close to the grey chips in which it is placed and showing its close carpet of green well spangled with pale yellow flowers.—S. ARNOTT.

Saxifraga Burseriana major.—This still remains one of the earliest Saxifrages, and has been in full bloom since the middle of January this year in a moraine facing almost due south, but with no protection of any kind. This moraine, composed of chips with an admixture of old mortar rubbish, suits *S. Burseriana major* splendidly. This is one of the most valuable of the *Burseriana* varieties.—S. ARNOTT.

OUTDOOR PLANTS.

EARLY SPRING FLOWERS.

THE garden that is without a Forget-me-not is certainly wanting in one of the greatest charms that the spring sunshine brings with it. We have quite a number of beautiful varieties very much superior to the old kind. That lovely kind

Myosotis dissitiflora, which had such a warm welcome when it made its appearance in English gardens, never in the true sense of the word became popular. No plant can become so unless it can be easily increased. Really popular things are required by the thousand. There is also the liability to injury from spring frosts, which not infrequently destroy its beauty just when it has become effective. Unlike the Forget-me-nots in common use, and which are weed-like as regards their reproductive powers, this species produces seed so sparingly that raising a large stock is not a very easy matter. Many who wished to employ this Forget-me-not largely had to resort to propagation by means of cuttings, which, of course, is comparatively a slow process. The easiest way I found was to grow a few plants on a north border and surface the soil with leaf-soil. In this way a certain number of self-sown seedlings were obtained without trouble, and by watering in dry weather, young growths came up from the base which, taken off with a heel, made roots freely and formed nice plants. This species must be regarded as the aristocrat of the family, endowed with a finer constitution, and must be treated accordingly. Putting it in the open, where it may catch cold winds and early frosts, is not the way to realise its beauty. It should be in intimate association with a superior vegetation, such as deciduous trees and shrubs, which give the necessary protection.

OMPHALODES VERNA, which has been termed the creeping Forget-me-not, is a good companion plant and flowers very early in sheltered positions, the first blooms opening in February. It extends freely by means of creeping rhizomes, and is a true perennial, quickly covering a square yard of ground, but the soil must be free, as in close, heavy ground it has a miserable appearance. Put it at the foot of an evergreen hedge south or west aspect, or in a cosy corner among shrubs, and you will be gratified with its pretty little blossoms when the Snowdrops open. I have never grown these in close companionship, but they should make a pleasing picture. The *Omphalodes* as a carpet with Snowdrops coming up through ought to be a success.

WINTER ACONITE, the Snowdrop, and the Snow Glory so intimately connect winter with spring that one hardly knows to what season they properly belong. In sheltered positions the Aconite sometimes opens at Christmas, but this year it is much later. Do any of your readers grow the Aconite in the Grass? It is charming there, and the foliage dies off early, so that mowing is but little retarded.

Snowdrops may sometimes be gathered in January. What precious little bulbous flowers these are, giving us an interest in our gardens when the days are short and leaden skies prevail, and at such a trifling cost, and, once established, a joy for years without renewal or removal.

ANEMONE BLANDA and *Cyclamen Coum* also belong to that limited number of hardy flowers that bridge the winter with the spring. They are now (January 20th) expanding their first blossoms, and the last will appear when the full spring flower season arrives. *Saxifraga apiculata*, *S. Burseriana*, and *S. marginata* are in the

same category, and in their wake come those little Daffodils *N. minimus* and *N. nanus*. *N. minimus* is a dainty little thing, very desirable but, unfortunately, rather capricious, only succeeding in warm, well-drained soils. BYELEET.

AMONG THE HARDY FLOWERS.

SOME DESIRABLE PLANTS TO RAISE FROM SEEDS.—I find that the *Delphiniums* come very well from seeds, and that a good strain gives a considerable variety of colour. These seedlings may not be quite up to the standard aimed at by the expert, but there will be a number of really excellent varieties. These Larkspurs will flower the second year, even if only sown in the open air in May. *Pyrethrums* come easily from seeds. I like the single varieties, but from a packet of seeds said to be saved from single varieties I had a good proportion of double flowers. *Potentillas* are easily raised. It is also well worth while to buy a packet of seeds of mixed *Lupins*, which come very well from seeds, and we can have a good variety. I have not found the perennial *Phloxes* so easily raised from seeds, as they do not seem to germinate so satisfactorily. Some dealers offer packets of mixed seeds of *Saxifrages*, but I anticipate that a good deal of trouble might be involved in getting the resulting plants named. With varieties one need not mind so much, but I think that species or forms of these should be known to us by name.

CLEMATIS DAVIDIANA.—I am told that this *Clematis* should be called *C. heracleifolia* var. *Davidiana*, but we may shorten it to *C. Davidiana*, or, to use an English name, David's *Clematis*. It is quite a nice herbaceous plant, but I would like to learn the experience of others as to its liability to disease. It does not suffer from disease with me, but some correspondents tell me that it will not grow well with them. I like its growth and its blue, fragrant flowers. Few amateurs seem to know these non-climbing *Clematisses*, but they deserve to be much more largely grown.

DRYAS DRUMMONDI.—In a catalogue I had some two or three years ago I read of *Drummond's Mountain Avens*, and was tempted to purchase a plant on the faith of the statement that it has "showy yellow flowers." Judge of my disappointment when I found that these "showy" flowers never opened fully. *Dryas octopetala* has nice white flowers, and I pictured a similar plant, the white flowers replaced by equally fine yellow ones. I have come to the conclusion that *Drummond's Mountain Avens* must be put on the fire-heap. If anybody has any knowledge of how to induce *Dryas Drummondii* to open its flowers fully I shall be under a debt of gratitude if the information is made public through these pages.

CYCLAMEN COUM.—This is just showing its crimson petals through the enveloping perianths. I always feel cheered by the sight of this and other early flowers. I find that it thrives equally well in a sunny place as in a shady one. I bought a corm and planted it in loam, leaf-soil, a little sand, and a small proportion of old broken mortar, and with the crown about an inch deep. This was according to the directions I had given me, and the "one ewe lamb" has proved successful.

AN AMATEUR OF HARDY FLOWERS.

NOTES AND REPLIES.

Gladiolus The Bride.—Although October is, perhaps, the best time for planting *The Bride* and other early-flowering *Gladioli*, corms may yet be planted. For pots a good compost is one of turfy loam, a little leaf-mould, and some sand, made rather

moist, but not so wet as to cling when pressed in the hand. A 6-inch pot may contain seven corms, and they should be planted about an inch deep and the pots plunged in Cocoanut fibre or ashes out of doors. If indoors they can be put under the stage of the greenhouse, but not near the pipes. If early bloom is needed the pots can be put into a temperature of 50 degs. to 55 degs. If planted in the open at this season they may be put 4 inches deep with a little sand about the corms.—S. ARNOTT.

Hyacinthus azureus.—I have a very early form of *Hyacinthus azureus* (syn. *Muscari azureum*) called by some H. a. lineatus, but why I do not know. It generally flowers early in February, though, as this year, I have had it sooner. To-day (January 25th) I have found a few of the spikes with open flowers. The spikes are now only a couple of inches or so above the ground, but they will soon extend, and before the flowers are all open

Flowering shoots of Freesia Chapmani.

will be from 4 inches to 6 inches high. I used to grow it facing south-west and partially sheltered by an upright-growing *Helianthemum*, but some alterations led to its removal, and now *H. azureus* is on a ledge on low rockwork and facing almost due south. It is growing in sandy loam.—DUMFRIES.

Hardy flower borders.—Further progress was made with the necessary forking and digging of these borders. Bulbs grow increasingly prominent with the advancing year, so that danger from fork or spade is minimised. Tulips, Narcissi, Squills, Hyacinths—in fact, bulbs generally—are coming away very strongly and regularly, while Anemones are already in leaf. *Dielytra spectabilis* begins to be prominent. This can be hurried on by the use of hand-lights, but as there are apt to be late frosts it is, perhaps, just as well to permit the clumps to come away naturally, except in very sheltered situations. Lifting, dividing, and replanting are being done where necessary as the work proceeds.

INDOOR PLANTS.

FREESIA CHAPMANI.

This is the result of the inter-crossing of the somewhat weak-growing *Freesia aurea*, whose blossoms are of a rich golden hue, but absolutely scentless, and the well-known and popular *Freesia refracta alba*, the flowers of which possess a delicious fragrance, followed by fertilising the blooms of the latter with the pollen of the seedlings resulting from the first cross. The hybrid (*Chapmani*) partakes of the characters of both parents, the growth and size of the flowers being suggestive of those of *F. refracta alba*, while in colour it shows a decided affinity to *F. aurea*. The blossoms of *F. Chapmani* are in colour soft yellow, with a golden sheen, and blotched inside with rich bright orange. They have a little of the perfume of *F. refracta alba*, but this feature is not at all pronounced. This first flowered in

carefully from the seed-pot, so as scarcely to disturb the rest, and prick off into 2½-inch pots in which the soil has a convex surface. Follow this process as plants are ready until all the seedlings have been transferred. When potting on allow the leaves to rest on the soil, but avoid covering the hearts. An early batch of tubers may now be started. I prefer using shallow boxes filled loosely with half-decayed leaves and plenty of sand. Place about two-thirds of the bulb in the compost and start in a temperature of 60 degs. to 65 degs.—F. W. GALLOP.

STOVE AND GREENHOUSE PLANTS CERTIFICATED IN 1915.

As with trees and shrubs, no stove and greenhouse plant received a first-class certificate during the year 1915, and the Awards of Merit were but few. Excluding Carnations and Chrysanthemums, which are dealt with by specialists, the following only were honoured:—

ABUTILON TRIUMPH.—A variety with very large pink blossoms of a semi-double character. The pedicels are stiff and the flowers have not the pendulous habit common to most of the garden varieties of *Abutilon*. This variety was sent out by M. Lemoine, of Nancy, about ten years ago. September 28th.

AURICULA EDENSIDE.—A very pretty Auricula from the well-known Douglas collection. The foliage is mealy, the flowers pale heliotrope suffused with lilac. White centre. April 13th.

BEGONIA FIREFLAME.—This is a very desirable variety of the *socotrana* hybrids of *Begonia*. The colour is orange with a rosy suffusion, and the habit of the plant good. It will no doubt become popular. November 9th.

BEGONIA LORD METHUEN.—A member of the tuberous-rooted section, the flowers being large, double, finely-shaped, and of an intense scarlet colour. July 6th.

BEGONIA MRS. W. CUTHBERTSON.—Another tuberous-rooted variety, whose flowers are of a soft clear pink. July 6th.

HYDRANGEA RADIANT.—One of the many seedling *Hydrangeas* distributed by M. Lemoine, of Nancy, within recent years. In this variety the flowers are of a clear rich pink colour. April 27th.

NERINE ROSEBUD.—A very pretty *Nerine*, whose rich pink flowers shade off towards a light-coloured centre. September 28th.

NERINE VIVID.—Of a vivid scarlet tint. A fine bold truss. September 28th.

PELARGONIUM KATHLEEN BUNYARD.—A member of the Ivy-leaved section, with richly-coloured flowers borne in great profusion. It is of considerable promise as a market variety. July 20th.

PRIMULA ADONIS.—A hybrid showing traces of *Primula viscosa*. It is somewhat suggestive of a large, bold-flowered alpine *Auricula*; colour, bright mauve. April 27th.

PRIMULA MALACOIDES ROSE QUEEN.—This strong-growing variety of the popular *Primula malacoides* has flowers of a particularly pleasing shade of rose pink. It is full of promise for greenhouse decoration. February 16th.

SENECIO MULTIBRACTEATUS, CLARE LODGE VARIETY.—A *Cineraria*-like plant with yellow disc and rosy-mauve coloured ray florets. It promises to be a useful greenhouse plant. May 18th.

SOLANUM ACULEATISSIMUM.—This is the *Solanum* which attracted a good deal of attention at one of the meetings of the Royal Horticultural Society about a year ago under the name of *Solanum ciliatum*. The Kew authorities have, however, determined that the correct name is as above. It is of a somewhat straggling habit with spiny shoots. The comparatively large,

1906 and was given an Award of Merit by the Floral Committee of the Royal Horticultural Society in 1907.

Gloxinias can be flowered in the most satisfactory manner within six months of the date of sowing the seed. By successive sowings and judicious management it is possible to have *Gloxinias* in bloom almost the year through. The most important months for sowing seed are January, February, and March. The most suitable receptacles are 5½-inch or 6-inch pots, which must be thoroughly cleaned and nearly half-filled with clean crocks, as free drainage is essential to success. Fill the pots to within ½ inch of the top with a light, porous compost consisting of fibrous loam, peat, and coarse sand. Sow thinly and evenly, slightly covering the seed with very fine soil. Place the pots in a warm, moist position, carefully shading from the sun. A light sprinkling of water daily will be necessary. Immediately any plants are large enough for shifting lift them

rich, scarlet-coloured fruits are borne in great profusion. November 9th.

VERBENA CHAMÆDRYOIDES.—An old species of Verbena with intense scarlet flowers. It would, however, appear to have been lost to cultivation till reintroduced within recent years. It has proved to be hardy in many districts, but even where such is not the case it can be readily wintered in the greenhouse and planted out during the summer. July 6th.

NOTES AND REPLIES.

Perpetual-flowering Carnations.—Cuttings that were inserted in boxes during the first week in January will now be rooted, and may be removed to a light house where a little air can be admitted, so that they may be hardened a little before potting off singly into small pots. Where space is limited it is a mistake to grow too many varieties. Better select eight or ten choice sorts which are known to do well in the particular district. Enchantress, White Enchantress, White Wonder, Empire Day, May Day, Lucy, Mikado, Triumph, and Beacon are sorts that do well with me. The shoots of flowering plants should be tied neatly and the surface soil stirred lightly with a pointed stick. It is not advisable to feed the plants with fertilisers until February, when Clay's fertiliser and soot mixed in equal quantities may be applied once a fortnight at the rate of a dessertspoonful to each plant.—F. W. GALLOP.

Cyclamens.—Complaints are by no means infrequent that the flowers do not develop as they should. More than one cause may be answerable for this, but especially the following three. In the first place an insidious mite, similar to, if not the same, as that which attacks the winter-flowering Begonias, will cause the leaves to thicken and the flowers to become deformed. This needs to be carefully watched for, and at the least sign vaporising or dipping in a solution of nicotine should be carried out. Thrips, again, disfigure the leaves and cripple the blossoms, but vaporising will keep these in check. The flower-stems, too, sometimes damp off almost as soon as they are pushed out from the corn. This may be caused by too moist an atmosphere, by an excess of stimulants, or very frequently by want of care in watering. If the water is dashed into the crown of the plant decay is almost sure to set in, as the moisture collects at the base of the stems and many of them rot off. Watering needs, especially at this season, to be carefully done.—T.

Asparagus Sprengeri.—This variety of Asparagus, when well grown, rivals the Smilax for dinner-table decoration, as the trails can be used either for laying on the cloth, the entwining of candelabra, etc., with equal effect. Old plants in baskets usually produce a good lot of seed in autumn, which, if taken care of and sown now, germinates readily in warmth. For the first season the young plants are very serviceable for room decoration and similar purposes. To obtain long trails, basket culture must be resorted to. Growths can then be had 2 yards in length if the plants are given plenty of heat and moisture. Seed can also be purchased, but it does not, as a rule, germinate so readily as that which has been home saved.—G. P.

Clivia miniata.—Disappointment is sometimes expressed at the pale tint of the blooms. This is merely a matter of position, for it will be found that the paleness is due to lack of exposure to the light. If the plants are placed where they get the benefit of any sunshine in the early part of the year the colour of the blooms will be satisfactory. *C. miniata* will remain in robust health for many years without repotting, but stimulants of some kind must be regularly given during the period of growth and blooming.—KIRK.

Asparagus plumosus.—The cut sprays of this plant are highly valued for a variety of purposes, and now is the time to increase the stock—of which it is seldom there is an overabundance—by sowing seed and raising it in heat.

GARDEN FOOD.

VEGETABLES OVER-BOILED.

THE importance of garden food is growing every year, and next to good cultivation the most essential thing is the intelligent cookery of such food. One of the mistakes commonly made is over-boiling tender green vegetables. In that way they lose their crispness and true flavour, and also the natural salts which make them wholesome. The Cauliflower over-boiled becomes so much pap and is useless as food. Experiments which have been made with animals show that over-boiling lessens digestibility. Those experiments were not made with man, but we know enough to be able to state that over-boiled food is productive of certain unpleasant effects.

Our country is richer in the Brassica tribe than any other perhaps. In the right season there are some of these that are very pleasant and wholesome food, as some of the Kales that bud in the spring, unless by over-boiling we lessen their value or cause them to lose their shape or flavour. Pouring melted-butter or sauces over such things is a mistake, as in the case of Seakale and sometimes Brussels Sprouts. If sauces are required with such things a little fresh butter or gravy is usually at hand. Even vegetables like Spinach, which are reduced to a finely-cut state, may be spoiled by over-boiling. On the other hand, dried pulse and cereals, being hard, want a considerable amount of cooking to make them digestible. The vast mass of vegetable food which is grouped under the head of pulse suffers very much from under-cooking.

COOKING CELERIAC.

(REPLY TO "GARDENING COOK.")

The blackening or discolouring of this when boiled is due to lack of care in the cooking. The Celeriac should be fresh, peeled quickly, and immediately plunged into salted water, while the remainder of the roots is being prepared. Cut into quarters and place into boiling water. Take up immediately the vegetable is tender, drain, and cover with the sauce with which it is served. If eaten plain it is as well to add a liberal allowance of milk to the water in which it is boiled, as this helps to keep the roots of a nice colour. Celeriac is, however, nicest when made into stews or other dishes, much in the same way as Celery is cooked. A nice white stew is made by cutting the Celeriac into slices, about $\frac{1}{2}$ inch thick, and boiling them for ten minutes in salted water. Drain away the water and cover with equal quantities of fresh milk and a thin white stock, and simmer until the slices are tender, but not broken. Melt a dessertspoonful of butter in a clean pan and sprinkle in a dessertspoonful of flour and fry for three minutes, taking care not to allow the butter and flour to brown. Add some of the liquid in which the Celeriac has been boiled and simmer, stirring the whole time until the sauce is smooth and cooked. Pour in the rest of the liquid, stir well, and add the slices of celeriac and simmer for a quarter of an hour longer.

A delicious supper-dish is made by boiling the Celeriac as in the previous recipe, and then chopping it rather coarsely. Flavour lightly and return to the pan with a dessertspoonful of butter. Toss in the pan until the vegetable is coated with the butter and very hot. Butter a deep pie-dish and place a thick layer of bread-crumbs at the bottom. Sprinkle a little Onion juice over and pour in the Celeriac, and cover with a thin layer of grated

cheese. Two tablespoonfuls will be sufficient. Fill up the rest of the pie-dish with a layer of bread-crumbs and pour in at the side a large cupful of the liquid in which the Celeriac was boiled. Sprinkle a little dissolved butter on top and bake in a moderate oven until the top is coloured a rich brown. Send to table in the dish in which it was baked.

To make a brown stew of Celeriac take a tablespoonful of butter and melt in a clean stewpan, add a tablespoonful of chopped Onion, and fry until nicely browned. Sprinkle in a tablespoonful of flour and continue frying for five minutes, but do not allow the contents of the pan to burn. Meanwhile slice the Celeriac and boil in a good stock until tender. Add a little boiling stock to the contents of the stewpan and simmer, stirring the whole time until the fried flour, butter, and Onions are smoothly blended with the stock, add the cooked Celeriac, and sufficient of the liquid in which it has been boiled to make the gravy of the right thickness. Season very lightly or not at all, according to taste, and cook for fifteen minutes longer. Send to table very hot.

H. THOBURN CLARKE.

—IN GARDENING ILLUSTRATED, January 1 (page 6), a question is asked as to keeping this vegetable of a good colour in the cooking. I have found that some roots, no matter how well cooked, go a bad colour. That is not the fault of the cooking but the culture, as I have found that roots that have been lifted above the soil are inclined to a bad colour when cooked. One often sees these roots exposed for sale in a shrivelled and soft condition. Such roots would not cook well, hence the importance of well covering the roots with soil or fine ashes when placed in the store, which should be only just frost proof; indeed, a few degrees would do no harm if the roots were well covered. In August or September I always draw the soil from between the rows well into the foliage to prevent discolouration when being cooked later on. To cook Celeriac, peel and quarter or halve the roots according to size, and plunge into boiling water with a liberal quantity of salt. Boil hard till quite tender, using plenty of water. I do not like the large German varieties, the smaller Paris Ameliore being better. The small Erfurt is of fine quality when cooked. C. F.

NOTES AND REPLIES.

Seakale and its use.—This is a product of our British gardens, and rarely in use in Continental Europe, a further reason, if needed, for making good and frequent use of it. It is often over-cooked and messed over with melted butter. The best way is to serve it simply, and not over-boiled, as that deprives us of the wholesome salts or potash, or whatever it may be called, of the fresh shoots. If anything in the way of sauce is desired to go with the Kale fresh butter or gravy may be used. The wild plant on our coasts is well worth looking after for those who are near the sea; the rising shoots are quite good unblanched. Some growths unblanched might well be kept for those who like it as it starts. It used to be eaten wild before the plant was cultivated in gardens.—W.

Carrots young and tender.—Carrots seem to be getting worse, if anything, in our English gardens. Is it owing to the *Daily Mail* 4-foot scale? I wish some of your learned readers would tell us how to grow in our gardens the little Carrots as grown for the Paris markets. My cook tells me she cannot get on with our Carrots. Certainly some soils are so stiff that Carrots will not do in them, but for the small supply wanted for the cook would it not be almost worth while to grow them in frames?—J. S.

FRUIT.

CONCERNING APPLES.

NEARLY twenty years ago now I could plainly see that several of our Apple-trees were giving out. The majority of these, I should add, were obtained about 1850 from a Mr. Ronalds, who then had a nursery at Brentford. So they had served a good time, and since I have been at Gunnersbury, even, they have borne good crops. Of these old trees that now remain the best are Blenheim Orange, Waltham Abbey Seedling, Wellington, Alfriston, and King of the Pippins. These rarely ever fail to give us a good return, last year very specially so. But these, even, are feeling the effects of age.

Foreseeing what was likely to happen in

colour. Later on I hope to use these for dessert.

I laid this orchard down on Grass and have up to the present time kept to the plan. I would now, however, do away with the Grass, but it is a question of labour. The soil is good loam, somewhat firm of texture—a lasting soil. It is, however, rather shallow, on an average not more than 18 inches before one touches the gravel which overlies the London clay in this spot. I had the holes well prepared, using a little well-rotted manure because of the shallow soil. I find I have to water the trees in a dry season so that they finish their crops well. I have helped the trees, however, with a mulch, and from time to time have extended the circle around the trees, which is kept free from Grass. The branches, as they extend, and

Keswick Codlin in this respect was second last season, and Ribston Pippin third. Bismarck has quite pale-coloured flowers, but they are none the less beautiful. I have for a long time thought that we might plant standard Apples in our shrubberies for pictorial effect.

JAS. HUDSON.

Gunnersbury House Gardens.

MISTAKES IN PRUNING GOOSE-BERRIES.

THE cultivation of Gooseberries has been much improved in recent years. It may, therefore, not be out of place to suggest at this season that in the different forms in which the fruit is grown it often happens that much remains to be desired in the pruning. As

CORDONS, some varieties are much more

Apple Newton Wonder in bloom, with Lane's Prince Albert showing on the left. From a photograph in the gardens at Gunnersbury House.

course of time I made another orchard close by. This would be nearly twenty years back now. For this purpose I selected dwarf trees on the Paradise stock. Most of these trees have done well and have borne heavy crops nearly every year. The best of these have proved to be Newton Wonder, Lane's Prince Albert, Gascoyne's Scarlet, Ribston Pippin, Bismarck, Cox's Orange Pippin, Pond's Seedling, Domino, Lord Grosvenor, Bramley's, Allington, American Mother, Mabbot's Pearmain, Rivers' Codlin, and St. Edmund's Pippin. Baumann's Red Reinette I found not satisfactory, so I replaced the trees of this with Royal Late Cooking, which has done well. Of Annie Elizabeth I have only one tree. It had a fine crop this past season, really handsome fruits that are still quite firm and of excellent

where not wanted to fill up the trees, are spur-pruned. Thus the trees are rigid and not influenced to any extent by the wind when carrying heavy crops of fruit.

The tallest of these trees measure about 11 feet and have a spread of 10½ feet. I planted at 12 feet apart each way, but if I were planting again I should allow somewhat more space each way for convenience both for gathering the fruits and for pruning. This pruning, I might say, is all winter pruning; I never touch the growth in the growing season. These trees began to bear when quite young, and I have had good crops nearly every year since. The most remarkable for consistent cropping of those I have named is Bismarck. To me this is rather singular, because I have noted for some years past that this variety is always the first to open its flowers.

suitable than others, and this should be taken into consideration when planting. Those of very pendulous habit, or inclined to be more than ordinarily long-jointed, are hardly acceptable. Given varieties of kindly habit it should be remembered that once the tree is formed the after-cultivation will practically be entirely on the spur system, and care should be taken that these spurs are not allowed to stand out too far from the main stem, throwing a lot more wood than is required. After the trees have been established a few years it is just as well to remove a few spurs annually, selecting a strong back break, and so building up another lot of spurs well into the stem. In the matter of

BUSHES, I think in many gardens they are far too thick, occupy too much ground in proportion to the result obtained, the

fruit is of poor quality, and they are difficult to cover if it is necessary to protect the buds and fruits from birds. Given nicely-balanced bushes to start with, they can be kept well within bounds by judicious pruning, and sufficiently thinned out to admit light and air and allow for easy picking. One feels inclined to adopt drastic measures at the sight of huge bushes with big, gnarled, Moss-covered branches. It seems hardly recognised what an excellent hedge on a small scale, practically impervious to animals, can be made with Gooseberries. Finding the hedge round part of my small garden had been much neglected and getting bare at the bottom, and hardly caring to wait for growth that would follow heading back, I decided to keep it closely trimmed and plant Gooseberries inside. Strong-growing kinds, with shoots well equipped with thorns, were chosen. A few slight iron rods were inserted at intervals along the line and the shoots loosely tied in to lay the foundation for the hedge, taking care that some shoots were nearly close to the ground. The hedge is now a bit over 3 feet high, and, as noted, sufficiently thick to prevent the ingress of small animals, besides supplying plenty of fruit. I have noted above as to keeping bushes within reasonable bounds, and this is very necessary in this neighbourhood, where the number of bullfinches renders bud protection essential if good crops are looked for.

Hardwick.

E. B. S.

NEWLY-PLANTED VINES.

AMATEURS, who have not previously had any experience in the cultivation of Vines, generally wish to give their young ones plenty of heat right from the time that the Vines are planted. Instead of applying strong heat to the Vines in the latter part of winter and through the spring it would be much better to do without artificial heat altogether, provided frost is excluded. Unduly forcing young Vines that are intended to be permanent has the same result as follows overworking a young colt. Very careful treatment for a period of at least two years is needed. When young Vines are received from the nursery the canes measure from 5 feet to 8 feet in length as a rule. Amateurs hesitate to cut them back to within 1 foot of their base, or even to shorten them by two-thirds their length. Severe cutting back is, however, essential, and the cut ends must be immediately painted with styptic or ordinary painters' knotting to stop bleeding when the sap rises freely. If, however, the sap has begun to flow, such painting will be useless. The best plan is to arch the young rod, tying the point to the bottom part. The first buds to burst into growth will be the end ones, and, when they have attained a length of nearly 1 inch, rub them out; do not cut them. Continue to so remove the young growths until the desired point is reached, then allow the shoot to grow, and duly tie it in position. If, the first year, one leading shoot and two side shoots are retained, they will be sufficient. The side shoots should be stopped when they are about 30 inches long and all sub-laterals stopped beyond the first leaf. The leading shoot should be stopped when it has grown 5 feet long, but another leader in continuation may be allowed to grow. The stopping will result in the plumping up of the buds on the lower part of this young leader. Stop all sub-laterals on it beyond the first leaf also. Always maintain the soil in a medium state of moisture; mulch with manure and ventilate judiciously; freely after the end of May. BOURNE VALE.

NOTES AND REPLIES.

American blight on Apple-trees.—This is becoming a terrible pest. It is finding its way into the amateur's garden, and it will soon be difficult to find a garden free from it. Fruit-tree nurseries are not in all cases absolutely free from it. The question now is what are the best means to get rid of it. It certainly must be tackled in a determined manner, as half measures will not do. From what has come under my own observation, a solution of Gishurst compound thickened by adding lime and soot to the consistency of paint and then applying with a brush, rubbing it in well among the spurs will be useful, but not in all cases effectual. Some will be sure to escape, and will have to be dealt with during the summer with a small brush and a liquid insecticide or one of those spraying instruments so common now for labour saving. The tar mixture which has been so useful for killing mealy-bug on Vines will be found equally good for the destruction of this blight on Apple and other trees in the garden or orchard. Of course, the tar mixture should only be used in the winter when the buds are dormant, and it will be best to avoid the buds as much as possible when using it, and to dilute the tar with hot water in equal quantities. The clay must be dried, broken up, and well blended.—E. H.

Raspberry November Abundance.

—Though of late years we have had some introductions from the Continent, so far I have seen none superior to the above. Some of the new autumn-fruiterers are none too strong, but this is excellent in this respect if given good land and ample room. No matter what the variety, there must be ample room, as at the time the fruits ripen there must be plenty of space for the sun and light to get to the plants. The above variety, for an autumn fruit, is of excellent quality. To get the best results the plants must not remain too long in one place. Far better plant new, strong canes every third year. If this is done there will be a full supply, and later than most kinds. The fruits are borne freely in clusters and of large size when well grown. The well-known Superlative was one of its parents, and the newer variety crops as freely.—F. K.

The Worcester Damson or Damascene.

—In many parts of the country, especially where the Pershore or Large Yellow Egg Plum does so well, the Worcester Damson, or Damascene as it is frequently called, is a great success. In the Evesham district the above variety is a great favourite and an enormous cropper. Most of the trees are obtained from suckers, and this is a great gain to the small growers, who plant it largely in their garden hedges—indeed, in very unlikely places, as regards the well-doing of the trees. It is remarkable how well the trees succeed, soon coming into bearing, and giving very heavy crops. The fruits are of medium size, quite black, and somewhat acid till quite ripe. It makes a splendid preserve. Owing to their free cropping, the trees make a close growth with a mass of fruit buds.—F.

Melons.—Preparations are being made for planting the seedling Melons raised early in January. The house is thoroughly cleansed before the bed is made up. The soil is made very firm to promote a sturdy growth. Some growers prefer to plant in a small quantity of soil and add top-dressings as the growth advances, but I prefer to make the entire bed at once, using turfy loam and a good sprinkling of soot, wood-ashes, mortar-rubble, and coarse sand. Ram well as the work proceeds, finishing

off with a perfectly level surface. Then with the finest of the soil make small hillocks in which to plant. After planting insert neat sticks and secure these to the first wire of the trellis for training the young plants to. Spray the plants with tepid water when the weather is bright, and frequently damp the surroundings. Maintain a temperature of 65 degs. to 70 degs. at night, according to the conditions out of doors. Prevent cold draughts, and in the event of very cold weather cover the glass, which is preferable to using excessive fire-heat. Seeds have been sown for successional crops.—G.

Gooseberries and Currants.—Where these are grown unprotected by permanent erections of wire-netting birds are at this season of the year at times troublesome. Where this is the case, dustings with a mixture of lime and soot will be found of use in preventing the destruction of the embryo buds. It must be borne in mind, however, that copious rain or snow-falls wash off the mixture, which must accordingly be renewed from time to time as becomes needful. I have known a strong solution of Sunlight Soap—4 oz. to the gallon—equally effective, and of a more durable character than lime and soot in combination.—W. McG.

Pruning Red Currants and Gooseberries (R. S.).—Thin out and shorten back some of the longest of the branches on both kinds of bushes, leaving a goodly number of well-placed young shoots. The small side-shoots on the main branches of the Currant bushes should be cut back to two or three eyes, and slightly shorten the leading one, like a Vine is pruned; but, in the case of the Gooseberries, leave as much of the young wood in as possible, and nearly at full length. A good dressing of half-decayed stable-manure, lightly forked into the ground, would do much good, and a mulch of similar material later on would greatly assist the bushes in question.

GARDEN PESTS AND FRIENDS.

APPLE-TREE PESTS.

LAST year my trees suffered badly from Apple sucker and green-fly, and slightly from Pearmite and American-blight. The last is very bad in two adjacent gardens. The birds have just begun to eat the buds of berry bushes, and in some years I get scarcely any berries from this cause. Is there any general wash I could use now to protect buds and to destroy pests? I can get a lot of pigeon manure mixed with sawdust. Would it do harm spread on surface of Raspberry and Gooseberry plantations?—WM. CLARK McEWEN, Stirling.

[For the Apple-sucker and green-fly you cannot do better than spray the trees with a solution of Tobacco extract, for the former when the flower-buds are about to open, and, if necessary, after they have expanded, and for the latter from the middle to the end of April. The quantity of the extract recommended for use is 1 lb. to eight to ten gallons of water. The trees should also be sprayed in the winter with caustic alkali solution. Neither of the remedies is of much or any avail against American blight. Paraffin emulsion is far better. If you consult the list of various specifics sold by the leading manufacturers in the way of fungicides and insecticides you will find what you require in regard to a deterrent for preventing birds from disbudbing fruit trees and bushes mentioned therein. Neither fungicides nor insecticides are of the slightest use in coping with the larva of the Pear-gnat midge. There is no general wash to be had which would effect all you mention. As the pigeon manure is mixed with sawdust we cannot recommend its direct application to the soil in the manner suggested. Mixed with an equal bulk of soil, and allowed to lie for a year or two to become properly decomposed, it could then be either strewn on the surface or

dug in. Sawdust in a raw state breeds fungus if dug into the soil. Liquid manure cast over the heap occasionally would hasten decomposition. Adding the pigeon's dung and sawdust to a mass of fermenting stable manure would also bring about the same effect in much shorter time.]

DISEASES OF PEAS.

(Concluded from page 59.)

PEA RUST.

(*UROMYCES FABÆ*, De Bary.)

During certain years, especially when the weather has been hot and dry, Peas have been in some cases attacked by rust, which frequently causes much damage to the crop. There are three forms of fruit in the life-circle of this fungus, and all are produced in succession on the same plant. First appears the "cluster-cup" (or

various Vetches and other plants belonging to the Pea family.

METHODS OF CONTROL.—Spraying is practically of no avail against rusts. The most certain means to prevent a recurrence of the disease is to burn infected Pea-straw. If this is not done the winter-spores will be in some way returned to the land in a condition capable of infecting future crops.

PEA SPOT.

(*ASCOCHYTA PISI*, Lib.)

This fungus attacks the leaves and pods of Peas. Pale yellowish spots appear on the pods and gradually increase in size, and often encroach on each other. After a time the spots become dry, present a shrunken appearance, and are surrounded by a dark border, and the central sunken portion becomes studded with the minute black fruits (perithecia) of the summer-

stood to be due to a *Phytophthora*, perhaps *P. omnivora*, closely related to but quite distinct from that which causes the Irish or Late Blight of Potatoes.

METHODS OF CONTROL.—As this disease is often due to infected soil in the seed beds these should be sterilised. The beds should be thoroughly soaked with a solution of formalin (40 per cent. formaldehyde) in water in the proportion of 1 pint of formalin to 12 gallons of water. One gallon of the mixture should be used for each square foot of soil. After the watering is completed the soil should be covered for two or three days with coarse sacking to keep in the fumes. The watering should be done after the seed beds have been prepared for sowing, and a week or ten days should intervene between the watering and the sowing of seed, to allow for the complete escape of the formalin fumes and the drying of the soil.

Apple Royal Late Cooking in bloom in the gardens at Gunnersbury House. (See page 73.)

acidium) stage, followed by the summer-spore (or uredo-spore) condition, which forms numerous small, brown, powdery patches on the leaves, stipules, and stem. This condition reproduces itself throughout the growing period of the host-plant, and is responsible for the spread of the disease. When the plant is fading the summer-spore condition ceases to appear, and is followed, on the same parts of the plant, by a winter-spore (or teleuto-spore) stage. This takes the form of small, nearly circular blackish patches on the leaves and stipules, but the patches are often more or less elongated and streak-like on the stem. Only the spores of the winter form of fungus fruit are capable of infecting plants in the following season, and every care should be exercised in securing their destruction.

This rust, as the scientific name denotes, also attacks Broad Beans, on which it is much more general and destructive than in the case of Peas. It also attacks

spore stage of the fungus. When the pods are attacked while young they often become more or less contorted, and seed is not formed. Infected leaves soon shrivel and die. It has been stated that a fungus called *Mycosphaerella pinodes*, Stone, is the winter-fruit condition of Pea Spot.

METHODS OF CONTROL.—Spraying with Bordeaux mixture will hold the parasite in check if carried out when the earliest symptoms of the presence of the disease are observed.

BLACK ROOT ROT, BLACK NECK, COLLAR ROT.

This common and destructive disease of Sweet Peas, Asters, Antirrhinums, and many other plants, especially in the seedling stage, is characterised by a blackening of the collar or neck of the attacked plant, followed by a progressive rotting of the tissues, wilting, and rapid death. This has been attributed to attack by the fungus *Thielavia basicola*, Zopf, but is now under-

STREAK DISEASE.

The cause of this prevalent disease is still obscure, but there seems to be little doubt that in England typical streak disease is often caused by unsuitable conditions of growth, and may occur in the absence of either bacterial or fungus pests.

GENERAL METHODS OF CONTROL.—As Peas are annuals an outbreak of disease cannot be due to hibernating mycelium. There is also no evidence to show that the spores of any of the diseases discussed above are conveyed with the seed. Hence it follows that every infection must originate from some outside source. Freedom from disease must, therefore, mainly depend on preventive measures, the most important of which is promptness in destroying (preferably by burning) all diseased material, since this carries the spores, which are the only possible means of starting an infection the following season.—*Leaflet No. 287, Board of Agriculture and Fisheries.*

THE WEEK'S WORK.

OUTDOOR GARDENING.

IN BLOOM JANUARY 20TH.—*Jasminum nudiflorum*, *Winter Sweet* (*Chimonanthus fragrans*), *Genista hirsuta*, *Coronilla glauca*, *Edgeworthia chrysantha*, *Forsythia spectabilis*, *Garrya elliptica*, *Berberis japonica*, *B. Mahonia*, *Andromeda floribunda*, single pink *Camellias*, *Parrotia persica*, *Hamamelis arborea*, *H. Zuccarariana*, *Prostrate Rosemary*, *Erica carnea* (in variety), *E. alpina*, *E. mediterranea* (in variety), *E. lusitanaica*, *Daphne Mezereum* (various colours), *D. Dauphini*, *D. Lauricola*, *Pericinkles*, *Laurustinus* (in variety), *Strawberry-tree*, *Narcissus paltidus præcox*, *Lithospermum Heavenly Blue*, *L. rosmarinifolium*, *Iberis petraea*, the *Corsican Hellebore*, *Lenten* and *Christmas Roses* (in variety), *Primroses*, *Crocus Imperati*, *C. susianus*, *Aconites*, *Blue-eyed Mary* (*Omphalodes verna*), *Violet Cress*, *Polyanthus*, *Carpathian Snowflakes*, *Viols*, *Winter Heliotrope*, *Aubrietias*, *Tufted Pansies* (various), *Algerian Iris*, *Snowdrops* (in variety), *Cyclamen Coum*, *Triteleia uniflora*, *Polygala Chamæbuxus purpurea*, *Mecaseca*, *Saxifraga apiculata*, *Anemone coronaria*, *Hepaticas*, *Anemone blanda*.

WORK OF THE WEEK.—A very large tree of the Willow-leaved Pear, having outgrown the space allotted it, has been well thinned out, being careful not to disfigure the tree, which is clothed during the summer with a fine old Rose and Clematis, to which has been added a plant of Polygonum Auberti. A small group of Clerodendron Fargesii planted a few years ago on a south border having pushed its suckers to an alarming extent among neighbouring shrubs, which they threatened to envelop, has, with the exception of one specimen, been dug out and the largest transferred to the home woods. A group of the fine scarlet Rhododendron Doncaster has been planted. *Abutilon vitifolium*, not making any headway where it was, has been transferred to a warm, sheltered border. *Lonicera pileata* is a charming dwarf evergreen shrub of the easiest cultivation. A plant having been put at the back of some taller-growing shrubs, it was decided to transplant it to a position where it could be better seen. All the lower part of the bush was found to have rooted wherever the branches had come into contact with the soil, and we were thus able to get a nice-sized group by severing these from the parent shrub and planting singly. A few more Hepaticas have been put out. Some of them are commencing to bloom. Pruning is still going ahead. The yellow *Jasminum nudiflorum* has been so beautiful this year that every shoot required for extension has been tied in, and, where possible, a few growths have been brought to the ground and a flat stone laid over them. In this way we find they root freely and may be detached from the parent plant the following season and planted separately. Having a few *Othonnopsis cheirifolia* to spare, a place was found for them on the ridge of a sunny bank over which the interesting blue-grey glaucous growths may fall freely. This plant revels in plenty of sunshine. The forking over and clearing up of shrub-berries are being carried out when the weather is at all favourable. A long and wide line of Violets which graces a retaining wall has been freshened up, cleaned, and top-dressed with a little fresh soil, and a line of flat stones placed upon their roots to dispel drought in

summer. Cuttings of a variety of the purple Willow called *Scharfenbergensis* have been put in by the waterside. E. M.

Sussex.

SOUTHERN COUNTIES.

Fruit-tree planting.—Several old trees having been blown down recently by rough winds and a few lost from old age in the orchard, the vacancies will be made good. The new trees will not, however, be planted in the places where the old ones stood. Plums will be planted where Apples previously stood, Apples in place of Plums; while Pears will succeed Apples. Holes $4\frac{1}{2}$ feet in diameter will be opened out two spits deep, the top spit, including the turf, placed on one side for putting into the bottom of the holes after the hard base has been loosened with a digging-fork. Stout stakes for the support of the trees (standards) will be driven in before planting and sufficient soil of a better quality for placing over and between the roots will be got ready by the side of each hole. Lengths of wire-netting to protect the stems of the trees from rabbits will also be got ready to put round them when planting is completed.

Scions for grafting.—These should be selected without further delay, tied in bundles, labeled, and heeled in under the north side of a wall or hedge to keep the bark firm and plump and the buds dormant. The stocks should now be partly cut back, whether they consist of young stocks not having yet been grafted or established, healthy trees on which it is desired to work another variety. In the latter instance the cutting back should be done in such a manner that shapely heads will result when the scions make growth and in due course furnish the trees anew with branches. In regard to Apples no scions should be taken from trees infested with American blight, nor from those which have been subject in the past to scab, black spot, and other fungoid diseases.

Propagation of Currants and Gooseberries.—As has on previous occasions been mentioned, it is always a good plan to have a reserve of bushes to which to resort for the making good of vacancies caused by death and so forth in the quarters. Both are easily propagated from cuttings, of which an ample supply is ready to hand beneath the recently-pruned bushes. Those of medium size and having the wood well ripened are the most suitable. The making can be deferred until a wet day occurs. In the meantime the cuttings must be kept from shrivelling by heeling them in to about half their length in a cool, damp position. No Gooseberry cuttings should be saved from bushes which have suffered from "mildew" in the past.

Spraying.—Work among hardy fruits is now sufficiently advanced to allow of a start being made with the spraying of the trees. By the time the spraying of those on walls is finished, pruning, the orchard excepted, will have been brought to a conclusion. As usual, a preparation which acts both as a fungicide as well as an insecticide will be used, this being applied at a less strength to Apricots, Peaches, and dessert Cherries than to other kinds of fruits. This dissolves readily in warm water, but the hotter the water the more searching is its effect when applied to the trees. The great difficulty in connection with spraying is to secure a period of calm weather in which to carry it out. If a breeze springs up the work has to be suspended and delay occurs. If persevered with, waste results, and spraying done under such conditions is never so effective

as when the operator is able to direct the spray on to all parts of the tree without let or hindrance.

Plant-cleaning.—Before the season becomes too far advanced it is the rule to give the occupants of the stove a thorough cleaning, using an approved insecticide for the purpose. Sponging cleans the foliage, but for mealy-bug on Gardenias and scale on Crotons or other plants small, stiff brushes are required to remove them. The cleaning requires to be carefully done, otherwise the foliage is damaged and the beauty of the plants marred. For creepers on the roof a galvanised foot-bath is a capital receptacle in which to lay and clean the various portions of the growths as they are detached from the trellis. If a sufficient quantity of insecticide is diluted to the proper strength and placed therein it can be made to do duty not only for cleaning creepers, but other subjects as well. The opportunity is also taken to give the interior of the house a good cleansing and to perform the requisite amount of whitewashing afterwards. After such a cleaning of both house and occupants no further trouble for a considerable time need be apprehended. A point is made of fuming the house periodically with a nicotine compound which keeps mealy-bug under.

Cattleyas.—These are also carefully cleaned at the same time. The principal insect foe to contend with in their case is the "stock seed scale," which secretes itself in the axils of the leaves and beneath the scaly covering of the pseudo-bulbs, and therefore requires care and judgment to effect its dislodgment without injury resulting either to the leaves or the dormant buds or breaks at the base of the pseudo-bulbs. For this reason the cleaning has to be entrusted to those conversant with the nature and habit of growth of such plants. Other species of Orchids will be looked over at the same time, after which the roof-glass, woodwork, and stages will be scrubbed down and a rearrangement of the plants afterwards carried out.

Lothian Stocks.—These have now been shifted from $4\frac{1}{2}$ -inch pots to those 6 inches and 7 inches in diameter, the compost employed being rich and made firm round the balls with a potting-stick. As a certain percentage of the plants will yield single flowers, allowance for this has been made by potting rather more of each variety than are actually required. Surplus plants are stood in a cold frame until they can be planted outdoors, where they flower considerably in advance of plants raised from seed sown at the present time. Until the flower-spikes begin to show and push up, the plants in pots will be kept on a shelf where they can have an abundance of light and air. To obtain a really fine display in beds and borders of Lothian Stocks the seed should be sown now. This is best done either in pans or boxes, as the seed can then be thinly distributed, with the result that the seedlings are sturdy. Slight warmth is needed in which to raise the seed, and after the seedlings appear they require a position where they will be close up to the light. A sandy compost is best for filling the pans or boxes with, with a thin layer of the same passed through a fine sieve and placed on top. This should be well watered with a fine rose before the seed is sown. The seed should be lightly covered with fine soil and shaded until the seedlings appear.

Tuberous Begonias.—Seed of both single and double varieties should be sown without further delay if plants are required for autumn blooming. As the seed is very fine great care is necessary when sowing. Heat

is necessary for the successful raising of the plants. The fibrous-rooted varieties for the flower garden should also be raised in the same way if good, strong plants are required.

Vine eyes.—It is time these were inserted either in turves, pans, or small pots. The last are by far the best, as no root-disturbance follows when the time arrives for shifting them into larger pots. The eyes must be taken from sound, thoroughly-ripened wood. Those situated near the base of the laterals are generally found to be the most satisfactory. The eye should be cut, with about $\frac{1}{2}$ inch of wood remaining on either side of the bud, and the under part pared flat to about half of its depth. The pots should be filled to within an inch of their rims with rich, loamy compost. Some sand should first be placed on the soil. On this place the eyes and then cover with soil, leaving nothing but the bud showing on the surface. Well water and plunge the pots in a propagating-case or in a bed of leaves in a house where forcing is being conducted.

A. W.

It is not advisable to disturb the roots after the plants have commenced to grow. The compost used for potting consists of good fibrous loam and peat, adding sufficient broken crocks and charcoal to keep the soil porous. Ferns should never be over-potted. Specimen plants may be kept healthy and in a thriving condition in pots of a moderate size with the aid of liquid manure during their growing season. Ferns are most useful for decoration when in small pots.

Liliums, Gladioli, and other bulbous plants plunged in cold frames are inspected occasionally, and as growth progresses are gradually inured to the light. A batch of

Gloxinias has been placed in the forcing-house, selecting those which already show signs of starting. The tubers have been stored in boxes and slightly covered with fibre, therefore they can be easily examined. A light, rich soil suits Gloxinias, and for the first potting I consider it unnecessary to add any manure. Start them

shoots and retaining as much of the strong wood as possible.

Penzance Briars are vigorous growers and suitable for forming hedges or screens. They are seen at their best when allowed to grow at will, very little pruning being necessary.

Austrian Briars are very beautiful, and a good specimen in bloom always attracts attention. The plants are not strong growers, therefore little pruning is necessary, the principal requirements being the removal of weak and worn-out shoots. The flowers are produced on shoots of the previous year. Any old Rose-trees which are showing signs of exhaustion should have a good portion of the surface-soil removed from about the roots and replaced with good loam and well-decayed farm-yard manure.

Jasminum nudiflorum.—This is now in fine bloom. It is often spoilt through neglect of pruning, thus allowing of accumulations of annual shoots that assume, as time goes on, a faggot-like form. The proper time to prune this plant is im-

Fatsia (Aralia) japonica in a bronze bowl.

MIDLAND COUNTIES.

Vineries.—Preparations for forcing having been made by washing the interior of the houses, thoroughly cleansing the Vines, watering and top-dressing the borders, the forcing of successional Vines and Muscat varieties will now be commenced. The Muscat of Alexandria and other Muscat Grapes require a long season of growth and skilful management to bring the fruit to perfection. The Vines which are to furnish the principal crops should be started early in February, so that the fruit may colour well and ripen perfectly. The vineries should be closed and a night temperature of 50 degs., rising to about 65 degs. by sun-heat, be maintained, the Vines and the interior of the vinery being syringed two or three times daily.

Early Peaches.—Trees which have set their fruits and are beginning to grow should be disbudded gradually, removing all fruits that are deformed or badly placed.

Ferns will now be given a general overhauling and those that require it repotted.

in a minimum temperature of 60 degs. in a moist atmosphere.

Pruning climbing Roses.—All the pruning necessary for climbing Roses growing where their extension is unnecessary is the removal of weak and superfluous shoots, together with dead and diseased branches, but specimens growing on pergolas, pillars, or walls need a more severe pruning. The best time for the work is immediately the flowers are over, as the plants have then practically the whole of the season in which to develop their growth. If the old flowering shoots were removed entirely and the new shoots that developed from the base of the plant thinned according to the amount of space to be furnished, all that is necessary is to cut off the unripened ends of the branches and secure them before growth recommences. The thinning of the shoots of climbing Roses has often to be deferred until the plants are given a general overhauling in the winter, and where this is the case the pruning must be done very sparingly, cutting out only old and weak

shoots immediately the flowering season is over. This may consist, in old plants, in the cutting away of much of the older wood, so that the new shoots may develop flowering twigs for the following season.

Autumn-sown Onions succeed best when raised in a seed-bed and transplanted to well-prepared ground early in spring. The transplanting of these will be done as soon as the weather is favourable. Being perfectly hardy their roots will commence to grow, provided the ground is not frost-bound. A few days before planting, the ground (which was previously trenched and manured) will be pointed over with a fork, adding a good dusting of lime and soot, after which the surface is raked finely. Place the plants at distances of 12 inches from each other, leaving 15 inches between the rows. This is an important crop, as the bulbs are ready at a time when good Onions are scarce.

Shallots should be planted as soon as the soil is dry enough, choosing a light, sandy border. Plant in lines 1 foot apart, simply pressing the bulbs into the soil at every

10 inches. Nothing more will be necessary until growth commences, when the soil between the rows should be lightly stirred with a Dutch hoe. Garlic should also be planted, allowing a space of 18 inches between the rows.

Potatoes growing in pits must be afforded plenty of fresh air whenever this is possible. If further plantations have to be made the soil should not be less than 9 inches deep. This will lessen the need for frequent top-dressings and waterings. Where it is impossible to devote a pit to Potatoes a few may be grown in pots. Three sets are sufficient for a 10-inch pot. The pot should be liberally crocked and half-filled with loam and leaf-mould in equal parts. The sets should then be planted, leaving the remainder of the space for earthing up the plants as growth advances. They must not be subjected to excessive heat or overwatered during the early stages of growth.

Digging and trenching.—This important work is in arrears, owing to the excessive rainfall during December, and must be pushed forward as quickly as possible, so that the soil brought up from the bottom may receive all the benefit possible from the winds and frost which may occur between now and the time for seed-sowing and planting. On heavy land it is not advisable to attempt this work when the ground is in a soddened condition, full advantage being taken of all dry weather.

F. W. GALLOP.

SCOTLAND.

Rose-planting.—This, which had been delayed on account of bad weather, was completed in the course of the week. The varieties dealt with were principally of the climbing sorts and included Dorothy Perkins, White Dorothy, Crimson Rambler, and Hiawatha, with a few pieces of Excelsa. As the situation in which these were planted is rather exposed the newly-planted specimens were afforded as much shelter as possible by pleaching long branches of Laurels round the fence in their immediate neighbourhood, which will, to some extent, break the severity of the winds which at times blow strongly from the east and the south-west. At the same time additions were made to the Hybrid Tea Roses in beds.

Hardy fruit.—The weather having improved in the earlier part of the week, further progress was made with the tying and training of Peaches and Nectarines in the open, and it is hoped that this work will be completed in the course of a day or two. This will finish the work upon the walls, and afterwards the whole of the trees will be given a mulch. Opinions differ as to the best time at which to mulch, but from observation I think that there is no time like the present. The soil is, as a rule, in a good state as regards moisture, and if mulching is resorted to at this time it protects the surface roots from any temporary dryness when the searching winds of spring begin, and which sometimes dry up the surface of the soil rapidly at a time when watering cannot very well be attended to. In the course of the week, also, the latest plantation of Raspberry canes was attended to. This plantation is now entering upon its third season of bearing, the canes are well matured, numerous, and strong, so that, as is usual in these gardens, a good return is anticipated. After training was completed the quarter was lightly forked up, and when time permits it will be top-dressed either with half-decayed manure or with decayed sifted vegetable mould, of which a good quantity is available.

Vegetable garden.—A considerable amount of digging has been done during the week. For a long time this work was put an end to by incessant rains, and even now the soil is in a rather sodden condition. Trenching is always preferred when possible, but with the advancing season there will be little time to trench, so that deep digging must be resorted to. Decayed and rotten leaves are regularly picked from among green vegetables, which continue to be plentiful and will provide sufficient material for a prolonged period. Leeks appear still to be growing. Savoys are useful, and Coleworts are not without value. Sprouts are firm and hard, the latest batch exceptionally so. I prefer to use a dwarf variety for the latest planting, as the plants do not suffer so much as the giant varieties from snowfalls or other extremes of winter weather. Seakale and Rhubarb from forced crowns are now in use, and further supplies have been put in.

Seed-sowing claimed attention in the course of the week. Among flower-seeds a good sowing of Lothian Stocks was put in. These ought to be sown early when they are intended to bloom in the late summer. Given a little heat in their early stages good plants can soon be worked up. These, if well hardened off, may safely go out in early May. Seed of Begonias, Lobelia, Ageratum, and Gloxinias was also sown, but the main sowings will be deferred until next month. Sowings of vegetable seeds included a few pans of Onions. The varieties preferred are Cranston's Excelsior and Ailsa Craig—two Onions which for general purposes yet hold their own. A small quantity of Leek seed was also sown for special purposes, but as there is always a danger of the plants from the first sowing bolting, a further sowing will be made in a fortnight's time. At the same time a sowing of Parsley was made, plants from this generally being useful to supplement the failing supply from beds or frames in late spring. Where Melons, Cucumbers, and Tomatoes are required, sowing ought not to be very much longer delayed. At this dull time rapid germination is needed in order to secure strong plants, and a heat of 80 degs. or 85 degs. is requisite. In the case of the flower and vegetable seeds referred to, a heat of from 60 degs. to 65 degs. will be ample, and after germination takes place care is necessary to prevent damping among the seedlings.

Stock-taking.—From time to time, as opportunity offers, stock is being taken of all plants in hand. It is always advisable to do this early in the season, so that there may be—in the case of bedding plants especially—no scarcity of any subject which may be required throughout the year. Propagation now is more easy of accomplishment, and should there have been any casualties during winter the losses can soon be made good. At the same time estimates ought to be made of the possible quantity required of each variety. After a few years' experience one can generally form a pretty good idea of the necessary numbers, but at the same time it is always better to have a few plants too many. A 10 per cent. margin is, generally speaking, quite safe, and allows for deaths or accidents after planting.

Propagating-pits should now be overhauled and cleaned. These, during the spring, are so indispensable that a little attention at this time is well repaid. Some use sand as a rooting medium, others prefer a mixture of sand and finely-sifted soil, but I find nothing equal to Cocoa-fibre, with the addition of a little finely-crushed shells. This mixture seems to

suit practically everything which is inserted—the cuttings root quickly and damping is unknown. If there are about 4 inches of fibre in the pit it will be found that it generates a mild bottom-heat which is lacking in the case of sand, or of sandy soil, and which is of much advantage when hot-water pipes are not led through the pit. Further, when fibre is used there is no danger from slugs, which, however careful one may be, are almost certain to be introduced when soil mixtures are used.

Pot Vines will make progress at the roots as soon as the foliage begins to move. They will then require a stimulant in the form of diluted liquid manure or of chemical fertilisers in solution. A further advantage will ensue if the pots can have a zinc collar affixed within which well-decayed fibrous old loam can be packed over the surface roots.

Plant-houses.—During the week pressure of other work has led to plant-houses receiving only the needful attention in respect to watering, ventilation, and firing. Owing to the rather sunless weather damp is more pronounced than usual, and a trifle more fire-heat than is usually necessary has been given, with, of course, as much ventilation as possible. Watering is done in the early part of the day, and, meantime, the ordinary washing-down of pathways is suspended. W. McGUFFOG.

Balmac Gardens, Kirkcudbright.

ROYAL HORTICULTURAL SOCIETY.

JANUARY 25TH, 1916.

THE fortnightly meeting held on the above date was of unusual interest for the season of the year, the earliest alpine—much earlier than usual by reason of the genial weather conditions—constituting a show in themselves. Of considerable charm was the representative collection of Violets from Corfe Mullen, finer than which have rarely been seen. Perpetual-flowering Carnations, too, were very fine, though not numerous shown, while early-flowering and other shrubs, with greenhouse plants and Ferns, contributed not a little variety. Orchids were freely and well shown. Many boxes of Canadian-grown Apples were on view.

HARDY FLOWERS.

These, coming from many sources, were for the most part well grown and nicely displayed. Without doubt one of the finer collections was that from

Mr. Maurice Prichard, Riverslea Nursery, Christchurch, Hants, his lot including a choice assortment of alpines, chiefly Saxifrages, with Lenten Roses and other things. Of the former the colonies of S. Elizabethæ, Mrs. Leng, apiculata, and Haagii, all yellow-flowered sorts of easy cultivation and much merit, were very effective, while such as S. Burseriana Gloria and S. B. tridentina (white-flowered) were a considerable attraction. The very shy-flowering S. Salomoni, one of the best of the small-growing, encrusted carpeting kinds, was full of bud and blossom. It also is white-flowered. Saxifraga (Megasea) speciosa rosea is a particularly good-coloured form and flowering well at this season is most welcome. Lenten Roses were beautiful or quaint, and always of interest.

Messrs. William Cutbush and Sons, Highgate, N., showed in excellent taste good, well-flowered tufts of Christmas Roses; also hardy Heaths, Hepaticas in red, white, and blue, Iris alata, and such choice Saxifrages as Kestonensis (very pure white), S. Burseriana major, and S. Boydi alba. Daphne japonica was also remarked. Forsythias, Prunus triloba, and others were in the background.

Mr. G. Reuthe, Keston, Kent, had many interesting plants, both flowering shrubs and alpines. Of the former none were more effective than the handsome flowering growths of *Berberis japonica*, which provide a wondrous profusion of yellow, fragrant flowers naturally at this season. Choice *Rhododendrons* as *moupinense* (white, copiously-spotted crimson), and *R. mucronulatum* and *R. dahuricum semper-virens* (both with reddish flowers) are also welcome now. *Ribes laurifolium*, in flower, was among rare things, though there were many of the choicer alpines on view.

Messrs. Waterer, Sons, and Crisp, Twyford, arranged a rock bank, planting it with alpines and shrubs. The finer flower masses were created by *Saxifraga Boydi* alba, *Soldanella alpina*, and *Sisyrinchium grandiflorum*, a plant we see all too rarely in established clumps in the garden.

Messrs. Whitelegg and Page, Chislehurst, also had a considerable display of alpines, showing among others the fine encrusted *Saxifraga calabrica*, which, however, was not in flower. Of those in bloom *S. coriophylla* and *S. Boydi* alba (white), *S. Faldonside*, *S. apiculata*, and *S. Elizabethæ* were all arranged in ample groups.

Messrs. Herbert Chapman, Limited, Rotherside Gardens, Rye, who specialise in early bulbous Irises, showed a nice assortment of these plants, the fine blue *I. Cantab* being very conspicuous. Others, as *I. Tauri* and *I. sind-pers*, were in smaller numbers, while a batch of seedlings contained many promising things. *Iris Little Bride* (whitish falls and bluish-white standards, almost an albino reticulata) gained an Award of merit.

Mr. Clarence Elliott, Stevenage, showed the best-flowered batch of *Saxifraga Boydi* alba we have seen for a long time, a score or two of plants being studded with the handsome pure white flowers. *S. Burseriana Gloria* was very good, the new pink-flowered *S. Irvingi* and the yellow-flowered *S. Faldonside* appealing respectively as the newest and best of this valuable race.

Messrs. Piper, Bayswater and Barnes, also had an extensive lot of alpines.

VIOLETS.

The superb gathering of Violets from Mr. J. J. Kettle, Corfe Mullen, near Wimborne, was a great attraction, as welcome for fragrance as for the handsome bunches of well-grown flowers. Nearly forty varieties were displayed, and it is only rarely that such cultural excellence is observed at an exhibition. *La France* still leads as the finest single dark, *Luxonne*, *Ascania*, *Admiral Avellan*, *Princess of Wales*, and *Wellsiana* being all worthy sorts. The finer doubles were *Colcroonan* (rich lavender), *Jamie Higgins* (silvery-mauve), *La belle Parisienne* (an improved *Marie Louise*), *Mrs. J. J. Astor* (of reddish hue, very distinct), and *Mrs. J. J. Kettle* (a silvery-mauve novelty and one of the best of recent additions).

CARNATIONS.

These were in uncommonly good condition, the fine quality due, in no small degree, doubtless to the almost entire absence of fog this winter.

Messrs. William Cutbush and Sons, Highgate, N., showed their new perpetual Malmaison variety *Sabina*, a handsome flower of rich scarlet. The lovely salmon-coloured *Lady Ingestre* was very well displayed, while *Mrs. Mackinnon*, *White Swan*, and *Triumph* were noted among others.

Messrs. Allwood Brothers, Haywards Heath, arranged an extensive assortment

of high-class blooms. Some good novelties were here, particularly in the fancy class, *Mrs. B. P. Cheney* (white and scarlet), *Rosalind* (the best yellow-ground so far), and *Brilliant* (white fancy with maroon markings) being some of them. *Mary Allwood*, we think, has but rarely been better, the brilliant colour catching the eye at once. *Rosette* was the best *crise*, *Terrific* and *Mrs. C. F. Raphael* (pink and scarlet respectively) representing the perpetual-flowering *Malmaisons*.

Messrs. Stuart Low and Co., Enfield, also contributed handsomely of these flowers, their more striking sorts being *Mrs. Mackay Edgar* and *May Day Improved*, both of the clear salmon tone so much valued. *Philadelphia* stood out well among *crise*-coloured sorts; *White Wonder* and *Matchless*, indispensables in the white-flowered set, were also prominent. Messrs. Stuart Low also showed *Cyclamens* well.

GREENHOUSE FLOWERS AND FERNS.

Messrs. H. B. May and Sons, Limited, Edmonton, had an excellent group of greenhouse and hardy Ferns associated with groups of *Cinerarias*, *Euphorbia jacquiniæflora*, and *Primula japonica* in variety. Among Ferns, *Polypodium gluticum crispum* and *Adiantum Farleyense gloriosum* were prominent, the former striking and distinct, the latter one of the most graceful and beautiful. The hardy evergreen *Scolopendrium* were in considerable variety, such as *S. vulgare crispum Robinsoni*, and *S. v. grandiceps*, one of the best tasselled sorts, being noted.

Messrs. W. Wells, Limited, Merstham, had excellent stands of the late pink-flowered *Chrysanthemum Bertha Lachaux*, which should prove of much value. *Carnation Aviator* (rich scarlet) was well shown.

Messrs. Carter and Co., Raynes Park, exhibited an excellent lot of *Primula sinensis*. Of these *Princess May* is, without doubt, the gem of the pink-flowered lot, and, while of delightful colouring, produces a well-developed truss of handsome flowers. *Fairy Queen* is one of the best of the stellata group, an Apple-blossom association of pink and white that is singularly pretty. *Carter's White* belongs to the same section and is very pure and good. *King Edward VII.* is one of the large-flowered class and pure white.

SHRUBS.

Messrs. J. Cheal and Sons, Crawley, sent some interesting things in this section, the male and female forms of the Alder and the male form of *Hippophæ rhamnoides* being among the number. *Hamamelis* in variety, *Forsythias*, *Cydonias* of sorts, and *Garrya elliptica* were also remarked.

Mr. L. R. Russell, Richmond, showed two varieties of *Hamamelis Zuccariniana*; also *H. arborea* and *H. mollis*, all welcome at this season of the year. The groups of *Daphne Mezereum* and *D. M. alba* were particularly good.

ORCHIDS.

Sir Jeremiah Colman, Bart., Gatton Park (gardener, Mr. J. Collier) sent a remarkable exhibit of *Cymbidiums*, the chief of which were raised by him. They were in great variety, pink, rose, buff, yellow, and other shades. *Lady Colman Golden Queen* was one of the more distinct in a particularly good lot.

Messrs. Sander and Sons, St. Albans, had many well-flowered examples of *Dendrobium Wardianum giganteum*; also *Cattleya Snow Queen* and *Lælio-Cattleya J. F. Birkbeck* among others.

Messrs. Armstrong and Brown, Tun-

bridge Wells, showed superbly-flowered examples of *Miltonia Blueana*, the rare and beautiful *Cattleya Percivaliana alba* with *Odontoglossum Anzac*, and the fragrant white-flowered *Pilumna nobilior*. In a central group were several seedling *Odontoglossums* of much promise.

Messrs. J. Cypher and Sons, Cheltenham, had a group rich in *Cypripediums*, the pick of which were *C. Thompsoni*, *C. aureum virginale*, and *C. Lecanum Clinkaberry-anum*. *Sophronitis grandiflora* was brilliant at the margin; there were also good *Calanthes* and *Brassó-Cattleyas*.

Messrs. Charlesworth and Co., Haywards Heath, had some exceptionally good *Odontiodas*, of which *Langowoyi* and *O. Juan* in two distinct shades were the best. *Odontoglossum Lambeauianum* var. *Lyoth*, *O. Louise*, and *Sophró-Cattleya Saxa*, a most brilliant flower, were noted.

Messrs. J. and A. MacBean, Cooksbridge, contributed *Odontiodas*, *Cymbidiums*, and a nice lot of *Lælia anceps Williamsiana* (pure white with crimson markings), and *Odontoglossum Fascinator aureum*.

FRUIT.

Mr. J. A. Baker, M.P., Harlesden, showed cases of Canadian Apples, including such as *Northern Spy*, *Phœnix*, *Baldwin*, *Canada Red*, and others.

Mr. J. C. Allgrove, Middle Green, Langley, sent a dish of the late dessert *Pear Mrs. Seden*, a cross between *Seckle* and *Bergamotte Esperen*. The fruits, which are of medium size, are firm and juicy.

A complete list of the certificated plants and medals for groups appears in our advertisement columns.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Azalea leaves unhealthy (*G. A.*).—The leaves sent are badly attacked by thrips, caused by an overdry atmosphere. The affected plants should be frequently syringed with diluted Tobacco-liquor, or some other good insecticide, laying them on their sides, and getting at the under sides of the leaves. Forceful syringing (in the same way) with pure water will also do good.

Montbretias (*D. A.*).—As a rule, *Montbretias* flower abundantly if not too crowded, but in suitable soil their increase is so rapid that in a few years a solid mass of corms is formed. If allowed to get into this state the flowers will be few and far between. As soon as it is seen that the plants are crowded they should be lifted and replanted, the corms being placed from 2 inches to 3 inches apart, according to their size. The best time to lift is immediately the flower-spikes have shed their blossoms, as the corms then throw out roots before the winter sets in.

Increasing Aspidistras (*D. G.*).—The way to increase this plant is by division. In the spring, before growth commences, turn the plant out of the pot, wash the soil away from the roots, disentangle them, and then divide in pieces as may be required—say, in the case in question, divide the plant into four portions—re-pot these in good loam and sand, and place them in a temperature of 55 degs. to 60 degs. Keep rather close and moist for a time, and they will soon become re-established, when they can be gradually inured to full exposure to the air. After potting be very careful with the watering, as if too much water is given before the roots are moving freely in the fresh soil the plants will suffer.

Camellias doing badly (*R. W.*).—Your planted out trees are in bad condition, due to the beds being a mass of fungus, and doubtless the drainage is bad. Now is a good time to remedy this defect. Lift the plants this month or March, and clear out the old bed, giving new drainage and fresh soil, using plenty of turfy loam and peat, broken charcoal, and coarse sand. Many do not advise rough peat, but your plants will need it. You will, no doubt, find many of the large roots decayed. Replant firmly, and, if possible, shorten the tops where the foliage is bad. The conservatory must be kept much warmer for a time to encourage new growth. Also shade the trees, and syringe them overhead several times a day.

Asparagus plumosus (*Pteris*).—This is now taking the place of the *Adiantum*, and rightly so, for as a pot plant it stands the dry atmosphere of a room much better than a Fern, and when cut there is no comparison between

the two, either in point of lasting or lightness of appearance. This Asparagus, if grown for cutting, must have plenty of root-room, and for this reason it is much better planted out, using a light rich soil for it to root into. Grown thus it is astonishing the number of fronds that is cut from the plants. Young growths which start up from the bottom in the course of a few weeks will be from 10 feet to 12 feet long; the branches from these soon developing and being ready for cutting. Pieces may be had of all sizes, from 6 inches to 2 feet in length, and about the same in width.

TREES AND SHRUBS.

Ruscus racemosus (B. B.).—The specimen sent is the Alexandrian Laurel (*Ruscus racemosus*), a near relative of the common Butcher's Broom. It is quite hardy and not particular as to soil or situation, but it succeeds best where moderately moist and in a partially shaded spot. It is at home where associated with the hardy Bamboos, to some of which it bears a certain amount of resemblance, for the slender shoots, which are pushed up to a height of 3 feet to 4 feet, have a good deal the aspect of a Bamboo. Apart from its desirable features as a graceful evergreen shrub, this *Ruscus* is very valuable for cutting, as the slender shoots, clothed with their deep green foliage, are most effective when arranged in a vase, particularly if lit up by a few flowers. In this way the sprays keep fresh and bright for a long time; indeed, it is one of the most durable evergreens that we possess for such a purpose.

FRUIT.

Retarding Vines (T.).—You should prune your Vines at once close up to the rods; but your other question as to keeping them back is difficult, as you want to keep the house full of plants that require a temperature through the winter sufficient to start the Vines. We see no way out of the difficulty, unless you can get the Vines rods outside for the next two months; the other alternative being to keep your house much cooler and not study the plants, as your Vines under present conditions cannot rest. Vines at rest should have no fire-heat of any kind.

VEGETABLES.

Pithy Celery (A Kitchen Gardener).—The cause of your Celery going pithy is a check of some kind; it is often caused by rank manures at planting. Too early moulding checks top growth, and in soils like yours early moulding up in a wet season would have a tendency to cause such growth. Another, and the worse fault, is allowing a crowded growth before planting in the trenches. If the plants get a check in the seedling stage they never recover, but make a pithy, deformed growth.

Planting Rhubarb (A. H.).—Divide your large roots of Rhubarb late in February or early in March, the exact date depending upon the weather and state of the soil. As you want the roots for forcing next December, cut them up into, say, three to four pieces, each piece having two or three crowns. Plant in deep-dug, well-manured land at a distance of 3 feet between the rows and 2 feet between the roots, planting firmly and in an open, exposed position. Cover the surface with short manure after planting, and do not allow the flower-spikes to grow. The plants come true from seed if you only have one variety in bloom at the flowering time. Sow early in March—in a frame, if possible, or on a warm border in the open later.

SHORT REPLIES.

A. O.—Suspend two or three thicknesses of ordinary fishing-net in front of the trees, resting the net on Bamboo poles fixed in the ground and leaning on the top of the wall. This will be quite sufficient. We hope to deal with this subject in an early issue.

NAMES OF PLANTS AND FRUITS.

Names of plants.—*A Regular Reader.*—*Habrothamnus elegans Newellii.*—*B. B.*—The specimen you send is the Alexandrian Laurel (*Ruscus racemosus*). See also note on this page.—*Evelyn G. Smith.*—The tubers you send are probably those of an *Oxalis*, but without flowers it is hard to say. Pot them up in some sandy loam, and stand them in the greenhouse. When leaves and flowers appear, please send same on, and we will do our best to help you as to the name.

Names of fruits.—*G. S.*—Apples: 1, Adam's Pearmain; 2, Ribston; 3, Annie Elizabeth.

AUDITORS' REPORT.

We have examined the above Balance Sheet and compared it with the Books at Lothbury and Lombard Street, and the certified Returns received from the Branches.
 We have verified the Cash in hand at Lothbury and Lombard Street and at the Bank of England and the Bills Discounted, and examined the Securities held against Money at Call and Short Notice, and those representing the Investments of the Bank.
 We have obtained all the information and explanations we have required, and in our opinion the Balance Sheet is properly drawn up so as to exhibit a true and correct view of the state of the Company's affairs according to the best of our information and the explanations given to us, and as shown by the Books of the Company.
 FRED. JOHN YOUNG, F.C.A., } *Auditors.*

NOTES OF THE WEEK.

Spring flowers in Scotland.—Snowdrops are now (January 15th) fairly numerous, though later than usual. The Winter Aconite, like Snowdrops, is later than usual. The Vernal Snowflake looks as if it will be in flower about the usual time, and Iris reticulata promises well at the foot of a Peach-wall in company with *I. stylosa*.—W. McG., *Kirkcudbright*.

The Servian Quinces.—Some people are at last recognising the value of the two Servian Quinces introduced some years ago by Lemoine, of Nancy. The one is called *Cydonia Vranja* and the other *Cydonia Leskovatz*. They both require to be grown in a similar way to Apples, but then produce fruit of an enormous size and good flavour for mixing with Apples when cooked. In warm summers the fruit is beautifully coloured—yellow and red.—R. H. BEAMISH.

The Winter Jasmine in Scotland.—The general opinion in this district is that the display upon the Winter Jasmine at present is the best for a series of years. After the flowering season last spring, and just after the annual pruning, the weather was exceptionally mild, and that, combined with, on the whole, suitable conditions throughout the season, is responsible for the fine show. The value of *Jasminum nudiflorum* on walls at this season is great, and, when cut, the sprays last for a long time in water.—W. McG.

Adonis amurensis.—Nestling under the branches of the Yellow-barked variety of the Dogwood, *Adonis amurensis* has again come into bloom. This Amoor River *Adonis* is very welcome. It is partly shaded, but the Dogwood allows what little sun we have had to reach the flowers, so that they open on bright days. Even in stormy weather the closed blooms give the touch of gold we love in the dull season. I find a light loam suits it quite well, and it evidently does not object to the roots of the Dogwood robbing the soil of some of its nourishment.—S. ARNOTT.

Primula denticulata.—On January 19th the flowers of this *Primula* were showing colour, despite the continual rainfalls which have been experienced of late. This and *P. d. cashmeriana* thrive here in almost every position, flourishing alike in cold, heavy soil, in lighter and more porous mediums, and in the rock garden. Some of the finest pieces of last spring grew in a gravel walk upon which the seed had

been blown. Indeed, so suited are the conditions to its well-being that annually sturdy seedlings have to be hoed out of the walks which, in places, become perfectly green with them.—W. McG., *Kirkcudbright*.

Peat-ashes.—In reply to "R. B." (page 50, assuming that the Peat referred to is similar to that which is used for fuel in parts of Scotland, the ashes are distinctly useful. As "R. B." is probably aware, these are very fine and white, so that some considerable consumption of the material would be required to obtain a good bulk of ashes. These must be kept dry until required, for if wetted, even once, a proportion of their value is destroyed. Like wood-ashes, these can be utilised for Potato ground, for sowing in the drills prepared for Carrots or Onions; indeed, for any purpose for which wood-ashes are adapted. Peat-ashes are further valuable in potting composts, more particularly in the case of Ferns.—W. McG., *Balmae*.

A note from Hurst Court.—January at Hurst Court is like spring. A fortnight ago (January 15) I saw partridges paired, a most unusual sight so early. Violets (white and blue) are in flower and Peaches in bud. Weeping Willows are covered with golden-green leaves, and though *Lonicera fragrantissima* has been out a month and Double Daisies are in full bloom (not merely one or two), yet not one *Iris stylosa* has made its appearance, though *I. reticulata* (the red-purple one) has been out a fortnight and the dark blue is just coming into flower. One spike of *Kniphofia* (Torch Lily) is out. I do not know the name of this variety, but here it flowers from early spring till autumn, and in a damp, cold border with no sun. After these the mention of *Omphalodes verna*, *Arabis*, etc., seems rather tame.—ALICE MARTINEAU.

Rhododendron dahuricum sempervirens.—Even admitting its great fault—that of scragginess—this *Rhododendron* is well worth growing, because of its early flowering. It gives us small, fine purple flowers at a time when they are extremely welcome. Writing now (January 25th), when none of the other early *Rhododendrons*, such as *nobleanum*, are in bloom, *R. dahuricum sempervirens* is in flower. It is in a bed on the shady side of a hedge which protects it from the gales which sweep across the Galloway hills and penetrate to my garden. It is erect-growing, scraggy, and apt to become bare in its

lower parts, but the branches are crowned with evergreen leaves and little clusters of small deep purple flowers. I prefer the rose-coloured flowers of the type to those of the form referred to here.—DUMFRIES.

Hamamelis arborea.—The statement made by "E. M." (page 51), that this is quite the best of the group may be taken as representing his view, but whether it would be endorsed by the majority is open to question. I should give preference to the Chinese *Hamamelis mollis*, but where opinions vary so much as in the relative beauty of different plants one must not be too egotistical. However, such an authority as Mr. Bean speaks of it as undoubtedly the finest of all known *Witch Hazels*, so that I am not alone in thinking of it in this way. "E. M." also refers to *H. arborea* as being one of the first to bloom. It is certainly in a general way later than *H. mollis*, which is sometimes beautifully in flower by Christmas.—W. T.

Iris reticulata and its diseases.—"S. A." (page 34), I think, rather misses my point. I merely meant that, given clean and healthy bulbs to begin with, and suitable soil, disease could quite conceivably be kept at bay. I am not clear as to whether *Myrosporum adustum* is parasitical to the bulb, or whether it is found under certain conditions of soil and moisture, and attacks the bulb, but in any case it is reasonable to infer that healthy bulbs planted in a favourable situation and with congenial soil would remain healthy. Equally, if the spores are in the soil a good position and exposure would assist in maintaining such bulbs in vigorous health and less liable to be affected by disease. The point appears to me to be interesting, for, beyond question, many bulbs of *Iris reticulata* are annually ruined by being put out, in a manner of speaking, in a haphazard way among more vigorous plants in the bulb borders.—KIRK.

Abies bracteata.—This beautiful Silver Fir, which was given a first-class certificate at the meeting of the Royal Horticultural Society on January 11th, has been long grown in this country. A native of California, it was first discovered by Douglas during his journey in 1830 to 1832. He was, however, not successful in introducing it, that honour falling to William Lobb, who, travelling on behalf of Messrs. Veitch, sent home in 1853 a supply of seeds from which a number of plants was obtained.

tained. *Abies bracteata* is more tender than most of the Silver Firs. For this reason it is more fitted for southern and western districts than for northern localities, while late spring frosts sometimes injure the young growths. The specific name of *bracteata* is derived from the long bracts with which the cones are furnished. The branch shown at the Horticultural Hall from Bury Hill, Dorking, had fifteen cones upon it.

Primula amœna.—This delightful *Primula* is now in full bloom out-of-doors, and has been for some days—a striking illustration of the mildness of the winter. Usually it does not start to bloom until April, for the district is an exposed one. Those readers who have not got it should purchase plants in small pots and plant on a light portion of the rock garden in February or March. It only reaches the height of about 3 inches, but it is well worth growing. Its flowers may be described as light purple, and are given freely when the plant is established.—E. T. ELLIS, *Westwood, Ecclesall, Sheffield.*

The Carpathian Snowflake (*Leucojum vernum carpathicum*).—This is now coming into bloom, its fragrant blossoms, each 1 inch across, on stalks about 1 foot in length, droop gracefully, each petal conspicuously tipped with a bright green spot. It is a more robust variety than *L. vernum*, and is more quickly established, while its value either when cut or in the garden cannot be over-estimated. I use it in a variety of ways, such as growing through long, broad lines of *Aubrietias*, among *Daphne Cneorum* and dwarf Heaths. For nooks in the rock garden associated with *Crocus Imperati*, the whole carpeted with *Saxifraga apiculata*, it would be useful, as all flower about the same time. It should be more often seen in gardens, its cultivation presenting no difficulty. Beautiful as the Snowdrops are, it is difficult to understand why they are so often preferred to this attractive and more ornamental form of the Snowflake. Planted beneath deciduous shrubs, or naturalised in the wild garden, it is quite a success. The bulbs, when established, flower freely.—E. MARKHAM.

Gardening has become a fashionable pursuit, and *The Times* is telling its readers how to grow Peas and Beans. What would John Delane have said of this phase of its activities?

For planting outside later we may sow Peas (Little Marvel) in boxes, in groups of three, at 4 inches apart, and Broad Beans, by twos (Mammoth Longpod). By sowing in groups the plants move with very little check when put out. Seeds which may be sown at once in boxes 3 inches to 4 inches deep are Onion (*Ailsa Craig*), Cauliflower (First Crop or Early London), Cos Lettuce (Dwarf Perfection), Cabbage Lettuces (Ideal and Golden Ball), and Brussels Sprouts (Matchless). These are moved when quite young to boxes at 1½ inches apart and later to a cold frame. Potatoes for planting in February may be set on end in a box and put in a greenhouse to sprout. Leeks (Prizetaker and The Lyon) and Celery (Solid White) may be sown at the end of January.

Mustard and Cress, the reader is told, may also be sown every week in a box. The *Morning Post* now has gardening articles in the same large type. The *Daily Mail* has evolved the common Carrot into a thing 4 feet long, but I am not a believer in evolution, and I have sent to Paris for seed of the little chubby Carrot one sees in the markets there. W.

FRUIT.

APRICOTS.

I AM not surprised to read "W.'s" remarks at p. 16 on the failure of Apricots. We certainly fail more with the Apricot than other fruit-trees, and I think in many cases the failure is due to late growth caused by excessive rainfall in the autumn; also by badly-drained or heavy soil. Many years ago, when living in the west-midlands, where stone fruits did well, it was nothing out of the common to see very old Apricot-trees on the gable ends of houses and buildings, often almost close to the chimneys, and in most cases on sloping borders. These trees bore regularly enormous crops. There was scarcely any winter pruning, as, what was done, was done in the growing season to admit sun and air to the fruit. Though often done roughly there was no canker or disease, but frequently far too many fruits. After the fruits were set the trees were given soap-suds and any waste water, but none was given after the crop was cleared. There was no rank growth as one often sees in these trees in rich borders. I think in a great measure the success obtained was brought about by the efficient drainage and abundance of limestone in the soil. The trees made a sturdy growth with a mass of fruit-spurs.

Many years later, in a locality further south, wishing to get similar results, I planted largely, but with indifferent success. I grew the trees in much the same way as the Peach or Nectarine, but I had to depend on worked trees and failed. I then planted on a wall facing west, with a drop of 6 feet to 8 feet on the other side of the wall. The border was largely composed of brick rubbish and chalk mixed with the loam, which was of a light nature. I got good results as regards fruit, and by no means rank growth, but I had losses from canker. To prevent this I lifted the trees every three years and kept the roots near the surface. Much water was needed from June to August, but none was given afterwards. As the trees attained age, and were too large to lift, I had losses. This brings me to the question of stocks, which, as "W." notes, are important. In the earlier days referred to most of the trees were seedlings, this in a large measure accounting for the splendid crops obtained. C. R.

TREATMENT OF OUTDOOR VINE.

I SHALL be much obliged if you will tell me the proper way to treat an outside Vine. It is growing up the house, and has not been pruned or attended to for some years. Last year there was plenty of bunches, but all went mildewed, and never ripened. It is a black Grape and very small. Will you please tell me how the Vine ought to be pruned and the proper time to do it?—E. R. G.

[Assuming the Vine in question has in the past been trained on the usual lines it will contain a series of stems or rods laid out either in a vertical or horizontal fashion, or it may be in the form of a fan. On these rods there will, or should be, spurs situated on either side at intervals throughout their entire length. It is the annual growths which emanate from these spurs which bear fruit when the Vines have proper attention. We therefore strongly suspect that this is where the neglect comes in, and is the reason for the Vine being in its present state. You will not, of course, be able to get the Vine back to its original condition in a season or two, and perhaps not at all, but your efforts should be directed towards attaining that end by cutting back the surplus wood to a point as near to the spurs as possible where young wood is situated,

which should be cut back to one or two buds. The effect of the cutting back may cause latent buds to push on the old spurs, and if such be the case the resulting shoots when next winter arrives should be spurred in or cut back to two buds. The portion projecting beyond the old spurs, or to where the cutting back will now take place, may then be dispensed with. It is a most difficult matter to explain in a reply of this description how, in such a case, the pruning should be carried out. Your best plan would be to get a practical gardener in your locality to do the pruning for you. This, we may add, should be done without further delay, as there is a risk of the Vine "bleeding," or much loss of sap following if it is left till warmer weather sets in. In regard to "starting," this will, when spring comes in, take place naturally. In "Vines and Vine Culture," by A. F. Barron, there is a chapter devoted to the cultivation of Vines on open walls, which you would find helpful. This publication can be obtained from Mrs. A. F. Barron, 13, Sutton Court-road, Chiswick, London, W., post free 5s. 6d.]

OUTDOOR PEACHES.

MANY people in the Midlands and further north have an idea that the Peach can only be grown successfully under glass, but if only a fraction of the labour annually bestowed on indoor Peaches were given to the culture of Peach-trees on suitable walls the results would be surprising. The trees should have a place where they will have a good chance to succeed, and special preparation of the soil is necessary to ensure success. If the soil is close and damp it should be rendered porous by the addition of broken bricks and lime-rubble, and as growth is far more difficult to deal with out of doors than under glass none of the stimulants generally recommended for Peaches under glass should be added to outside borders. In the case of a very poor and light soil a little well-decayed farmyard manure and bone-meal may, with advantage, be applied. Soot and wood-ashes in small proportions do much to render wood growth firm and fruitful, assisted when the trees get into full bearing by liquid manure and mulchings. When systematic pinching and stopping are practised the winter pruning will only consist in the removal of any semi-exhausted wood that may have been overlooked when thinning out the wood after the fruit was gathered. Nothing should be left on a tree which will die back. This winter pruning may advisedly be left till the beginning of March; indeed, the pruning must be guided by the climate of the district. The early blossoming of the Peach is one of the chief causes of failure out of doors, and if the flowering period can be delayed there is a much better chance of success. To this end the trees should be detached from the wall during winter and fixed to stakes or rods 3 feet or more from the wall, this retarding the flowering period for quite a fortnight. F. W. G.

Litford Hall, Oundle.

NOTES AND REPLIES.

Early vinery.—When the young shoots have fairly started, all those which may not be required ought to be rubbed out without delay. Canes which are right at the roots, and, consequently, healthy, will produce shoots much in excess of requirements, and the sooner those which are superfluous are got rid of the better. For a time the night temperature may range in the neighbourhood of 60 degs. with a fall of a degree or two towards morning should the weather be frosty. The shoots ought to be tied down to the wires as soon as

possible, but this should be done by degrees in order to prevent splintering or breaking the brittle young wood. There should be sufficient atmospheric moisture to induce and to maintain cleanliness and progress.—W. McG.

The best Apples.—It is interesting to note the persistent advocacy of the claims of Ribston Pippin in the pages of GARDENING ILLUSTRATED, and it is to be hoped it may lead to largely-increased planting and improved cultivation. Memory goes back to many orchards in the south of England in which were to be found Ribston trees in more or less numbers, and the wonderful difference in the fruit, as the result of good or bad cultivation, was very noticeable. One particular orchard I remember in which were some half-a-dozen standards of medium size as carefully tended as wall-trees which produced clean fruit of large size and splendid quality. There was little or no trouble with the enemies, now, unfortunately, only too prevalent in the shape of canker, American blight, and

asking what quantity of lime should be used, and the obvious answer would be it would depend upon the condition of the land. In no case would half a bushel per rod do any harm to a vegetable or fruit garden. The best time to apply it is when the land is uncropped. There are times when lime can be used as a dressing to check slugs and other insects, or as a dressing for fungus and other soil troubles. The best way of applying it as a dressing to fruit-trees and bushes is either with or without an addition of soot or sulphur. I have used the mixture in certain cases effectually, especially to check the depredations of bud-eating birds upon Pines and bush fruits. The best way of using lime in the fruit garden is to take the slaked lime in a box-barrow on the windward side of the trees and scatter the lime over the trees with a handy shovel. It is best done early in the morning when the trees are damp.—E. H.

Spot in Apples.—This disease is more widely spread and assumes a more virulent

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

A GARDEN SHELTER.

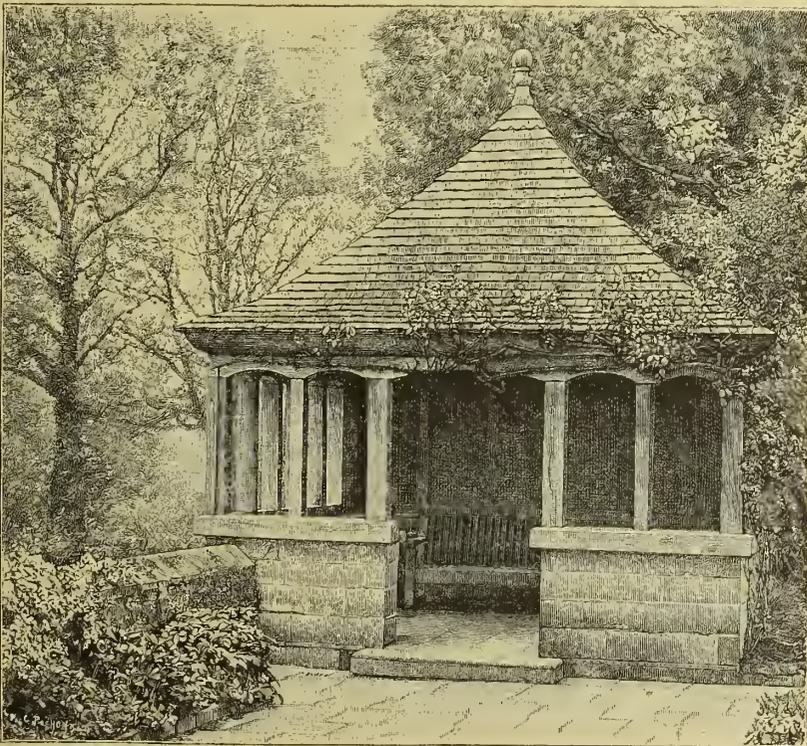

At one time the taste for garden houses was of an elaborate description, but the result did not show well in the end. Such garden houses were, as a rule, neglected, as being too far from the house or in some way useful for any human need. Still, a garden house on a simpler plan may here and there be worth having, and this one is made of sandstone blocks found on the place, with Oak timbers and shingle roof. If I had to do it again I think I should use stone slates, as more enduring and more friendly to Mosses and other plants that grow on such roofs.

W.

TRANSPLANTING CHRISTMAS ROSES.

The end of January is by no means the best time for dividing and transplanting the above-named subjects. Mr. F. W. Gallop, who, at page 62, advocates the practice, would have stood a far better chance of more quickly resuscitating the plants he refers to had he taken in hand the dividing and replanting in September last instead of to-day. Christmas Roses in an "unsatisfactory condition" are the commonplace of many a garden, and will remain so until gardeners realise the peculiar nature of their rooting, and more particularly when and how those roots are formed. Only in this relation can the Christmas Rose be said to be exacting or fastidious. Only, too, can it be said of it that the plant is impatient of removal or of being disturbed when its rooting peculiarities are ignored, and the plants divided and replanted at any time convenient to the planter. The vast majority of gardeners fail to grow this most precious of all hardy winter flowers either from this cause alone or in conjunction with "lifting and potting for flowering at Christmas," as not a few calendar writers recommend. Such plants, when the flowering is over, are often returned to their places, and with very little ceremony. It is but the beginning of the end with many of them, the last state of such plants being worse than the first. In this way our gardens are being depleted—or probably have long since been depleted—of many of the finer tufts, and the best varieties are not easy to obtain.

But very few hardy herbaceous plants, so far as my experience goes, have the peculiar periodical root action of this section of the Hellebore race—the Paeony is almost like circumstanced, and to some extent the Flag or Bearded Irises, if at another season of the year. The majority, happily, are not only vigorous enough, but—and this is the all important matter—sufficiently continuous or perpetual in their rooting to permit of being transplanted with impunity over a considerable period of time. For all such the ordinary methods suffice, while for the minority, which includes the Christmas Rose, special means must be adopted if we are to obtain from them all the good they are capable of giving. To this end an essential is early autumn planting—September, before all else. I say this with the full knowledge that a certain measure of success obtains from planting at other times, and in certain districts till spring. I learnt that way as a boy from my father, and in a county where the Christmas Rose generally did well. Since that time I have studied the root action of the Christmas Rose for my-

A garden shelter.

spot. It can hardly be too strongly enforced that it is only by good and careful cultivation alike below and above ground that the best results can be obtained, and there is no doubt that one is amply rewarded for the attention. Ribston Pippin, Cornish Gilliflower, and Cox's Orange Pippin are our three best Apples from a quality standpoint, and as Cornish Gilliflower is notoriously shy the pride of place must be awarded the Ribston. I have never tasted any Canadian Ribstons quite so good as our best home-grown fruit, but the extra specials in the imported fruit may not have fallen to my lot. The quality of the Newtown is excellent, but it is hardly likely to compete as a home-grown fruit with either Ribston or Cox's.—E. B. S., Hardwick.

Value of lime in the garden.—Do we use enough lime in our gardens? My impression is we do not, especially for opening up and improving clay soils. If we used more lime there would be less disease. We may narrow the question down by

form than in bygone years, and it looks as if spraying will have to be generally, if not universally, adopted if one is to get sound fruit. It was much in evidence in this neighbourhood last year, although some varieties seem much more susceptible to it than others. Last autumn I noticed a nice young standard of Warner's King carrying what appeared from the distance to be a lot of splendid fruit, but closer inspection showed nearly every Apple to be badly spotted, and in this case the disease had struck deeply, and a considerable portion of the Apple had to be cut away before getting to sound flesh. When one remembers that a few years back this Apple had the reputation of being a free, healthy grower unaffected by disease it looks, as above noted, that this black spot is getting much more common. The Blenheim, of which there are some fine old trees in several gardens, were, fortunately, very little affected.—E. B. S., Hardwick.

self and am well satisfied that the fullest measure of success is earliest reached by dividing and planting at the season I advocate. In conjunction with these, deep cultivation is a matter of importance, the roots descending fully 3 feet where the soil permits. In respect of

SOIL, the plant is not greatly fastidious, preferring a medium loam, perhaps, before all else, and a cool, though perfectly drained, bottom. Constant wet at the roots, or a sodden condition of the soil in winter, is fatal. Where such exists perfect drainage is of the first importance—an essential to success. In light, sandy, stony, poorly-cultivated soils the plants are dwarfed. In hot and sandy soils, too, they welcome thin shade, which in cooler-rooting mediums is much less needed. Cold, sunless positions, the product of a wrongly-selected site adjacent to high walls or buildings, are often detrimental to success.

Mr. Gallop rightly touches on what elsewhere I refer to as "the fallacy of the big clump," and nothing is more fatal to good results than transplanting in the clump intact. Why your correspondent recommends "tepid water" for getting the soil away from the roots of this perfectly hardy subject I do not know; it is as needless, though not quite so frivolous, as a "single-jet syringe," which he also advocates.

Big clumps laid on their sides are easily wrenched asunder with a couple of small handforks placed back to back. The operation is also more quickly performed, loss of root is practically nil, washing out unnecessary. Badly conditioned plants may often be wrenched asunder by the hand, their 3-inch to 6-inch long rapidly-decaying roots too often mutely demonstrating the very rough time they have experienced at the hands of the unthinking gardener.

E. H. JENKINS.

SPRING FLOWERS.

In the majority of public and private places the percentage of bulbs planted in the autumn of 1915 was far below the average, and the spring display, so far as they are concerned, will be proportionately trifling. Under such circumstances one will miss the glorious colours of Daffodils, Hyacinths, and Tulips, and be fortunate if able to fall back on batches of good stocky spring-flowering plants easily raised from seed or cuttings, like Wallflowers, Polyanthus, Myosotis, Tufted Pansies, and Double Arabis. If, however, one has to rely mainly on the above for the spring display it must be remembered that, although the raising is an easy matter, considerable attention is necessary to secure a good display, this only being obtained by the aid of nice bushy plants acquired by early sowing or striking, transplanting, and careful lifting. There are now so many different shades in Wallflowers that a certain number of beds can be reserved for this plant either in separate colours or mixed, as the taste of the planter may incline. I never cared for mixing bulbs with Wallflowers (a popular form being the May-flowering *Poeticus* Daffodil with *Vulcan* Wallflower). It was not at all a happy combination; in fact, we have had too much mixing of late years with little discrimination shown in the association of the right families. Similarly Polyanthus are best alone, with an occasional exception of a very dwarf plant like some of the *Aubrietias*. Small beds may be reserved for seedlings, and larger beds for strong clumps, the result of division in spring and keeping over in nursery quarters until planting time. I always think a bed of a really good strain of seedling

Polyanthus a wonderfully pretty feature, and the foliage being rich and luxuriant, and stems and trusses extra strong, a dwarf-flowering carpet is acceptable. To obtain these seedlings in first-class form early sowing and transplanting are absolutely essential.

Tufted Pansies, with care and attention, will last in flower the greater part of the summer. Occasional spaces may be left at planting time for the insertion of a summer-flowering plant like *Fuchsia* or *Heliotrope*. It is in association with trailing plants like *Myosotis* and some of the *Silenes* that the Tulips and late-flowering Hyacinths will be most missed, but substitutes will doubtless be found. Small clumps of the double-white *Arabis*, for instance, that in good soil grows very strongly, would be acceptable for breaking the otherwise flat appearance of the beds.

In places where the opportunity offers for naturalising bulbs, and this may be done even on a small scale, the display and the material for cutting will be very welcome if there are but few bulb inmates of flower-beds from autumn planting. Where one has no wide expanse to deal with, odd corners, nooks, and bits of rough grass, or portions of ground under a standard Apple or Pear, can be utilised for Daffodils in variety.

E. B. S.

Hardwick.

NOTES AND REPLIES.

Antirrhinums.—The value of these, especially the intermediate varieties, is now generally recognised. The present is the time to sow the seed and raise it in gentle warmth. Pans or boxes, according to the number of plants required, are the best receptacles in which to sow the seed. These should be filled with light, rich soil and the surface made firm and level. The seeds being small, a slight covering of fine sandy soil suffices. To avoid disturbing the seed the soil should be well watered before sowing. Shading with paper hastens germination and prevents the undue drying of the surface. A position where an abundance of light can be had is necessary to prevent the plants becoming drawn. As soon as the seedlings are strong enough they are pricked out into a frame. Varieties are numerous, and, as a rule, come fairly true. The most attractive of these are *Fire King*, *Orange King*, *Coral Red*, *Bonfire*, *Cloth of Gold*, *Pure White*, *Carmine Pink*, and *Rosy Queen*. *Nelrose* proved a great acquisition last year and will be grown again this season. *Golden Chamois* and *Crimson and Gold* are two tall varieties which are very effective when used in mixed borders.

Michaux's Bellflower (*Michauxia campanuloides*).—This fine Bellflower does not meet with the attention which it merits, and now, when the seed-list is being made up, a packet of seed of *M. campanuloides* might very well be included. The seeds germinate well under greenhouse temperature, and the seedlings should be handled as soon as possible. In July plant them out in rich soil in a sheltered exposure, and encourage growth as much as possible. During late autumn transfer them to their flowering quarters, and during the following season a rich display of white, pink, and pale-blue spikes, almost 6 feet in height, will follow. After flowering, the majority of the plants will succumb. It is advisable, therefore, to raise a batch of seedlings annually.—KIRK.

Tellima grandiflora.—This will grow on shady banks in rich soil, and is thus suited to places where many things would not survive. It grows from 1 foot to 3 feet high, has leaves something like those of a *Heuchera*, and long racemes bearing greenish-yellow flowers, which are often tinted with rose.—S. A.

INDOOR PLANTS.

CASSIA CORYMBOSA.

This, a native of Buenos Ayres, is worthy of outdoor cultivation wherever possible. It grows some 15 feet to 20 feet in height and in the early and late autumn produces corymbs of golden-yellow flowers which are so numerous as to nearly conceal the plant when at their best. It requires to be planted against the hottest wall and grown in rich, well-drained soil, as this treatment will tend to develop it to the greatest advantage. It should be planted deeper than most shrubs in order to minimise the effects of winter frosts. If this is carefully done and if it is afforded some slight protection during the winter months it may succeed in many places where it has hitherto failed, but in which it would, owing to the rich colour of the flowers, prove a valuable addition to a garden.

R. H. BEAMISH.

FLOWERING PLANTS FOR THE GREENHOUSE.

I HAVE a large greenhouse in which in the spring I have in flower *Primulas*, *Cyclamens*, *Deutzias*, *Genistas*, *Azaleas*, and *Arum Lilies*; in the summer, *Begonias*, *Gloxinias*, and *Pelargoniums*; in the autumn, *Chrysanthemums*, *Cinerarias*, *Coleus*, with fine-leaved plants as *Dracenas* and *Ferns*; in the winter, *Hyacinths*, *Tulips*, and *Daffodils*. I want more plants for the hall and the house, and will be glad if you can kindly help me by adding to the list and giving some hints as to their culture.—SINGLETON, *Bradfield*.

[In addition to the

SPRING-FLOWERING SUBJECTS mentioned by you, quite a long list of flowering plants suitable for the greenhouse might be named, among the best being *Acacias* of different sorts, especially *A. armata*, *A. Drummondii*, *A. hastulata*, *A. lineata*, and *A. ovata*. All of these have flowers of some shade of yellow. They may all be stood outside during the summer. *Alonsoa incisifolia*, an easily-grown, half-shrubby plant, bears spikes of orange-red flowers over a lengthened period. It is easily propagated in spring by seeds or cuttings. Some of the *Auriculas* are very expensive, but the alpine varieties are comparatively cheap and very effective in the greenhouse. Of *Boronias*—a class of hard-wooded plants that need much the same treatment as *Indian Azaleas*—the best are *Boronia megastigma*, with yellowish-brown, deliciously-fragrant blossoms, and *B. heterophylla*, whose flowers are carmine in colour. *Carnations* of the perpetual-flowering class are so generally grown that they must on no account be omitted. *Camellias* are well-known flowering shrubs for the greenhouse. Sown in summer, the herbaceous *Calceolarias* make a goodly show in spring. Beside the ordinary forms the graceful habited *C. Clibrani* can be recommended. *Clivia miniata* forms a handsome tuft of dark-green, strap-shaped leaves, from which are pushed up large hemispherical heads of orange-red flowers. *Clarkias* are very showy annuals, which, if sown in the autumn, will flower in the spring. *Coronilla glauca* has bright yellow, Pea-shaped blossoms. *Dielytra spectabilis* (*Bleeding Heart*) is a herbaceous perennial whose drooping, rose-coloured flowers are very effective when it is grown in pots. *Epacris* are Heath-like plants with flowers of different colours. Several Heaths flower in the spring, notably *Erica Spenceriana*, *E. Wilmoreana*, *E. eandidissima*, and *E. persoluta*. *Hippeastrums* (*Amaryllis*) are bulbous plants with large, showy Lily-like blossoms of different colours. If good clumps of Lily of the Valley are potted up the flowers will come on nicely

in the greenhouse. A great many Primulas are available for greenhouse decoration in spring, as apart from the Chinese Primula, there are *P. obconica* of various colours, *P. malacoides* lilac, *P. Kewensis* (pale yellow), and *P. floribunda* (rich yellow). All these can be raised from seeds sown in the spring. Rhododendrons of the greenhouse kinds are very showy when at their best. They should be given the same treatment as Azaleas. *Richardia Elliottiana* (the golden-flowered Calla) passes the

very pretty. *Agapanthus umbellatus* produces its heads of blue flowers towards the end of summer. The small tubers of *Achimenes* should be kept nearly dry in the winter and shaken clear of the old soil, and if repotted in early spring they will grow away freely and produce a large quantity of showy blossoms in summer.

The dwarfier varieties of Cannas are very effective when in bloom. *Celosia plumosa* is remarkable for its feathery

white flowers. Fuchsias, too, should be largely grown, while the fragrant blossoms of *Heliotrope* render it a universal favourite.

There are now several desirable species of Impatiens, of which *I. Holsti* (vermillion), and *I. Oliveri* (mauve) are among the best. The Balsam (*I. Balsamea*) is also a very beautiful tender annual. Lantanas are little shrubby plants, whose heads of blossoms, suggestive of a Verbena, are of different colours.

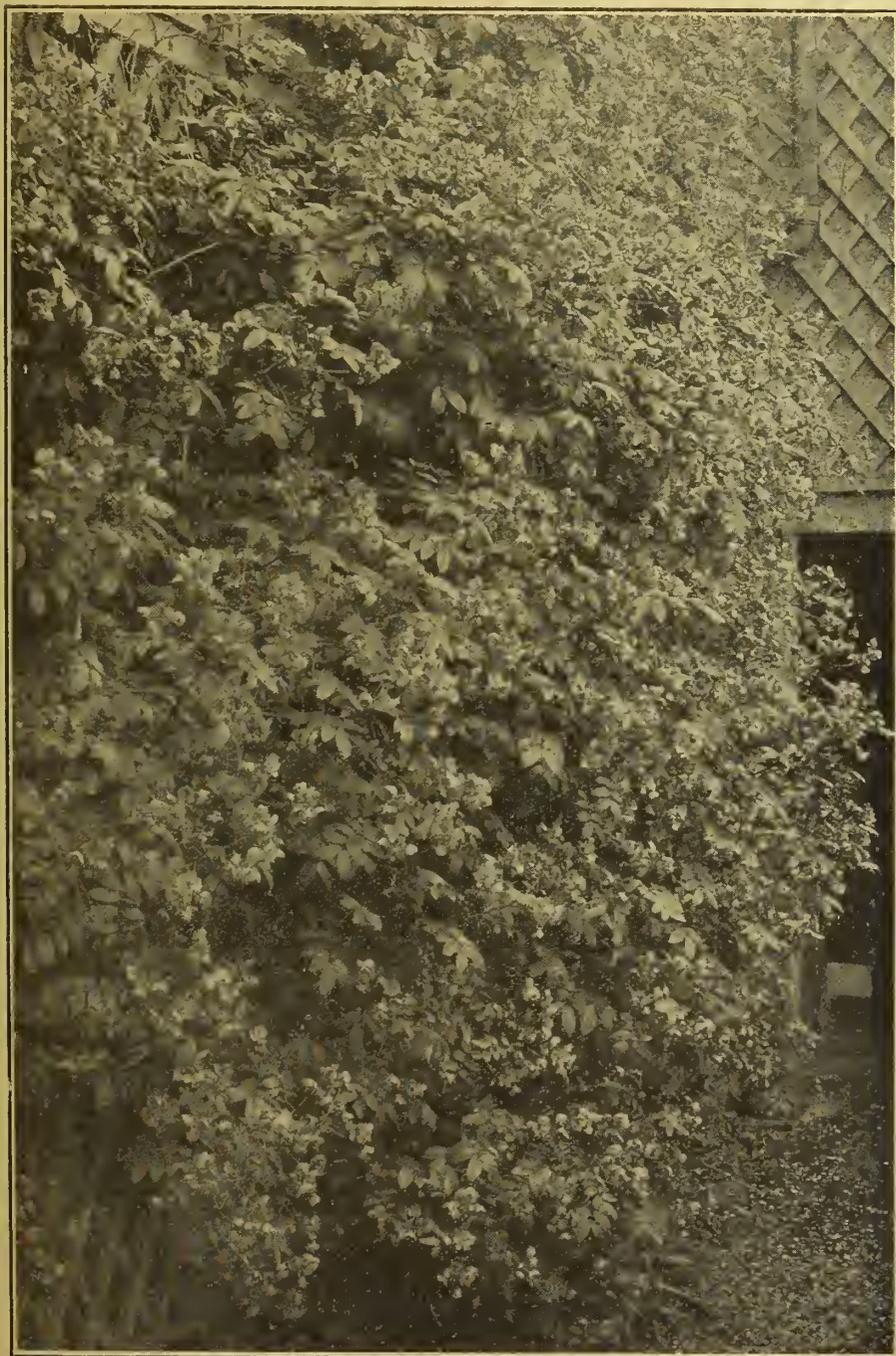

The long, silvery trumpets of *Lilium longiflorum* are much appreciated for greenhouse decoration. The bulbs should be potted early in the year and kept just safe from frost. Other Lilies available for the same purpose are *L. auratum* and *L. testaceum*. Several forms of Marguerite are now in cultivation, the most generally grown being the double-flowered Mrs. F. Sander. The Nemesias are charming annuals for pot culture. Three plants in a 5-inch pot will form delightful little specimens. Seed should be sown in spring. Petunias are well known and easily-grown, free-flowering plants, that may be increased either by seeds or cuttings in spring. Phyllocaeti are among the showiest of all the Cactus family. Except when in bloom they need full exposure to the sun. *Rhodauthe Manglesi* is a pretty everlasting annual with pink or white blossoms. Six to eight plants will suffice for a 5-inch pot. The blue flowers of *Statice profusa* last long in beauty. The flowers of the *Streptocarpus* are somewhat like small forms of *Gloxinia*, the cultural requirements of the two being about the same. Seed of *Torenia*s, pretty tender annuals with purple and yellow flowers, should be sown in spring.

All of the autumn-flowering Bouvardias are pretty, free-flowering, little shrubs with neat clusters of tubular blossoms of different colours, easily increased from cuttings of the young shoots in spring like Fuchsias. Some of the shrubby Begonias, such as *B. semperflorens*, *B. Weltoniensis*, and *B. Corbeille de Feu*, as well as the earliest of what are regarded as winter-flowering varieties, bloom in the autumn.

HEATHS.—Of the greenhouse Heaths that flower in the autumn *E. gracilis* is the best, its rosy-purple blossoms being borne in great profusion. There is a white variety—*navalis*. If *Lilium speciosum* is grown out-of-doors till the buds are on the point of expanding the flowers will come in nicely during September. *Lilium nepalense* and *sulphureum* flower later. Nerines are a class of remarkably showy bulbs whose flowers vary from white to crimson. The shades of scarlet and orange are particularly bright. They remain dormant in summer, during which time they need to be well exposed to the sun and kept quite dry. *Salvias* are plants of easy growth, that may be increased either by seeds or cuttings in spring. The best are *Salvia splendens* (scarlet), *S. azurea grandiflora* (light blue), and *S. leucantha* (white with mauve hairs). *Vallota purpurea*, a bulbous plant, has bright red, Lily-like flowers.

There is now a great number of varieties of *Veronica speciosa*, all of which will flower freely when grown as neat little bushes. They may be stood out-of-doors in the summer and taken under cover before frosts set in.

WINTER FLOWERING.—*Agathæa cœlestis* is a little bushy plant with Daisy-like flowers of a pale-blue colour. To obtain blooms in winter it should not be allowed to flower during the summer. Seeds or cuttings. The winter-flowering Begonias

Part of a plant of *Cassia corymbosa* in the open air at Ashbourne, Glounthaune, Co. Cork.

winter in a dormant state, when it should be kept dry and flowers in the spring. *Schizanthus* must be sown in autumn for spring and in spring for summer flowering.

Many shrubs are of great value in the greenhouse, particularly Lilacs, Azaleas, Double-flowered Cherry, *Andromeda floribunda*, and others. *Spiræa japonica* is much used for greenhouse decoration, the feathery plumes being much admired. The pink form, Queen Alexandra, is also

heads of blossoms of varying, but very pronounced, shades of colour. Seed should be sown in spring and the plants grown on freely. *Crassula coccinea*, a South African succulent, grows a little over a foot high and bears clusters of tubular-shaped, bright-crimson flowers. *Diplacus glutinosus* is a neat little shrub with flowers like a *Mimulus*, but buff in colour. A variety with orange flowers is known as Sunbeam. *Francoa ramosa* (Bridal Wreath) bears long spikes of pretty

are now a very important race. From the crosses between *B. socotrana* and the tuberous-rooted varieties we have flowers of various colours. Besides these there is the popular *Gloire de Lorraine*, represented by several forms. All of these should, after flowering, be kept somewhat drier, but not parched up, for a month or so. Then, with brighter weather and increased moisture, young shoots will be pushed out, which may be taken as cuttings. *Browallia viscosa* forms a freely-branched plant a foot or more in height. The flowers are of a rich blue with a white centre. It is of easy culture. Seeds or cuttings. *Chorizemas* are hard-wooded shrubs with harsh, somewhat Holly-like leaves and orange-coloured, Pea-shaped blossoms. They need sandy peat and firm potting. *Erlangea tomentosa* is an *Ageratum*-like plant, with pale lilac-coloured blossoms. Very easy to grow. A particularly good *Eupatorium* is *E. petiolare*. It grows from 18 inches to a yard high, and bears double, Daisy-like flowers of a blush tint. Strikes very easily from cuttings in the spring.

The best winter-flowering greenhouse Heath is *Erica byemalis*. Of this there is also a white variety. *Jacobinia chryso-stephana* bears its tubular-shaped, orange-yellow blossoms in terminal crowns. *Lindenbergia grandiflora* is something like a Giant Musk, its golden-yellow blossoms being borne throughout the winter.

The orange-yellow flowers of *Linum trigynum* form a bright and cheerful mid-winter feature. *Sparmannia africana* will form quite a big bush, while on the other hand it will flower well in 5-inch or 6-inch pots if well exposed to the sun during the latter part of July and in August. The brush-like crowd of stamens, purple and gold in colour, is very striking.

As some fine-foliaged plants are included in the list the following additions may be made:—*Asparagus plumosus nanus*, *Asparagus Sprengeri*, *Aralia Sieboldi*, *Araucaria excelsa*, *Aspidistra*, *Coprosma Baueriana variegata*, *Eurya latifolia variegata*, *Grevillea robusta*, and *Ophiopogon spicatum variegatum*.]

NOTES AND REPLIES.

Stapelia variegata.—Can you tell me anything about the cultivation of *Stapelia variegata*? What temperature is required?—W. M. CROWFOOT.

[*Stapelia variegata*, of which *S. Curtisii* is a synonym, is, like all the members of the genus, a native of South Africa. It needs a soil mainly composed of good loam lightened by an admixture of broken brick rubble and silver sand. The pots, too, must be effectually drained. The night temperature during the winter should fall little, if any, below 50 degs. With this consideration it may throughout the winter be regarded as a greenhouse plant. A shelf near the glass in a light, sunny, airy structure is the best place for it at all seasons. During the growing period it must be kept moderately watered, but in the winter very little should be given. Do not give stimulants at any time.]

Tulip Artus under glass.—When the earliest Tulips, such as the Van Thol family, are over, a good and useful variety may be found in *Artus*. Taller than the Van Thols, this variety is more striking and effective, its brick-red colour being very noticeable when grouped. *Artus* forces readily, and where a quantity of bulbs can be boxed the blooms are appreciated early in January for cutting.—KIRK.

Hydrangea hortensis.—Young plants struck from cuttings last season have been shifted into larger-sized pots, in which they will flower and be put into the early vinery. A number of plants raised from cuttings two years since has also been shaken out and reported. These, when in flower, will be most useful for filling bowls and other receptacles for room decoration.

GARDEN FOOD.

MILL DUST AND HEALTH.

I HAVE NOW the pleasure of eating really good oatmeal, that is, oatmeal groats prepared in Scotland. They are nearly the full size of the grain, divested of its chaff, and entirely free of mill dust. Oatmeal is the most wholesome food grown in the British Isles, and it deserves careful attention at our hands. It is often spoiled in cooking, and, further, it is often supplied in the form of dust. Groats or pin-head oatmeal, as supplied by Scotch or Irish millers, is the best form in which to use this excellent food. I get mine from Coopers, of Annan. I mention them because it is not easy to get this form of oatmeal.

Most of our cereal foods are spoiled by being reduced to cereal dust. In this form it does harm to the human economy, and the grains are better taken in their natural form. Reducing any of them to dust brings them to simple, starchy, pappy foods, and in this way they have a bad effect on child or man. This reducing of such foods to fine dust also leads to adulteration, and if not that to the destruction of their fine natural flavours, as the dust absorbs other odours from the air and its surroundings. Our teeth were not given us for nothing, and if we grind and chew well all our best food we find good and useful work for our teeth. It is not, however, easy to masticate properly these foods in the pappy state, and by eating them without chewing we injure ourselves. Then, again, the juices of the mouth and stomach cannot well permeate these masses of sloppy food, and some indigestion may result from their use. The groats should be partially cooked over-night and left in the warm oven or on the stove until morning, when they are soon prepared for the table. I generally have them for breakfast, served with a little honey and water in a cup. W.

SOME SIMPLE DISHES.

HOT SLAW.—Shred the Cabbage finely, as for cold slaw or Cabbage salad, boil rapidly in salted water until tender, and drain thoroughly. Make, meanwhile, a sauce of one tablespoonful of butter, half a teaspoonful of salt, a little pepper and cayenne, and, if it is liked sharp, as much as a cupful of vinegar. The vinegar must be a good one, however, either malt or cider, for the cheap brands contain acetic acid and are very harmful. Pour the sauce over the Cabbage, put the cover on the saucepan, and let it stand on the side of the range for five minutes, when sauce and Cabbage should be perfectly blended.

CARROTS AND TURNIPS.—Do not serve Carrots so hard and raw that it would make a horse hungry to look at them. Young Carrots are delicious served whole. Boil them in salted water, and then drop them into a saucepan, with a lump of butter, some pepper, salt, and a pinch of brown sugar, and sauté them for a few minutes before serving. Turnips should be treated in the same way. Some people prefer to do without the sugar, but if the taste of it is almost imperceptible it seems to bring out the flavour of the vegetable.

CAULIFLOWER AND TOMATO SAUCE.—Soak a Cauliflower in cold water for an hour and then cook it. Take two or three fresh Tomatoes, or half an ordinary-sized can of Tomatoes, strain them and bring to a boil. Add Onion juice, salt, and pepper, a tablespoonful of butter and a tablespoonful of flour. Stir until smooth, and let the sauce simmer slowly for five or six minutes until the flour is thoroughly cooked. When the Cauliflower is quite tender, break it into pieces, put into a hot, deep dish, and pour the Tomato sauce over it.

DRIED LIMA BEANS—BOILED.—Soak a cupful overnight in cold water, drain, and cook in boiling salted water until thoroughly soft. There should be practically no water left to pour off when the Beans are cooked, but what there is should go into the stock-pot. Add three-quarters of a cup of cream to the Beans, season with pepper, butter, and salt, and put them back into the saucepan to get thoroughly hot again before serving.

BAKED CABBAGE AND CHEESE.—Boil the Cabbage in two waters, drain thoroughly, and let it get cold. Make a sauce by mixing a table-

spoonful of butter with one of flour, and cooking them together until they bubble, stir in a cupful of milk until thoroughly blended, and season with pepper and salt. Now take a baking dish, butter it well, and sprinkle with pepper and salt. Place in it a layer of the cold Cabbage, pour some of the sauce over it, and sprinkle a heaped tablespoonful of grated cheese on top. Repeat this process till the dish is full, and add a layer of fine bread-crumbs on the top. Bake covered for about half an hour, and then remove the cover until the top is browned. This dish is practically a meal in itself, and makes a most delicious course for a dinner.

CELERY AU JUS.—Remove the coarsest stalks and trim the roots of several heads of Celery, cutting them into pieces 6 inches long, but leaving them still attached to the root. Now make a brown roux with two tablespoonfuls of flour, two of butter, a quarter of a teaspoonful of pepper, and a pinch of Nutmeg. When this is well browned, add two cupfuls of stock, put the Celery in it, cover and stew very quietly for twenty-five minutes. Take out the Celery and arrange it neatly on a dish, straining the gravy and pouring it over and around.—HON. MRS. GUEST, in *Daily Chronicle*.

NOTES AND REPLIES.

Celery worth having.—My Celery this year is coarse and almost useless. Have readers any notion of a hardy, above all crisp, eating Celery? Mine is far too large, loose in habit, useless for the cook, and worse still to eat in salad. Also it is apt to decay in the centre. There is, I hope, some kind worth having?—W.

Apples in salads.—It is a mistake to give up the idea of having good winter salads, and among the things that go to make them a well-flavoured Apple is a help. My salad is now of Lamb's Lettuce, bits of good Celery, and slices of Newtown Pippin Apple mixed. Any first-rate and not mawkish or over-sweet Apple will do as well, and a very little of anything like Chervil may be sprinkled in.—W.

Barley in the home.—Just now everyone is interested in economy in cooking, so I think perhaps some may be interested to know of the uses to which I put Barley. Long before the war Barley-water was the beverage in this house. It was made of a wineglassful of Pearl Barley well washed. Put into an enamelled saucepan in cold water, boil it ten minutes, put the peel of half a lemon into a large jug with 1 oz. candy sugar, tie muslin over the jug, strain the juice of the half lemon through this, then strain the Barley-water into the jug. We occasionally made a pudding from this Barley. Leaving it in the saucepan, you add Sultanas and a little water, boil for an hour, pour into a pie-dish, add milk and a little sugar, and bake slowly for two or three hours. Another way is to substitute grated cheese, pepper, and salt for former ingredients. When we did not use the Barley thus we gave it to the chickens, but since the war the chickens go without and we make savouries as well as puddings. Put the Barley into a casserole, with a liberal allowance of Tomato sauce, salt to taste, and a teacupful or more of water; stew several hours. Yet another dish.—Substitute in place of Tomato sauce chopped Onion, Apple, a few bones or bits of meat, curry powder, teaspoonful of vinegar and sugar. Both these are good supper dishes and economical, as the Barley does first for Barley-water, secondly for supper dishes.—A Suffolk lady writing to the *East Anglian Daily Times*.

Bottled fruits.—Bottled fruits—Gooseberries, Plums, and Blackberries—are just now (late January), with Apples getting a bit over and Rhubarb hardly ready, very acceptable. They were treated in the simplest manner—just put into wide-mouthed glass jars, which were placed in the oven until thoroughly warmed through, then filled up with boiling water and fastened down with some grease-proof paper and a starch plaster. The Blackberries are specially good. I was fortunate in getting extra fine fruit, free from dust, and thoroughly ripe.—E. B. S., *Hardwick*.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

THE WATER GARDEN.

The water garden has become a most popular adjunct to the garden proper, and often as much interest and enthusiasm are centred round a small artificially-constructed pond accommodating only a few water plants as over a larger expanse of water offering greater possibilities. To construct a water garden on a site where the environs are altogether out of sympathy has only to be attempted to realise the difficulty, unless, of course, quite a formal one is decided on, then it is only a matter of following out the details of

The artificial appearance of a dam is always troublesome to disguise, and when bricks and concrete are used in its construction no part of the materials should be visible. This can usually be overcome by heaping up soil in front of the dam as well as behind, and by the judicious planting of shrubs and plants on the dam and groups of water plants in front of it the formal outline can be obliterated. The back of a dam offers much scope for rock-work, and when large boulders of rock are placed in natural positions a very bold effect is produced and a home made for an endless variety of handsome, fine-foliaged and flowering plants. The result is that in place of a long mound of soil faced nearest the water with a brick wall is a

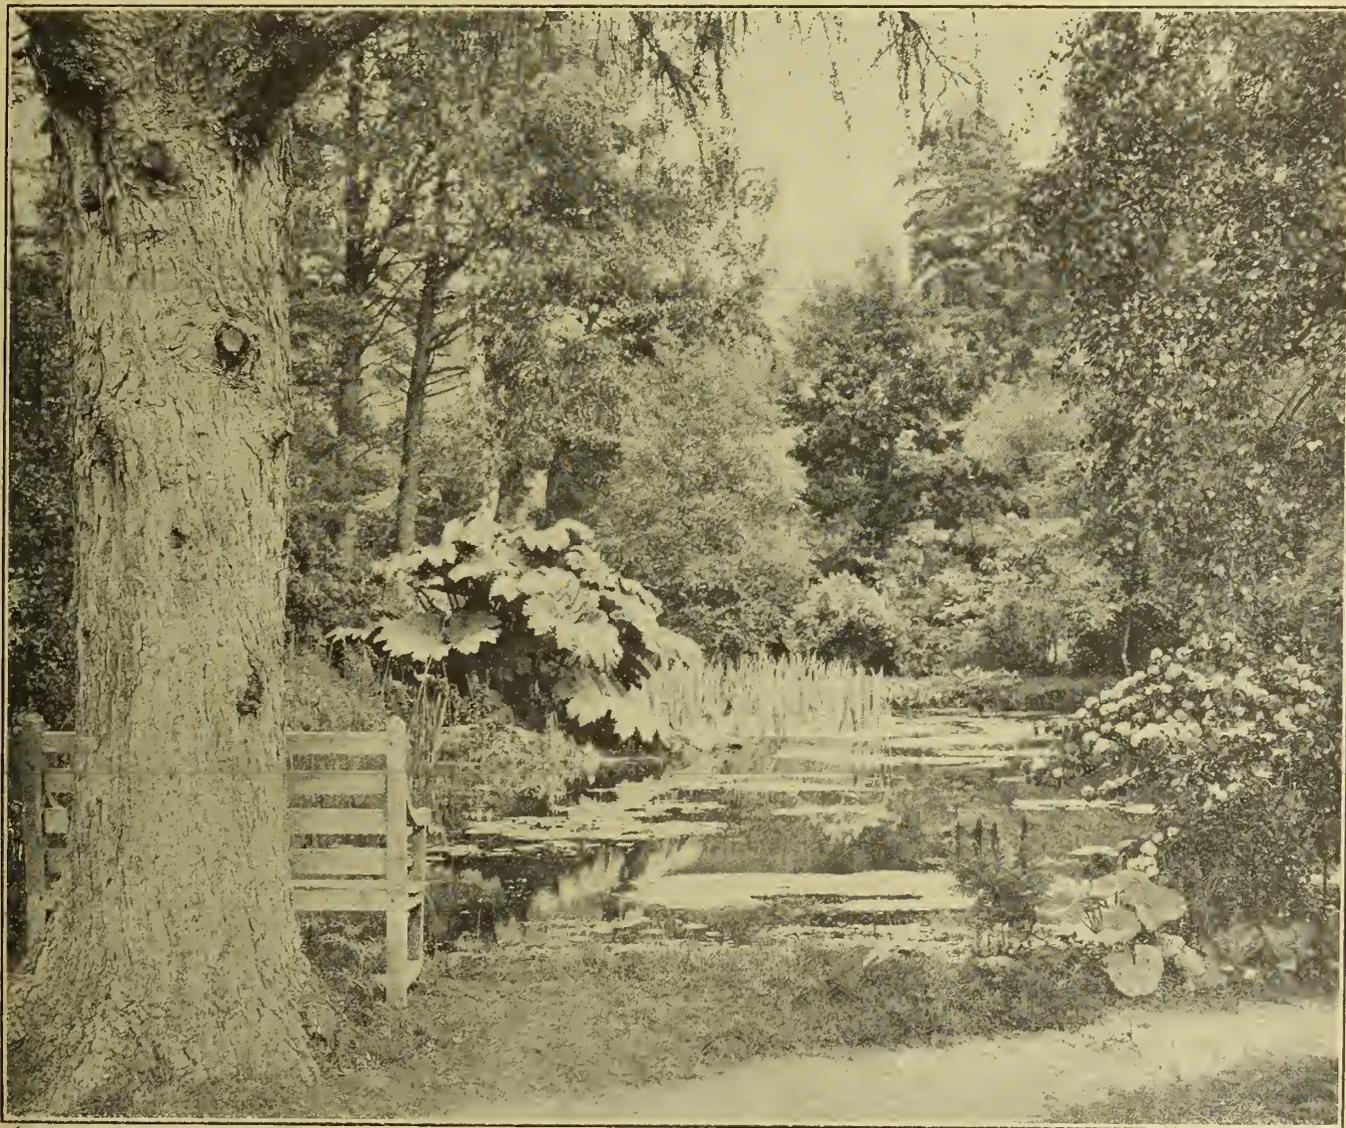

pseudo acorus, though common, is beautiful, *Pontederia cordata* likes shallow water, *Calla æthiopica* planted in a foot of water in a sunny position flowers freely in early summer, as also does *Sagittaria sagittifolia*, the double form of which is handsome and likes full sun.

T. B. FIELD.

Wych Cross Place, Forest Row, Sussex.

NOTES AND REPLIES.

Erysimum pumilum.—The dwarf *Erysimum* is one of the most appreciated of the yellow rock plants of spring. In the rock garden or in the moraine it affords, when in bloom, a bright patch of colour. It is dwarfier than *E. pulchellum* and has not

Part of the water garden at Wych Cross Place, Forest Row, Sussex.

some devised plan, but if the idea is to imitate Nature, then it entails much observation and tact in carrying it out.

The illustration is a portion of a water garden made some four years ago, the existing surroundings being all that could be desired when the site was chosen. It is part of a wooded dell with a stream of clear water running through it, and by making a dam across at a place where the stream was most sluggish a fair-sized pool was obtained varying in depth to 5 feet in the deepest part. The sides of the dell now forming the boundary of the pond were left quite natural, no shaping being done to them, a detail of importance under such circumstances, as the natural outline of the banks could not be improved upon.

site made interesting with waterside subjects thriving with very little attention.

The irregular path seen in the extreme front of the illustration continues over a dam similarly treated, and *Viburnum plicatum* can be seen in full flower. *Spiræa Lindleyana* is another beautiful flowering shrub for the purpose, revelling in the moisture. Japanese Maples have been very successful in sunny, sheltered positions, and groups of Sweet Briar and some of the strongest-growing Penzance Briars, such as Meg Merillees, Jeannie Deans, Amy Robsart, and Anne of Gierstein, are most attractive planted so as to reflect in the water. Amongst water plants the following were easy to establish, soon forming nice groups. Iris

the loose-flowered style of this, while the blooms are brighter and more numerous. The flowers open a pale sulphur, but in time they take on a deeper and brighter hue. It is only a few inches high and forms a spreading carpet of green, which in spring is almost hidden by the yellow Wallflower-like blooms. It can be easily raised from seeds or propagated from cuttings.—S. A.

New Index and Binding Cases for completed Volume.—The Index to Volume XXXVII. of GARDENING ILLUSTRATED is now ready (price 3d., post free 3½d.). The Binding Case for the same volume is also available (price 1s. 6d., by post 1s. 9d.). The Index and Binding Case can be obtained from any newsagent, or from the Publisher, 63, Lincoln's Inn Fields, London, W.C. If ordered together, the price of the Index and Binding Case is 2s., post free.

TREES AND SHRUBS.

NANDINA DOMESTICA.

I HAVE read with much interest the article on this beautiful shrub in the issue of January 29th (p. 53). The description therein given is quite in accord with what I saw of the plant at Pau, in France, when doing a tour amidst the Pyrenees about Easter a few years back. It was in beautiful condition there, being planted near to, and within the shelter of, the Casino in the public park, facing nearly due south, and fully exposed to the sun. It is this full exposure to the warmth of the sun's rays, and the consequent thorough ripening of the wood, that renders it able to withstand a fairly sharp snap of frost. The colour of the foliage there was lovely, the habit rather stiff, being nearly erect. The group, or it might have been originally one plant only, was well furnished with foliage to the ground, and would be about 7 feet in height. In "Japanese Gardens" Mrs. Basil Taylor gives her impression of this *Nandina* as she saw it in Japan. This lady speaks of the "reddening berries of the *Nandina*," and "*Nandina domestica*, known (along with several other plants) as the 'Holly of the Orient,' has brilliant red fruit." I am afraid it is hopeless to expect to see this description applied to it in this country. Mr. James H. Veitch, in "A Traveller's Notes," states that it is one of the plants upon which the Japanese experiment in their dwarfing practices; also that "it is a very common plant in the nurseries, growing from 6 feet to 7 feet high, bearing a profusion of red berries." Later on, and when at Melbourne, in Australia, Mr. Veitch noted it about 5 feet high and as much through. In Japan he observed a variety with white berries, and Mrs. Basil Taylor describes another with yellow berries. These might, however, be the same form. When I used to grow it here I plunged it outside during the summer, being afraid to risk full exposure.

JAMES HUDSON.

Gunnersbury House, Acton, W.

NOTES AND REPLIES.

Cupressus macrocarpa.—I put out several thousands every season, raising them from seed sown about the end of March, and planting them out in their permanent quarters as one-year seedlings, when a large proportion of them are about a foot in height. They are planted out any time between October and April, and I cannot say that I notice very much difference in the results. I have planted this species in several parts of the country, and I find that where the land is rich and the situation is sheltered the trees grow up so fast that they have a difficulty in maintaining an erect position without the aid of stakes. On the other hand, where the plants are used on bare, exposed, and poor chalk on the South Downs, the growth is much slower and the trees are much more resistant to wind; in fact, under these circumstances I do not find that this species has a greater tendency to be swayed or blown over than any other species that I have used. Under the conditions of soil and exposure that the South Downs offer, I find that no other species of tree grows or promises so well as *Cupressus macrocarpa*.—PROFESSOR SOMERVILLE in *The Garden*.

The Mexican Orange-flower (*Choisya ternata*).—This is to be found in almost every garden where flowering shrubs are favoured. Nor is this to be wondered at. When in bloom its trusses of white, sweetly-scented flowers always attract at-

tention. This shrub is of a symmetrical habit, and, unlike many others, does not encroach unduly. This circumstance makes it peculiarly valuable for those who wish to grow the choicer shrubs and who have not too much space at their disposal, and, on the other hand, it can be effectively used by those who wish to margin taller and more robust shrubs with one of a dwarfer nature. The foliage, too, is attractive at all times of the year—never more so than in the depth of winter. In the matter of soil the Mexican Orange-flower is not exacting. Certainly it succeeds better when the staple is of a peaty nature, but peat is not absolutely necessary. A deep, dark, loamy soil, such as is to be found in many old gardens, will suit well, or the average mould of the shrubbery enriched with plenty of half-decayed leaves will be found sufficient. The shrub does not object to partial shade if it gets a fair proportion of sun at some period of the day, and, when established, it gives but little trouble afterwards. One place *C. ternata* objects to, and that is at the foot of a south wall, fully exposed to the sun in rather shallow but otherwise suitable soil. With a view to making a specially fine piece a plant was put out in such a position. From the beginning it was a disappointment, it made little or no progress, but on being lifted and moved to a cooler spot it speedily took hold and grew within a few years into an almost perfect specimen. *C. ternata* is easily propagated by means of layers—more easily by cuttings, although cuttings take a longer time to make plants.—K. BRIGHT.

VEGETABLES.

SALT IN THE GARDEN.

I HAVE some garden salt for an *Asparagus* bed I am making. How much should I use? I have more salt than I need for the *Asparagus*. Can I use it for other vegetables? If so, for which? When should I put it on the ground? Is it actually harmful to anything in the vegetable garden?—A. H.

[Salt, if applied at the proper time, is a safe and fairly good stimulant for *Asparagus*. It must not, however, be used on newly-planted beds, as it then exercises an adverse effect on the root system of the plants or crowns. You must therefore wait until the crowns become properly established, which, if growth is satisfactory during the coming summer, will be next spring. The time to apply the first dressing is about a fortnight or three weeks before the first lot of heads may be expected to appear above ground, or about the middle of March. A further dressing may be given early in May, and at intervals during the summer, but not afterwards. The quantity to use on the first occasion would be about 8 oz. per square yard. Many apply twice and thrice this quantity, but it is better to err on the safe side and apply too little than too much. On subsequent occasions use about half of the above-named quantity. If you wish to grow really fine *Asparagus* you would find fish guano superior in every way to salt. Other crops for which a little salt is beneficial are Beet, Parsnips, Carrots, Onions, and Seakale. For the first four sufficient of the salt may be sprinkled on the surface of the soil to whiten it when digging is about to take place. In regard to Onions it can be used in conjunction with well-rotted manure. A slight quantity sprinkled between the rows of Beet after the plants have been thinned and are growing freely will stimulate growth and tide them over a season of drought. For Seakale it is best used while growth is being made, and may therefore be applied at intervals during

the summer between the rows of plants. Salt is also a good thing to sprinkle on and mix with the soil when digging and pulverising it in readiness for the moulding of Celery.]

NOTES AND REPLIES.

Grubs in Brussels Sprouts.—I should be very much obliged if you would kindly give me some advice about the treatment of Brussels Sprouts. For some four years my plants have been troubled with a small green caterpillar. It is not visible when the vegetable is raw and cannot be removed by washing, but comes out during cooking. It is green when alive, and white when cooked. Ought all the plants to be destroyed, and how should the soil be treated? The blight does not appear, so far, to have spread to the other green vegetables. It is in the heart of the Sprouts.—MOLLINGTON.

[We have very closely examined the Brussels Sprouts submitted and fail to find the slightest sign of insect life in them, let alone grubs like the specimen sent. Under the circumstances the only thing we can advise you to do if you are still certain these grubs are secreted in the Sprouts is, when preparing them for cooking, to remove more of the outer leaves than usual and then to immerse them for half-an-hour in salt and water to which a little vinegar has been added. If sufficient salt is used the grubs will not be long in vacating the Sprouts and come to the surface of the water. If well washed before the Sprouts are put into the saucepan to cook the flavour will in no wise be impaired. Destroying the plants would be of no avail, but after they cease to yield sprouts it would be as well, when preparing the site for the succeeding crop, to dress the soil with one of the soil fumigants which are from time to time mentioned in our advertising columns. If it can be so arranged no kind of Brassica should be grown on the same plot for the next season or two. By adopting these suggestions the pest, whatever it may be, should be got rid of.]

Broad Beans, black-fly on.—Would you kindly tell me if there are any effective preventive measures against the Bean-aphis? I lost nearly all my Broad Beans last year, and so did a good many growers in the neighbourhood. I am only trying early—i.e., November and January—sowings, and dressed the plots well with Vaporite. Is it known when these pests breed, and is there any means of destroying them before they mature? For the present I am only using artificial manures, as the garden abounds in pests of all kinds, which is certainly partly due to a lavish use of stable-manure for a great many years. I am told it is even worse in a garden very near, which was made on a common less than a year ago.—R. N. F.

[As soon as you can see any of the fly on the Beans syringe the plants with paraffin emulsion or Quassia extract. A friend of ours uses X.L. All insecticide and finds it efficacious. Another way is to watch the plants closely, and as soon as the parasite is noticed to top the Beans, placing the shoots in baskets and at once burning them. An early start in topping may save trouble later, and it may be done while the plants are in flower.]

Celery.—A small sowing will be made early in the present month for the earliest supply. The plants from this sowing should be ready for use during August and September. I sow the seeds thinly in small, well-drained pans filled with finely-sifted loam, leaf-mould, and manure from a spent Mushroom bed, adding sufficient coarse sand to keep the soil open. Water the soil carefully through a fine rose and stand the pans in a forcing-house where a temperature of 55 degs. is maintained at night. Directly the seedlings appear stand the pans near to the roof-glass, and transplant the seedlings as soon as they are large enough into shallow boxes filled with the same compost as before, but in a slightly coarser condition, growing the plants on in the same house. An important

point is to keep the plants growing freely, as any check the plants may receive, especially in their infancy, such as getting very dry or overcrowded, is almost sure to end in a large percentage of them prematurely running to seed.—F. W. GALLOP.

Seakale.—Wherever this vegetable is appreciated a point should be made of growing a breadth outdoors to furnish a supply after or to succeed the last lot of forced crowns inside. This late Seakale requires nothing further in the way of attention to secure good returns than to exclude all light from the crowns. This can be ensured in various ways, such as the employment of pots, boxes, and so forth, but the least troublesome method is to cover each group of crowns with a good mound of fine ashes or soil. The Kale secured by this means comes perfectly blanched and

a trial. We have no lack of excellent varieties of both long and globe-shaped rooted varieties. Quite recently I was told by a lady she strongly objected to the globe-shaped Beets, as they lacked colour. If seed of the Globe Beet of a good strain is grown there is no comparison with the globe-shaped roots of the old days, which were of a poor colour and of inferior quality. I have found Intermediate an excellent introduction and one that may with advantage be grown on shallow soils. The flesh is of a deep red colour. In addition it is of excellent quality and a good keeper, as the roots, if given cool storage, may be had well into May. I would not advise too early sowing on poor land or shallow soil if the roots are required for winter and early spring supplies. If an early supply is wanted it is advisable to

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM JANUARY 27TH. — *Berberis japonica*, *B. Mahonia*, *Winter Sweet*, *Andromeda floribunda*, *Jasminum nudiflorum*, *Forsythia suspensa*, *F. spectabilis*, *Edgeworthia chrysantha*, *Coronilla glauca*, *Genista hirsuta*, *Gorse*, *Cydonia japonica*, *Andromeda japonica*, *Daphne Dauphini*, *D. Laureola*, *D. Mezereum*, *Periwinkles*, *Garrya elliptica*, *Rhododendron Nobleanum*, *R. praeox*, *single pink Camellia*, *Ericas* (in variety), *Laurustinus* (in variety), *Parrotia persica*, *Strawberry-tree*, *Hamamelis arborea*, *H. Zuccariniana*, *Snowdrops* (in variety), *Violets* (in variety), *Cyclamen Coum*, *Trilectia uniflora*, *Violet Cress*, *Corsican Hellebore*, *Christmas and Lenten Roses* (in variety), *Picaria grandiflora*, the *Carpathian Snowflake*, *Tufted Pansies*, *Crocus Imperati*, *C. biflorus*, *C. Susianus*, *C. Sieberi*, the *Greek Anemone* (*A. blanda*), *Anemone coronaria* (various), *Winter Aconite*, *Eranthis hyemalis*, *E. cilicis*, *Narcissus pallidus praeox*, *Winter Heliotrope*, *Saxifraga* (*Megasca*), *Saxifraga apiculata*, *Polyanthus* (in variety), *Lithospermum rosmarinifolium*, *L. Heavenly Blue*, *Hepaticas* (in variety), *Blue-eyed Mary* (*Omphalodes verna*), *Prostrate Rosemary*, *Iberis petraea*, the *Cornelian Cherry* (*Cornus Mas*), *Spring Bitter Vetch* (*Orobis vernus*), *Lungwort* (*Pulmonaria saccharata picta*).

WORK OF THE WEEK.—Fresh tripods for Clematises have been fixed where the old supports had given way. Formerly, peeled Chestnut poles about 2 inches thick were used on account of their durability, but this wood not being available this year, Larch poles are being used. These are cut into lengths of 10 feet, 18 inches of this being in the ground. This part, in order to preserve it, has been given a coat of tar. A shrubbery which had become somewhat overgrown has been thinned and rearranged. *Eucryphia pinnatifida*, *Viburnum macrocephalum*, *Gleditschias*, etc., which had been planted at the back so as to be sheltered when in a small state, have now been placed in the foreground. A small group of *Plagianthus Lyalli* and a few other tall-growing shrubs have been transferred to more roomy quarters, where they will benefit from a background of native Hollies. Pruning and tying in of climbing plants on pergolas and arches are being done. Many of these climbers are already in active growth, especially Clematises, and, should sharp frosts set in, they are bound to suffer. The ever-green Clematis *Armandi* has already made over a foot of new growth. The soil of a long, narrow border running along the east side of the house and which for many years had been occupied by *Hepatica triloba* having become worn out, it was decided to renew the border with fresh soil and plant afresh, as in this position the *Hepaticas* have been such a feature every year that their absence would be disappointing. The soil was taken out to the depth of 1 foot and used for surface-dressing other borders. The new border was then made up with a mixture of maiden loam, leaf-soil, wood-ashes, lime, and sand. About 150 plants of the old single blue *Hepatica triloba* have been put out, and others will be added later. A batch of the Giant Forget-me-not has been planted beneath a shady wall, and a few plants of *Cyclamen Coum* have been given a place away from direct sunshine. A lot of *Tropaeolum speciosum* having come to hand, a place has been provided for it where it will be partially shaded. In some instances it is intended to fall over

Tuberous Begonias in a hanging basket.

tender, and a slight rinsing in cold water at once frees it of any soil or ashes that may become attached to the stems or lodged in the axils of the leaves. If the plot is divided into two or three portions, and the crowns in the first are covered down now, those in the second in three weeks' time, and in the third about the middle of next month, a good succession will result. The great thing is to see that a sufficiency of ashes or soil is mounded over the crowns, so that when growth takes place no portion of it can protrude and become discoloured. The first lot in my case has been covered with fine ashes after the removal of dead leaves and so forth.—G. P. K.

Beetroot Intermediate.—Those who object to the long-rooted Beets or who have a poor soil to deal with may with advantage at this season, when ordering their stock of vegetable seeds, give Intermediate

make two sowings, roots from the earlier sowing being valuable for a summer supply.—C. R.

Asparagus beds will be forked over as lightly as possible, taking care not to injure the crowns. Undecayed manure on the surface will be removed and dug into the alleys. This will lighten and enrich the soil for future top-dressing. As the work proceeds, some of the finest soil is placed over the crowns where necessary, regulating the quantity by the amount of covering already over them. When the work is finished the crowns should not be lower than 6 inches from the surface, whilst the soil should be light and rich.—F. W. GALLOP.

A good Celery (W.).—There are so many kinds of Celery nowadays that the inexperienced are often puzzled which to choose. Were we restricted to one sort only, we would certainly prefer Leicester Red. No better Celery could be grown for weight, crispness, and quality.

boulders, in others ramble among Hollies, Camellias, Thorns, and various other trees and shrubs. E. M.

Nusser.

SOUTHERN COUNTIES.

Pot Vines.—The shoots, being sufficiently advanced to allow of discrimination being exercised in regard to the selection of those showing the best bunches, the surplus shoots should now be pulled off. To induce the bunches to lengthen out quickly a further rise of temperature both by night and day is necessary. The shoots should be stopped with the finger and thumb at the second leaf beyond the bunches. The tying down of the shoots now requires attention, but its final accomplishment is best deferred till after the Vines have flowered and the berries set.

Bedding plants.—With the starting of a Peach-house to supply ripe fruit in the early part of July the potting of the above will now take place, as the plants will be accommodated therein on a portable stage erected in the body of the house. To economise space long toms or rimless pots will be employed, a piece of rough loam or Moss being placed in the bottom of each in lieu of crocks. A mixture of two parts loam and one of leaf-mould, with a little sand added, is used, and to save time the potting will be done in the house itself. The object in dispensing with the crocking of pots is to facilitate matters when planting out takes place, and that the plants may the more easily be knocked out of the pots the latter are washed before being used. The numbers will be carefully noted down as each variety or kind of plant is potted, with a view to ascertaining if there is a shortage and the number that will have to be propagated to make good the deficiency. Some few things, such as the smaller-leaved varieties of scented Pelargoniums, Verbenas, and Heliotropes, for instance, will for a time be placed in a warmer house to give them a start.

Fuchsias.—These will be taken from their winter quarters and pruned into shape, and then placed in the above-named house to break. The older plants will be used for supplying cuttings for propagating young stock for greenhouse decoration in late summer and autumn, and be afterwards planted out. The young plants raised from cuttings last year will, after they have broken, be partially shaken out and repotted, and grown on into large-sized bushy specimens for house decoration. Young shoots taken with a heel root quickly in a sandy compost in a propagating-case, 6-inch pots being suitable receptacles in which to root them.

Zonal Pelargoniums.—These have, generally speaking, been under a cloud for the past few years, but are again coming into favour for autumn and winter decoration. Nothing brightens the greenhouse and conservatory more during the dull months of the year than Zonals, and where accommodation can be found for the growing of the plants a collection should be found wherever a display is required at the season named. To grow them successfully they must be accorded a good long season of growth, and the wood should be well ripened by the end of summer. Propagation should, therefore, begin now. The best way is to insert the cuttings singly into thumb-pots, placing a pinch of sand at the base to facilitate callusing. When rooted they can then be shifted into larger pots without disturbing the roots. The cuttings may also be dibbled in round the sides of 6-inch pots. If placed in genial warmth they speedily root.

Perpetual - flowering Carnations.—Several hundred cuttings will now be taken, the number consisting of the varieties most appreciated. These cuttings will be dibbled into pure sand, in which they root sufficiently to enable potting off to be done in about four weeks' time.

Gloxinias.—These will be overhauled and placed in the early vinery to start, after which they will be shaken out and repotted. This method occasions fewer losses from dry rot of the tubers than when they are shaken out prior to giving them a start in heat.

Amaryllis.—The bulbs having had a good long season of rest, and as new roots are just beginning to be made, the shaking out and repotting of the same will now be taken in hand. When finished, a vinery just being started will provide them with congenial quarters until the flower-spikes push up.

Early Potatoes.—The soil has at last become sufficiently dry to allow of the first planting taking place on a border facing southwards. This having been manured and dug some few weeks ago, and the soil being light, it is now in excellent condition for the reception of the seed-tubers, which are being planted in drills drawn 2 feet apart. A good breadth will at the same time be planted in a sheltered position in the open. Varieties favoured for early work are Duke of York, Early Puritan, Edinburgh Castle, and, for general household purposes, Ninetyfold.

Pea-sowing.—A commencement has at last been made with the sowing of Peas outdoors, wet weather having hitherto caused its postponement. The drills are being drawn to run north and south, and stand 6 feet asunder, which admits of the vacant space between the rows being utilised for the growing of early Spinach, Turnips, Radishes, and Lettuces. Part of the sowing is taking place on a south border and part in the open, first earlies being used for the former and first and second early varieties for the latter, which will ensure a good succession. Seeing that the soil is yet very moist and cold, the drills are not being drawn very deep or quite so deep as usual, and the seed sown more thickly than is, under normal conditions, necessary.

Shallots.—The wet condition of the soil has prevented these being got out as early as usual. The planting in rows 1 foot asunder with a distance of 9 inches between the bulbs will now take place. A piece of ground in good heart has been allotted them, and as the demand is generally a fairly large one this is of sufficient area to allow of the planting of several long rows. The bulbs are pressed into shallow-drawn drills just deep enough for the soil when it is returned to hold them firmly in place. A good stock of Shallots is always useful, as, when Onions begin to get scarce in spring, they can in many ways be made to do duty for them.

Garlic.—Much less of this is required, a good row yielding sufficient bulbs for the season. The planting is done under precisely the same conditions as the preceding.

Chives.—These help to prolong the supply of Onions, as the tops can be used in lieu of the latter for the flavouring of soups and so forth. Now is the best time to lift and divide the clumps and replant them in a fresh position on the herb border in rows 18 inches apart with a distance of 9 inches between the plants.

Scorrel.—This is occasionally in request as a substitute for Spinach. To obtain a good supply of leaves the plants require generous treatment in the way of some

well-rotted manure dug in between the rows. Division of the clumps can also be effected now and the pieces replanted in another part of the herb border after it has undergone a course of preparation in the way of manuring and digging. The rows should stand 18 inches asunder and the plants 1 foot from each other. If care is taken to prevent the plants running to seed by cutting out the flower-stems when they push up, the clumps will yield a good supply of leaves for several years in succession before it is again necessary to lift and replant.

Common Thyme.—As this is apt to become untidy if left alone for any length of time a portion of the stock should be lifted, divided, and replanted at this time of year. By these means the plants are not only kept within bounds and look much neater, but when the herb is required for the kitchen an abundance of young shoots is thus always ready to hand.

Horseradish.—This is in request through the whole year, and to keep up a good supply it is necessary to lift and replant a portion of the bed each season, using sets consisting of straight, medium-sized pieces of roots from which all side roots have been rubbed off and with or without a crown or bud on the top. Plant with a bar in holes 18 inches deep.

Spinach.—A few drills have been sown to augment the supply of winter Spinach, the variety being the Round-leaved or summer kind.

Radishes.—A long drill of each of the following has also been sown, viz., Red and White Forcing (Turnip-rooted) and Early Frame (long-rooted). Owing to the partiality of birds for the seeds the rows have to be protected with wire seed-guards.

Lettuces.—For sowing now preference is given to the quick-growing, small-hearted Cabbage varieties, but a sowing is also made at the same time of the dwarf-growing Cos variety named Nonsuch, as it follows close on the heels of, if it is not ready for use before the preceding are over. A. W.

MIDLAND COUNTIES.

Strawberries.—The plants set out last autumn will be examined when the ground is not in a sticky condition, and made firm. Any gaps that occur in the beds will be made good with plants reserved for the purpose. The surface soil should be hoed frequently as soon as the weather is dry enough. Where it is intended to make fresh plantations next autumn a piece of ground which has been trenched and liberally manured for the first and second early varieties might be selected. Such a piece of ground would be in excellent condition for the Strawberries after the Peas have been gathered, which will be early in August. It would then require to be merely hoed over and have all the weeds and rubbish removed. A good dusting of soot might be applied and forked into the surface. Strawberry-beds are frequently kept too long in bearing, although certain varieties in some soils will continue to fruit longer than others. As a rule, a period of three years is long enough for a bed to bear.

Bush fruits.—These being more or less surface-rooting, quickly exhaust the top layer of soil, and an annual mulching or addition of fresh soil is necessary if the best results are to be obtained. A mixture of fibrous loam and well-decayed manure to which a proportion of bone-meal has been added forms a very suitable top-dressing. The planting of bush fruits should be completed without delay during snitable weather. If planted in quarters

or rows in the open ground allow a space between them of 6 feet to 7 feet each way; if trained against walls or to wires a distance of 3 feet or 4 feet apart will be sufficient. Gooseberries and Currants planted against a north wall will furnish a supply of fruit for many weeks after the general crop is over.

The fruit-room.—Apples are keeping well with me this season. They need to be examined frequently and all fruits showing signs of decay removed, laying the remainder out thinly over the shelves and benches. The room is kept cool, not too dry, and ventilation afforded on suitable occasions to sweeten the air. Late Apples are always valuable, and for this reason the season should be lengthened as much as possible. Cooking Apples in use from this date onwards include Alfriston, Annie Elizabeth, Lane's Prince Albert, Norfolk Beefing, Roundway Magnum Bonum, and Wellington.

Calanthes.—All the plants having passed out of bloom, they will be given a short period of rest, withholding water from the roots and arranging the plants closely together on a dry shelf in a house where the temperature does not fall below 60 degs. The plants will be kept in this position until new growths begin to develop at the base of the young pseudobulbs, when it will be necessary to repot them.

Pelargoniums of the show and fancy sections make useful pot plants, and are almost indispensable for conservatory and greenhouse decoration. They may be had in bloom at almost all seasons of the year, but it is after the bulbous plants are over that they are especially valuable, continuing in bloom until flowers are plentiful out of doors. Old plants that were started in September are well rooted and have been placed in their flowering-pots. Plants raised from cuttings inserted last summer have also been given a shift into 5½-inch pots. A suitable rooting medium is composed of rich fibrous loam, a small amount of well-decayed manure, lime-rubble, and bonc-meal.

Border Carnations.—Owing to the damp atmosphere in this district it is necessary to winter these in pots; they will be planted out at the first favourable opportunity. If planted early they have a longer season to become established, and, in consequence, flower more profusely. It also often happens that the weather in February is more favourable for planting than March and April.

East Lothian Stocks sown in January are large enough for transferring singly to 60-sized pots. After potting they will be kept growing freely near to the roof-glass in a cool pit. Later on they will need hardening off preparatory to planting out of doors.

Lupinus polyphyllus.—This species does splendidly grown as an annual. It can be flowered the same year by sowing it in the open, but it is worth the extra trouble to raise the plants under glass. Three-inch pots are a suitable size, placing one seed in each. The plants may be put into the border or bed in April. Several of the annual Lupins are also worth cultivating, but it is too early to sow any of these.

Pentstemons.—To increase named varieties of Pentstemons or a distinct and effective variety it is usual to propagate them from cuttings. If seed of a good strain is sown excellent plants may be obtained for putting out in the spring. The plants may, perhaps, be a little later in flowering than those raised from cuttings, but, nevertheless, they may be expected to produce a wealth of bloom, which will be continued until severe frosts occur. Among the

seedlings there may be certain varieties worth saving for another season. Sow the seeds in pans or boxes provided with good drainage and filled with a light, sandy compost. Sow thinly and evenly, and just cover the seeds with some of the finest of the soil, afterwards pressing the surface firmly and evenly. Water through a fine rose-can and place the pans or boxes in a house where an atmospheric temperature of 60 degs. is maintained. As soon as the seedlings can be handled prick out into boxes, using a moderately rich, open compost, placing the small plants at a distance of 2 inches apart. When they have recovered from the check of transplanting remove them to a cool house and later to a cold frame.

Brussels Sprouts.—A small sowing of this vegetable will be made to furnish plants for cropping in September. The seeds are sown in boxes and germinated in gentle heat. As soon as the seedlings make their appearance the boxes will be removed to a cold pit. When large enough to handle the seedlings are pricked off into beds, putting them 4 inches apart. The pit should be kept closed for a few days, but when growth commences air must be admitted to prevent the plants becoming drawn. After a time the lights should be removed gradually until the plants are ready to put out early in May.

Peas.—As soon as the ground is in working condition a sowing of early Peas will be made. Choosing a fine day, the ground will be lightly forked over in good time in the morning to dry. The rows should not be closer than 4 feet apart. I sow the earliest Peas wide enough apart to allow a sowing of Spinach to be made between them. The first sowing should be made a little thicker than the later ones. I prefer Pilot for first crop, with Early Marvel as a succession. Peas in 3-inch pots sown early in January are afforded plenty of ventilation, avoiding cold draughts at all times. Though moisture-loving plants, Peas will quickly suffer if overwatered. The growths will need supporting in good time with sticks.

Turnips.—A small sowing will be made on a very sheltered border as soon as the soil is in a fit condition. As there is a danger of the plants running to seed, only a small quantity of seed is sown at a time. When the seedlings are through the ground frequent dustings of soot and wood-ashes are afforded, and the surface of the bed lightly stirred with the Dutch hoe. Early Milan is a good variety for the first sowing.

Lettuces, Radishes, Carrots, and Cauliflowers.—Further sowings of these will be made during this month on mild hotbeds.

F. W. GALLOP.

SCOTLAND.

Tufted Pansies.—In the course of the week the cold frames into which the cuttings of Tufted Pansies were put during late autumn were inspected. On the whole, the cuttings have rooted well, and, with the exception of a few of the young plants which have suffered from damp, they are satisfactory. As early in February as the state of the soil permits, the Celery trenches for first crop will be got ready, and the Pansies removed to a prepared bed in the trenches. A little manure will be used, and 3 inches or 4 inches of sifted vegetable mould will be placed on the top. The young plants are then put out rather closely, and, under such conditions, they soon go ahead, making well-rooted and compact specimens which can be lifted with excellent balls when planting time comes round.

Similar treatment is followed in the case of Calceolarias, and equally good results are obtained.

Marguerites.—Only sufficient plants of the ordinary *Chrysanthemum frutescens* and of the double Mrs. Sanders are retained to provide stock for summer planting. The latter fine variety does not produce the right kind of cuttings at all freely in late autumn, so a number of plants is potted up and cut back. Having been recently given a fairly brisk heat, good cuttings are being freely produced, and, as they become ready, are slipped off with a heel and put into the propagating-pit. They soon emit roots, and, when boxed up, they, in their turn, provide cuttings until the necessary number has been secured. In the case of the commoner single variety the cuttings put in during October are now sufficiently advanced to permit of the tips of the plants being utilised for propagating. The leaf-boring maggot has been at work during the winter months and is being dealt with.

Lobelia Kathleen Mallard.—Although discarded for outside work a few plants of this double-flowered Lobelia are not without value under glass, and, during the week, a few cuttings were taken from plants saved over winter and put into the propagating-pit. Formerly used to some extent in summer bedding, it was found that during rainy spells the wet lodged among the flowers, which speedily damped off.

Lobelia floribunda.—After having lost sight of this very useful winter-flowering plant for a number of years some stock pieces were purchased, and these have been given a brisk heat in order that cuttings may be produced. As quickly as these become available they will be put in until the requisite quantity is obtained. The old plants will then be cut back, and when fresh growth is visible they will be repotted and given cool treatment until it is possible to place them out of doors for the summer upon a bed of ashes.

Nerines are still being given plenty of moisture, but they are only receiving a very moderate allowance of heat. Nerines flower best when undisturbed for a number of years, but when the foliage has thoroughly ripened off it will be necessary to break up several pots, owing to the increase of the bulbs. The pressure, indeed, is so great that some of these are forced nearly out of the pots, so that no benefit is derived from delaying repotting longer. Good loam and leaf-mould in equal proportions suit these showy bulbous plants well, with, of course, sufficient sharp sand to keep the mixture porous. The varieties to be dealt with are N. Bowdeni and N. Fothergilli, both useful sorts.

The rock garden.—An opportunity was taken in the course of the week to cut over such things as required it and to reduce others, after which all leaves, etc., were cleared out of the crevices. Leaves are rather troublesome just at this particular place, for there are many trees near to hand, and a wind from the south-west invariably blows up a fresh supply from the wood. Some plants are inclined to overrun their allotted spaces, notably the Cranesbill of different kinds, Veronica prostrata, and some of the mossy Saxifrages. These were rather severely handled in order to give choicer things more room. *Primula denticulata* is on the point of flowering, and *Narcissus minimus* comes on apace, although it will not bloom for some considerable time yet. *Anemone stellata* is pushing on rapidly in sheltered places, and will, apparently, be in bloom at much about its usual time. Damp seems

to have been fatal to some of the finer pinks.

Greenhouses.—The last Chrysanthemums of the season having been cut, advantage was taken of a stormy day to clean out and re-arrange a span-roofed house. A good batch of *Cineraria stellata* was made use of. The plants, just on the point of blooming, have been kept quite cool until now, and, as a result, are free of aphids. Nevertheless, when staging was completed, the house was vaporised on two successive nights, and this will probably save any trouble in the future. A quantity of *Arum Lilies* was also staged, as well as bulbs of different kinds. *Salvias*, now practically over, were dispensed with, excepting about half-a-dozen plants of each variety. These have been assembled on a stage and will be grown on in a comfortable temperature in order that cuttings may be produced as quickly as possible. Lack of sun is responsible for rather brisker firing than is usually given, and no unnecessary water is thrown about. *Clematis indivisa lobata* is now making excellent growth, and will be useful at a later date. A good batch of the variegated *Hydrangea hortensis* has been put into quite a cool house. These will ultimately be planted out of doors. A dozen plants of *Antirrhinum Nelrose*, now showing the flower-spikes, were also made use of, as well as odds and ends from the stove. Air is given freely on all suitable occasions.

Chrysanthemum cuttings.—In the course of the week a finish was made with the insertion of Chrysanthemum cuttings. The batches previously put in are now taking hold, so after the final lot was put in the old stools were taken to the heap of soil which accumulates from various sources, for the balls are much too valuable to waste. By-and-bye these will be broken down and sifted, the soil thus obtained being useful for seed-sowing and other purposes. At the same time all the pots were thoroughly scrubbed, the crocks collected and washed, and laid aside in readiness for the time when they will again be needed.

Hardy Chrysanthemums.—The stools lifted in November and wintered in a two-sash cold frame have done well, and cuttings are now ready in some quantity. It is early enough to begin propagation, but a few dozens have been put in. Generally speaking, it is better to delay propagation of hardy Chrysanthemums until the end of February. The cuttings root more readily at that time, and there is less chance of losses from damping. After growth begins the young plants ought to be grown on steadily, any check in their earlier stages being difficult to make good at a later date.

Seed Potatoes.—The earlier lot of seed Potatoes is being got ready. If placed in shallow boxes and packed on end closely, being afterwards covered with mats, the eyes soon start into growth. As soon as these are visible the mats are taken off and every endeavour made to keep the shoots as sturdy and robust as possible. For earliest crops no cut seed should be employed, and superfluous shoots must be rubbed out in good time. Late varieties should be inspected from time to time, and any doubtful tubers promptly removed.

Flower-stakes.—It has been absolutely impossible during the week to do any digging, or, indeed, to go upon the soil at all. In order to further the work in other ways advantage was taken of a comparatively dry spell to cut 500 or 600 stakes from an avenue of pollarded Sycamores. These trees are pollarded every few years, and annually provide plenty of excellent

stakes suitable in an especial degree for Chrysanthemums in pots. These are cut at a length of about 5 feet, and are then dressed and pointed. Although the stakes only last a season, yet they are worth the trouble involved. One grudges to cut Bamboo canes when they are too long, because thereby they may be spoiled for other purposes, but no compunction is felt in reducing the stakes referred to to a suitable size. Further quantities will be cut from time to time as opportunity offers until a sufficient number has been secured. Smaller sizes of the same material are useful in many ways, they are easily obtained, and are quite as good for many purposes as purchased stakes.

W. McGUIFFOG.

Balmac Gardens, Kirkcudbright.

CORRESPONDENCE.

Questions.—*Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly written on one side of the paper only, and addressed to the EDITOR of GARDENING, 63, Lincoln's Inn Fields, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, the name and address being added to each. As GARDENING has to be sent to press some days in advance of date, queries cannot always be replied to in the issue immediately following their receipt. We do not reply to queries by post.*

Naming plants.—*All who wish their plants to be rightly named should send fair examples of each—the stem, leaf, flower, or fruit. (Snippets of leaves and points of shoots are useless.) Not more than four plants should be sent in any one week by the same correspondent. Where more than one kind is sent they should be numbered. Of course the fruit should always be sent.*

Naming fruit.—*Several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. We can undertake to name only four varieties at a time.*

PLANTS AND FLOWERS.

Green mould on Azalea stems (*A. R. Duncan*).—Are your Azaleas grown in pots or are they the hardy ones? We are assuming you are referring to *Azalea indica*. A green mould, such as you refer to, is apt to attack old plants, more particularly if the roots are in a bad condition, in which case the only remedy is to re-pot them. An excess of moisture would also tend to encourage this fungoid growth, for a fungus it undoubtedly is.

Gladiolus spawn (*L. M. S.*).—The bulbets or spawn should be taken off in the autumn when you lift the corms. Store them for the winter in sand in a cool greenhouse or in some place where frost will not reach them. In the spring, just as they begin to grow, plant them in a nursery bed of light, rich, sandy soil, lifting and storing the bulbs in the autumn, and treating as advised above. After two years' growth most of them should bloom well.

Primulas, Chinese, damping (*F. Longfield*).—You have buried your Primulas too deeply. These plants have soft, sappy stems, and are very susceptible to injury from damp if the wet accumulates near them, especially close to the base of the leaf-stems, as has been the case in the plant you send us. The plants should, as it were, just sit on the soil, and not be buried into it. If they have in any way become drawn, then it is usual to support them with short stakes put in around them, and tie them up with matting.

Treatment of Marguerites (*H. P.*).—The Marguerites can be cut back now a little, and the shoots they put forth, when about 3 inches or 4 inches in length, would make excellent cuttings, and should strike root freely. Young plants so raised will bloom in a small way in the summer; but if they are planted out in the open ground in May, and encouraged to grow by keeping the bloom-buds pinched off, watering, etc., and lifted and potted up towards the beginning of September, fine plants for winter blooming can be depended on.

Smilax from seed (*J. R.*).—Sow the seeds in a pot or pan in a mixture of loam, peat, and sand, plunge in a good hotbed, and keep the soil fairly moist. Spring is the best time to sow. When up and growing pot the seedlings singly, grow on in warmth, and when strong enough plant them out in a well-drained bed of nice light, rich soil, training the shoots singly to strings. The plant grows best in a mild stove or intermediate temperature, with a fairly moist atmosphere and light shade.

Gesnera (*A. Subscriber*).—The leaves you send are those of a Gesnera, but which we cannot determine without flowers. After their flowering season is over, Gesneras perfect their growth, and then go to rest, at which period scarcely any water should be given. Then on the return of spring they should be turned out of their pots, and the curious underground rhizomes or tubers picked out of the old soil. A suitable compost for them consists of equal parts loam and leaf-mould, with a liberal admixture of silver-sand and well-decayed manure. In potting, the upper part of the tuber should be just covered with the soil, which must be kept slightly moist till growth recommences. These Gesneras are much benefited by being started in the temperature of an intermediate-house, but in the summer they will succeed in the greenhouse. They are readily increased by their underground rhizomes, which are freely produced.

FRUIT.

Melons in frames (*J. F. Riley*).—The usual way is to have two plants to each light. Unless you can have a hotbed, it is much too early to think of planting in frames, April being quite soon enough to make a start. So early in the year there is always the chance of cold winds and sharp, frosty weather. Even those who are well equipped, as regards labour and material for maintaining the limes in a state of efficiency and in covering the frame with waterproof covers and mats at night, find the growing of Melons in frames at this season no child's play, and unceasing attention on the part of the grower is necessary if success is to be had. The end of March would be quite soon enough to sow the seeds.

VEGETABLES.

Market gardening (*Y.*).—This is a very extensive and varied business, and a very important one, and the first thing to do before you invest your money in it is to go and work in some good market garden, otherwise you will probably waste your time as well as lose your money.

Manuring a garden (*Mrs. F. J.*).—There is no doubt that for general garden purposes the use of a good dressing of mixed farmyard and stable manure would be most desirable, or supplemented by artificials selected for each crop. Many people are in the same position as yourself, and have to do the best they can without the dung. In regard to a general artificial manure, you cannot now obtain potash at any reasonable price, if at all, and the Potatoes will have to do without this. You should use some superphosphate or basic slag at once, and when the crops are beginning to move, or just before, give a dressing of from 1 cwt. to 2 cwt. per acre, or even more, of sulphate of ammonia, which is a home-made nitrogenous manure, and easily obtainable. In place of the sulphate, you may, if you prefer it, use nitrate of soda or nitrolim, but any one will be efficient. The dressing of slag may be at the rate of about 5 cwt. per acre; and of superphosphate, say, 3 cwt. to 4 cwt. A good manure for Potatoes would be $\frac{1}{2}$ cwt. nitrate of soda, $\frac{1}{2}$ cwt. sulphate of ammonia, 2 cwt. dissolved bones, 2 cwt. superphosphates, and 1 cwt. of sulphate of potash. But you will probably find it simpler to make use of the general dressing we have suggested, though the best and most economical way of using artificials is to adapt the dose to the particular crop, and whenever possible use them to supplement a dressing of well-decayed manure. The leaves possess value, and when well decayed should be mixed with the soil, which they will open, warm, and enrich, though it is easy to exaggerate their manurial value.

SHORT REPLIES.

A. P.—We should not destroy the tree, but plant the creepers against it as it is. The flowers of the climbers will be far more effective when seen through the background of green leaves.—*A. R. Duncan*—*Kalmia nana*, syn. *K. pumila*, is merely a dwarf form of *K. angustifolia*. We do not know what the variety of *Rosa* you refer to as *R. nana* is.—*Mrs. J. W. Procter*.—We have never heard of the Apple you mention, and have failed to find the name in any fruit book we have.

NOTES OF THE WEEK.

The White Hepatica in bloom in January.—The white variety of the Hepatica (*Anemone Hepatica alba*) was in full bloom in the garden of Mr. Hornel at Broughton House, Kirkcudbright, on January 29th. It is, I think, unusually early. My own garden records, going back to 1891, though not kept annually, do not show *A. Hepatica* in bloom at such an early date.—S. ARNOTT.

Spring flowers in Scotland.—The progress made by bulbs during the past week or two has been phenomenal. Snowdrops have come on very rapidly, and to-day (January 28th) a colony of *Crocus* is in bloom. This is earlier than usual. The bulbs in question are, however, in a sheltered position, but in other places the display will shortly be general. Primroses, too, are beginning to be fairly numerous.—W. MCG., *Balmac, Kirkcudbright*.

Myosotis dissitiflora.—I note with surprise "Byfleet," February 5th (page 70), speaks of *Myosotis dissitiflora* as a shy seeder and difficult to keep a stock of. Perhaps my experience in Cornwall may interest him. Here I have had it for several years, and it never fails to give plenty of self-sown seedlings in all sorts of strange places. In hedges and paths I usually find literally thousands of seedlings, so many in fact as to be a nuisance were not this *Myosotis* such a priceless thing.—G. ALGAR-TEMPLE, *Scorrier, Cornwall*.

Clematis integrifolia Durandi.—A proposal of the article in GARDENING ILLUSTRATED of January 22, relative to the *Clematis integrifolia Durandi*, I am sending you, in a separate cover, an old catalogue of our firm of March, 1874. From it you will see that this fine plant was introduced in that year by my father, who had bought the entire stock of it from the raisers, M.M. Durand frères, of Lyons. As my father had dealings of a cordial nature with M.M. Thibaut and Keteleer, he was able to send them some plants at the time he brought out this novelty.—E. LEMOINE, *Nancy*.

Crocus Sieberi.—I had flowers of this in a sunny border fully open in the scant sun of a January day on the 30th of that month this year. My earliest record was in a former garden close to the sea, where in 1898 it bloomed on January 25th. The presence or absence of sunshine is an important factor, and it is not possible to

make an exact comparison, as the flowers were ready to expand some days before. *C. Sieberi* has pretty pale purple flowers with an orange base. The anthers and filaments are orange and the stigmata orange-scarlet.—DUMFRIES.

Abelia chinensis.—I envy those who can grow this fine shrub in the open. It has been repeatedly tried, but without such success as would warrant its retention. Even given a choice place on a warm wall with a southern exposure the plant never appeared to thrive. It is, evidently, a case of a few degrees in winter making all the difference, for when grown in pots in an unheated house *A. chinensis* does well.—W. MCG., *Balmac*.

Winter Aconites.—Mr. Arnott's note concerning the blooming of Winter Aconites at Broughton House on January 10th was interesting. *Balmac* is but five miles from Broughton House, yet it was not before the 16th of the month that the first flowers of Aconites were observed. In Mr. Hornel's garden, however, there are more shelter, and, perhaps, a more congenial soil, which, combined with the lower altitude, most probably account for the week's difference. Now (January 26th) the Winter Aconites are at their best.—W. MCG., *Balmac*.

Crocus Imperati.—This varies a little, but the ordinary form is perhaps as attractive as any. It has good-sized flowers, which are of a pale purple when open, the exterior of the segments a pretty buff feathered with dark purple. In some forms the purple feathering is absent, but this is no gam. I understand the unfeathered form comes from a different locality. It flowers, as a rule, rather earlier than the other. The white variety, *C. I. albus*, is not so vigorous as some of us would like. The form sold as *C. I. longiflorus* is also handsome. A variety, *C. I. Reidi*, with rose-coloured segments, is figured by Mr. George Maw in his monograph of the genus. *C. Imperati* was in bloom with me on January 30th.—S. ARNOTT, *Dumfries*.

Ardisia crenulata.—Upon a recent visit to Kew Gardens I was very pleased to see in No. 4 house (the flowering-house) some very fine examples of *Ardisia crenulata*. These were admirably grown, having evidently been well cared for from the seedling stage. These plants were bearing a profusion of dark scarlet berries, and in every sense highly decorative. More than fifty years back now this plant used to be

grown for use at Christmas, when its use upon the dinner-table or in vases as single plants in various ways was much appreciated. It was quite a reminder of past times to see it again represented in such excellent style. Like many other valuable plants, it has been thrust aside to give place to soft-wooded plants that can be grown into decorative plants in less than a year.—J. H.

Echeveria retusa.—A few plants of this succulent are useful during the dull months. If grown in a moderate stove heat no difficulty is experienced in obtaining blooms at the New Year, but, naturally, if only greenhouse temperature can be given, the flowers do not appear till spring. For winter flowering the plants ought to be shaken out and repotted in June, being afterwards placed in a cold frame until a vigorous growth has been obtained. A rather sandy soil is essential, and great care is needed for a time as regards moisture. On the approach of winter the plants can be removed to more comfortable quarters, and when in bloom its neat habit and brightly-coloured orange flowers make it welcome. *E. retusa* is useful for room decoration, and lasts well in heated or gaslit places.—KIRK.

The Winter Heliotrope.—I have, unfortunately, some reason to speak bitterly of this plant in the garden. Many years ago it was put out at the foot of a south wall and in a piece of rockwork. In both positions, especially in the latter, it has proved an unmitigated pest, and year by year much time is occupied in trying to get rid of it. As "W." remarks, its place is on a railway bank, but, I fear, railway companies would not welcome its use even there, for it might easily spread through the ballast of the permanent way and take possession. Here, too, are large colonies in the woods. These do not flower at all well, and have ousted the Primroses and Wood Hyacinths. I, therefore, have reason to write in no kind way of *Petasites fragrans*, but I have no desire to be unjust to it, or to any plant which, although a pest here, may be enjoyed by others.—W. MCG.

Notes from Bettws-y-Coed.—Your Editor has hurt my feelings by excising my reference to *Menziesia*, or *Dabecia polifolia*. I suppose he did so lest I should hurt the feelings of some reader of GARDENING ILLUSTRATED. "Notes from Bettws-y-Coed" are intended for various friends who hold the same antediluvian views as myself. Having all their lives

spoken of Saxifrages and Asters they do not care for Rockfoils and Starworts. I wonder whether *Arnebia echioides* has ever been in flower during the last fifty years at this season? On several plants the flowers are not absolutely open, but showing the brightest colours. The show of early Saxifrages has been wonderful. *S. Boydii* alba was in full flower at Christmas, *S. Elizabethæ* never so good before. On *S. Burseriana*, *S. Salomonii*, *S. Cherry-trees*, *S. sancta*, and *S. apiculata* there is also a number of flowers. *Omphalodes cappadocica*, white and red *Saxifraga oppositifolia*, *Rhododendron Silberrad* (a very pretty colour), and wild Daffodils are also in flower. *Daphne Blagayana* is splendid, and I really think *Omphalodes verna*, as it is this season, cannot be beaten for colour.—E. C. BUXTON.

Names of plants.—It is interesting to look at the names of flowers in old gardening books. That excellent guide, Miller, in his *Kalendar MDCCIX.* always calls *Mignonette* "Sweet reseda" or *Mignonette d'Egypt.* Pineapples are "Ananas," but there is no mention of "Girasoles," only Jerusalem Artichokes. In Belgium, by the way, these were called "Topinambours" on the hotel menus in old days. Nomenclature is a difficult subject. While lecturing in America I got hauled over the coals by the reporters for not calling the flowers by their "pet names." But the "pet names" varied in each State I was in. "Baby's Blue Eyes" nearly always meant *Nemophila*, Joe Pye-weed was always *Eupatorium purpureum*, but "Old Maids" for a yellow *Brodiaea* was quite local (Yosemite). No one in California knew what *Ceanothus* meant. It was "wild Lilac" to Californians, "Deers-bush" in parts of California. Consequently, cumbersome though they were, I invariably travelled with my Latin friends packed in my mental portmanteau instead of the fashionable innovation trunk.—A. MARTINEAU.

Trees and shrubs with ornamental bark.—In an interesting article on the above by "D." (p. 29), I was sorry to see no mention of *Cornus florida rubra*, which, apart from its summer and autumn display, is attractive during the winter, when the young wood takes on a charming greyish-blue tint. A good-sized group—the plants averaging 12 feet in height—when the sun streams through the plants, has a quite uncommon effect. Another interesting tree in winter is *Crataegus tomentosa*, whose light-grey bark is noticeable, especially under the influence of sunshine, the older wood appearing almost white from a distance. The young growths do not develop this colour the first year, but remain a pale green. *Elæagnus edulis*, too, is a very attractive shrub at the present time, its rich, golden-brown branches lighting up most effectively on fine days, while every little twig is crowded with buds on the point of bursting. It is used as a foreground to the evergreen species, and, like most things of a deciduous nature, is seen to the best advantage when so treated. The Silver Sage (*Perovskia atriplicifolia*) is not mentioned, but it is a fine plant in winter, where it has attained large dimensions, the long, silvery-grey stems and buds, which in their dormant state retain the well-known Sage odour, being very distinct, and adding to the value of this shrub.—E. M.

New Index and Binding Cases for completed Volume.—The Index to Volume XXXVII. of GARDENING ILLUSTRATED is now ready (price 3d., post free 3½d.). The Binding Case for the same volume is also available (price 1s. 6d., by post 1s. 9d.). The Index and Binding Case can be obtained from any newsagent, or from the Publisher, 63, Lincoln's Inn Fields, London, W.C. If ordered together, the price of the Index and Binding Case is 2s., post free.

FRUIT.

RASPBERRIES AND FAILURES.

We frequently see very inferior canes even in what one may term good gardens. In some cases the soil is at fault, but it is by no means difficult to improve the soil if there is sufficient labour. As Raspberries in a suitable root-run give such an excellent return the labour is well repaid. Many years ago I was told a soil I had to deal with would not grow the Raspberry. This was a thin soil resting on gravel, but by no means difficult to improve, as by removing the lower spit and replacing with heavy loam at least 2 feet deep there was no difficulty whatever in getting good crops. I had to mulch freely in dry summers and only allowed two or three strong canes to a stool. I have found it a good plan to make a new bed yearly on a fresh site. Another failure frequently occurs by leaving too many growths yearly at the base. Unless ample food and moisture are given there must be failures, especially in poor soils. The Raspberry, being such a free-grower and producing so many growths, unless restricted soon deteriorates, the result being weak canes and much smaller fruits. Some land suits the Raspberry so well that it gives very little trouble. I have frequently had new canes of Hornet from 8 feet to 9 feet high and as thick as a man's thumb, whereas in a poor, thin soil they are miserable objects. Though no doubt it is a good plan to plant in the autumn, no one need hesitate to plant now (February) and later with every hope of success, given a good root-run and attention later on. The worst failures I have seen have been on poor gravelly soil. A heavy, clay soil I would prefer, as one can by deep working make such suitable. As previously stated, much better results could often be obtained by planting more frequently. This done, the plants get better culture, and I have often found that by change of site excellent results can be had. I always got much better fruit from canes on a north border under a 10 feet wall. The border was 12 feet wide and 3 feet of that was given up to Morello Cherries. Though late, I got splendid crops, and the canes grown on this site lasted much longer than on open quarters, this showing that it is necessary to have diverse sites to get the best results. In a thin soil I think a little shade advantageous. Such varieties as the strong-growing Superlative will be found of great value. This may be had in fruit longer than most kinds by cutting the canes a little closer down to the stool for late fruits. Much benefit follows the removal of all old fruiting wood; also weak growths as soon as the fruits are cleared, not leaving them a day longer than necessary. F. K.

Fruit prospects.—The fruit garden is getting interesting now. The buds on the Plum-trees are getting forward and are numerous. If the weather is favourable the crop will be good. The last month has been mild and no frost to check things, but frost may come later and do much harm. At present we are living in hope. Hardy plants are springing up in the borders and the gardener is getting out his seed-bags to be in readiness to make small early sowings on the warm, sheltered spots. Hotbeds may be made for early Potatoes and Carrots, and Onions may be sown in boxes under glass and be ready to plant out in April. In the meantime prepare the land for the crop by manuring for Potatoes, not for tap-rooted plants, which should follow a crop like Celery, that does not exhaust the land when well worked and exposed.—E. II.

GARDEN PESTS AND FRIENDS.

NOTES AND REPLIES.

Mildew on Gooseberry bushes.—Would you kindly tell me whether a mixture such as I use for Apple-trees—viz., copper sulphate and caustic soda and lime—will answer the purpose if used for Gooseberry-trees which are suffering from the same sort of mildew, or what looks like the same, or, if not, what do you recommend that is not too costly?—DEVONIAN.

[If the Gooseberry bushes are, or have been, infested with ordinary Gooseberry mildew (*Microsphaeria grossularia*) you should spray them when the buds are about to break with a solution of liver of sulphur (sulphide of potassium), made by dissolving 5 oz. of the chemical in 10 gallons of warm water. As soap adds to the efficiency of the solution dissolve ½ lb. soft soap in the water before adding the sulphide. The bushes should be sprayed again a fortnight after the first application, and as often afterwards as may be necessary, that is to say, should there be a further outbreak of mildew. Be careful to keep weeds from growing around the bushes, as these are apt to act as host-plants and further the spread of the disease. Should it be the American Gooseberry mildew, and not the above, you must at once notify the Board of Agriculture and Fisheries. This is now compulsory, as American Gooseberry mildew is scheduled under the Contagious Diseases Act.]

Silver-leaf in fruit trees.—Re the article appearing in GARDENING ILLUSTRATED on "Silver-leaf in fruit trees," in the issues of January 15th and January 22nd, I should like to give my experience in connection with this fell disease. Some five or six years ago it first appeared in some Plum-trees I planted about sixteen years ago. They were just in full profit. I consulted one or two authorities on the subject of treatment, and they each advised spraying. The remedy recommended was of no use, so, thinking it too mild, I, the next season, tried a caustic spray. This likewise proved of no avail. Then, in the autumn of 1914, I trenched round the trees some 7 feet or 8 feet from the trunks, with the object of checking the roots that had got too far from home. Whilst doing so I found many of the roots (particularly so in connection with the trees mostly affected) covered with what appeared to be lime-wash. On examination I found it was a fungoid growth with a most pungent smell. The thought struck me that silver-leaf comes through the roots, so I purchased some commercial copperas, ground it to a powder, and sowed it on the surface around each tree in November at the rate of ½ lb. to each tree. Last year (1915) I anxiously watched for results, and to my great pleasure only two trees out of twelve showed any signs of the disease—one very slightly attacked, the other so bad that I feared its recovery, so I grubbed it out. I shall watch with great interest the coming season, and shall be pleased to send you an account of results. I shall hope to give another light dressing in the coming autumn. The attack each season, has always been on the western side of the trees. It never seemed to spread in the other directions.—J. W. DARBY, 68, Shaftesbury-road, Gosport.

—A great deal has been written as to the cause of silver-leaf in fruit-trees. What I would very much like to see is some definite means of checking its progress in a young tree and curing it. Many fruit growers—large and small—annually lose trees. One of my acquaintance has in a year to replace as many as 200 trees that have been attacked by it. What a boon a remedy would be! I note, too, the disease is spreading to Currants now. In Apples it has not long obtained a footing.—E. M.

TREES AND SHRUBS.

AZARA MICROPHYLLA ARGENTEA.

This interesting variety of *Azara microphylla* is not yet in commerce. Its leaves are silver with a slightly green centre, and although some fifteen years old, it retains all the characteristics of its variegation and forms a distinct and interesting contrast to the usual dark green species. It is hardy and thrives in well-drained, rich, sandy soil, blooming abundantly in the spring, the delicate vanilla-

beautiful, the brown tips adding a feature to the flowers. This is flowering very well this year and it is interesting to note the difference in this respect among the several varieties in different years. Some of them are not flowering so freely as others this season, and varieties which were good last year are scantily furnished with bloom this season.—S. ARNOTT.

VITIS COIGNETIÆ AND V. THUNBERGI.

Mr. MOLYNEUX (page 68) objects to my description (page 30) of the above, and

Coignetia, I was referring to growers in general, and not to gardeners who are well aware of its distinctness. In Mr. Molyneux's note I find the following: "*V. Thunbergi*, a native of both China and Japan, resembles *V. Coignetia* somewhat in general appearance," etc. This is what Mr. W. Watson says of this Vine in his "*Book of Climbing Plants*": "We owe to China a better knowledge of *V. Thunbergi*, formerly confused with the American *V. Labrusca*. Its foliage at the close of summer assumes rich colours—crimson, green, and yellow. In the garden

Azara microphylla argentea at Ashbourne, Glounthaune, Co. Cork.

like perfume of the flowers scenting the air. R. H. B.

Erica carnea Prince of Wales.—I have recently noted two or three of the newer varieties of *Erica carnea* as of special beauty. Prince of Wales, another of these, has come a little later than Pink Pearl, which it somewhat resembles a short way off, but when seen nearer presents some points of difference. Growing within 2 yards or 3 yards of Pink Pearl, it is a little later and is more graceful in habit. The colour, described by the introducers as a "soft grey-pink," is very

says it is misleading. His statements that *V. Thunbergi* is the best of the family, and that *V. Coignetia* seldom colours, are quite wrong. My notes were taken when these magnificent climbers were at their best, and described accordingly. I can only presume that Mr. Molyneux has not got the true *Vitis Coignetia*.

In describing *V. Thunbergi* as similar, and often mistaken for *V. Coignetia* I rather flattered that variety, for it is of slower and rather weaker growth, yet its autumn colour leaves nothing to be desired. As regards its similarity to *V.*

of Canon Ellacombe, Bitton, it is a striking object; at the same time it is not equal to *V. Coignetia*, also Chinese, which, in the nursery of Mr. A. Waterer, Woking, is magnificent in autumn, when the leaves are at their best. One has only to see it to realise the value of the big-leaved species of *Vitis* as garden plants."

In "*Trees and Shrubs Hardy in the British Isles*," W. J. Bean refers to *V. Coignetia* thus:—

"In the forests of Yezo, according to Sargent, it climbs into the tops of the largest trees, filling them with its

enormous leaves, which in autumn assume the most brilliant hues of scarlet.

"It is in this way that it grows in Mr. Waterer's nursery. It is also very fine at Castlewella and Narrow Water, in Ireland, in both places on a wall, each leaf frequently 1 foot or more across. In this respect, and in the richness of its colour in autumn, it is undoubtedly the finest of all Vines."

Of V. Thunbergi he says:—

"The name has generally been wrongly applied to a form of V. Coignetia, from which it is quite distinct in its comparatively small leaves, deeply lobed, like those of a Fig, and its slender, less woody, five-angled young shoots. V. Thunbergi is grown at Kew and at Bitton, where it turns rich crimson in autumn, and occasionally bears fruit. In my experience it is a rather weak grower, the ends of the shoots dying back considerably every winter."

E. MARKHAM.

— E. Molyneux (p. 68) is quite correct in saying that Vitis Coignetia and V. Thunbergi are distinct species, but he is evidently not referring to the true V. Thunbergi in his note, but to the garden V. Thunbergi typified by the fine plant in Mr. Anthony Waterer's nursery at Knap Hill, which is apparently a fine form of V. Coignetia. The true V. Thunbergi of Siebold is a very different plant, with much smaller and more deeply-lobed leaves. Mr. Bean, in "Trees and Shrubs Hardy in the British Isles," describes V. Thunbergi of Siebold as follows:—"A slender-stemmed, only moderately vigorous, deciduous climber, the young shoots angled, more or less woolly. Leaves variable but deeply three or five lobed, usually 2½ inches to 4 inches, sometimes 6 inches across, heart-shaped at the base; lobes ovate, often penetrating to half, or more than half, the depth of the blade." Of V. Coignetia he writes:—"V. Coignetia, Pulliat (V. Thunbergi, Hort. not Siebold): A very vigorous deciduous climber, reaching the tops of the highest trees; young shoots round, ribbed, and at first covered with a loose greyish gloss; there is a tendril missing at every third joint; leaves perhaps the largest among Vines, being sometimes 12 inches long and 10 inches broad, ordinarily 4 inches to 8 inches wide; roundish in the main, rather obscurely three or five lobed," etc. He further directs attention to the mix up between V. Coignetia and V. Thunbergi. There is certainly a difference between the largest leaved V. Coignetia and the plant introduced about 1893, but apparently the difference is no more than a varietal one, such as is often apparent in various plants. The 1893 plants are scarcely so effective as the Knap Hill specimen or as the large-leaved plants introduced by Messrs. Veitch at a later date.—D.

— Can you enlighten me about Vitis Coignetia and V. Thunbergi. I see in last week's GARDENING ILLUSTRATED E. Molyneux says the latter is much the better, and that V. Coignetia seldom has good autumn colouring. This is quite contrary to my experience as V. Coignetia is glorious in its colouring every autumn, and I should have said much the best of all Vines, as it will go to the top of an Oak-tree in a few years, and, what is more, seems to do the tree no injury?—M. YORKE.

Cutting back Willows and Dogwood.—When and how far back should Golden Willows and Dogwood be cut when they are only grown for the show of their coloured stems in winter?—D. P.

[They should be cut back at once to

within three or four eyes of the base. They will then make good, clean shoots, which will be very effective next winter.]

Magnolia stellata (syn. M. Halleana).—This is of slow growth, and can be kept down to a size which makes it suitable for the small garden, though it never grows tall. I cannot recollect ever meeting with it more than 6 feet or 7 feet high, and Mr. Henry Hoare speaks of it as growing to 7 feet. It is a general favourite and is so hardy and free flowering that it cannot be too highly prized. I have now grown it for a good many years, and it never fails to give satisfaction. The rose-coloured form, M. s. rosea, is very pretty.—DUMFRIES.

VEGETABLES.

Onions decaying.—I am enclosing an Onion, and should be much obliged if you could tell me the cause of it going soft in the top and decaying downwards. I have had a fine crop, which is keeping well, some going like the one I am sending. Several of my friends have had them the same.—W. J. CROSSMAN.

[We are unable to attribute the decaying condition of the Onion sent to anything else but injury from frost, as there are no fungus spores or mycelium to be found in any portion of the affected scales of the bulb. The decay, moreover, is superficial, the inner portion of the bulb, which is commencing to make growth, being quite sound.]

Early Spinach Victoria.—Spinach is always welcome as early in the spring as it can be obtained, and though the Perpetual or Spinach Beet may be considered a good substitute, I do not think it of much value when the true Spinach can be procured. For years I found it a good plan, if the land could be worked, to sow a small quantity late in January on a warm, sloping border. With a light soil this was usually possible, but, if not, I sowed as early in February as the land was dry enough. A large sowing need not be made. In many gardens the land may be unsuitable. I have in such cases used fine old mortar-rubble to great advantage; also in days gone by, when motor traffic was not what it is now, road scrapings from limestone roads. It is also well to sow in rather deep drills. If this is done one may protect with dry litter at the start should the weather be severe. For early work I have found the Victoria an excellent variety and a rapid grower. In the very severe winter of 1895 I was unable to sow this vegetable for early supplies in the open till March was well in, and I found it a great gain to sow seed in 48 or large 60 pots, placing these in cold frames or fruit-houses. These pot-raised seedlings made good material for planting out when the frost broke. The plants made a rapid growth and were very useful, as most green winter vegetables were destroyed that year.—F. K.

Broad Beans.—Plants from the November sowings are looking well. The surface-soil has been deeply stirred and a little earth drawn up to the stems to steady the plants. A full sowing of Green Windsor has recently been made in double drills, at 1 foot apart, with 3 feet spaces between. Broad Beans should be given a deep rich soil, and whatever manure is applied should be thoroughly decomposed.

Parsnips.—Ground intended for Parsnips having been trenched early in the winter should now be forked over on the first favourable opportunity. The Parsnip requires a long season of growth, and the main batch should be sown as soon as opportunity permits, but no attempt should be made to sow seeds of any kind unless the soil is in a suitable condition.—F. W. GALLOP.

GARDEN FOOD.

NOTES AND REPLIES.

Growing Celeriac.—I have read with interest the notes in your recent issues on the cooking of Celeriac. This vegetable I regard as an invaluable one, but, to my misfortune, I can never meet with success in its culture. Would you be so good as to give a cultural note in one of the forthcoming issues of your journal?—G. A. TEMPLE, Scorrier, Cornwall.

[Seed may be raised in spring and the seedlings treated in the same way as Celery. The seedlings may in May or June be planted out in their permanent quarters, care being taken to lift each plant with a good ball. Trenches as for Celery are not necessary, but in a very light soil it may be planted in drills, as these assist in retaining moisture. Well-manured, deeply-dug soil is necessary. The plant is not a success on heavy clay soil unless such aids as old fine mortar-rubble, burnt garden refuse, and lime are added to it to lighten it. The seedlings should have 2 feet between the rows and half the distance between the plants in the row. They give little trouble other than keeping clean, removing side-growths, and watering and feeding. The roots will be full-grown by the end of October, and on the approach of frost they may be lifted and stored in sand, fine soil, or ashes in a cool store, the same as Beetroot. In well-drained soil they may be left in their growing quarters and covered over in severe weather.]

Cooking Beetroot.—I should be much obliged if you would kindly tell me the proper way to cook Beetroot. My cook says that if the least chip is off the end there is no colour in the roots and that a Beet so damaged is not worth cooking.—A. RABY.

[In cooking Beetroot either by plain boiling or baking great care should be taken not to bruise or break the roots in any way, or loss of colour and to a great extent loss of flavour will ensue.]

Early Dwarf Maize.—Owing to so many soldiers coming to this country from distant lands, especially Canada, during the past year, there has been a great demand for this, so little grown in this country. Though I have for years in these pages advocated its culture, it is not a great favourite. There has been a large trade in canned sugar-corn from the States, and this, with a little care, could have been grown in this country. I admit it requires warmth and moisture, but it is surprising how soon the plants fruit if an early variety such as the Early Dwarf noted above is grown. I prefer the Early Dwarf to the larger varieties, although the Early Yellow Six Weeks or Quarantain is excellent. Both the above kinds ripen well in this country and are not tall growers—about 3 feet or less. I have found it best to sow the seeds in small 60-pots under glass, later on thinning to the strongest and planting out in May in deep drills or shallow trenches in good soil, watering freely in dry weather. Given a favourable summer I have had good material from seed sown in the open in early May in rows 2 feet apart, thinning to 1 foot in the row, but it is a great gain to give the plants a start under glass.—W. F.

Bagging Pears.—I am sorry to see, in GARDENING ILLUSTRATED of February 6th, that a printer's error has quite altered the article on papiers cristallé, written specially to answer about the difficulty in fixing the fruit bags. The article says pillow-case pins, instead of pillow-lace pins. The former are of a thick make, quite unusable with papiers cristallé; the lace pins being quite the reverse—long, thin, and sharp.—A. H. C.

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

VIEW OF SCOTNEY FROM QUARRY.

MAKING a good use of accidents in the ground does not enter into the plan of the garden architect, as he calls himself. Yet a most essential thing in garden design is taking advantage of any differences of level or accidents in the ground. We have here one of the best evidences I have yet seen of this in an old quarry at Scotney, giving a view down to the old Castle. It was filled many years ago with

will be succeeded by the Poet's Daffodils and other Narcissi, with some later bulbs to keep up the interest. The Winter Aconite, common though it is, is one of the most charming things we have early in the year.—Ess.

AMONG THE HARDY FLOWERS.

THE CHIONODOXAS.—Were I called on to decide as to the best of the Glories of the Snow I should choose *Chionodoxa Lucillæ*, which appeals to me because of the brilliant blue and white of its colouring, reminding one of the *Nemophila*. *C. gigantea* is fine, no doubt, but I do not care so much for its colour, although that is, I suppose, a question of taste. *C.*

speaks of "amazonian March," with her "sleety arrows." It almost makes one shudder to think of some of our early flowers subjected to that month's hardships. The hand-light is too cumbersome for a small plant. The same may be said of the cloche. I have seen bottomless wooden boxes used with a sheet of glass laid over them, and this is possibly the cheapest way of covering a pet plant. The little continuous cloches do very well, and come next the glass-covered boxes in point of cheapness. They have the advantage over the latter that you are able to have a side view of the flower without uncovering the plant. The sheets of glass which are used by some to throw rain off their plants

Scotney Castle, from the quarry.

Azaleas, and makes a brilliant picture. This is the sort of thing that does not come into the calculations of the man who designs on a drawing-board in straight lines and avenues, and all sorts of facilities to hide the landscape. W.

The Winter Aconite (*Eranthis hyemalis*). This came into bloom with me about January 18th, a few days after writing my note which appeared on page 52. The first flowers to appear were those in a "bulb corner," where the bulbs are carpeted by other things, and where the White Honesty is allowed to sow itself. When the Winter Aconites, the Snowdrops, and the Crocuses are past in this corner they

sardensis is very pretty also, but it is, I think, not so handsome as *C. Lucillæ*. *C. Timolusi* is bright and comes nearer than any of the others to *C. Lucillæ*. I suppose with most of us it is a case of "t'other dear charmer."

PROTECTING EARLY BULBOUS FLOWERS.—It is surely worth while to consider the best way to protect the flowers, so that we may enjoy their beauties as long as possible. Our springs are not too favourable for the early flowers, and much as I dislike hand-lights, cloches, glass-covered boxes, and such like in the flower garden, I fear we must sometimes use them to protect some precious gem which we have just obtained. I think it is Swinburne who

in winter are not of much use for the purpose we have in view.

ASTILBE DAVIDI AND ITS HYBRIDS.—I have seen *Astilbe Davidi* very handsome in a garden, where it was planted by the side of a little stream which flowed through the place. It was the first time I had seen it, and I was naturally impressed by its handsome magenta-rose plumes. The colour is a bit hard, it is true, but the plant is effective when seen with its plumes 6 feet high, as these were. Soon afterwards I saw it in the garden of a friend who had planted it in a dry place. The difference was most marked, as the latter plant looked starved, poor, and unhappy. This and other pink

Asstilbes, to be seen at their best, must have plenty of moisture.

GALTONIA CANDICANS.—It is about time that those who are going to plant the Cape Hyacinth were setting about it when the weather is fine and the ground not too wet. I heard a discussion among some of my friends the other day about its hardiness, and I put the question to an amateur with a long experience of bulbs. I was informed that it was generally (though not invariably) hardy if planted 8 inches deep in well-drained soil. This information is worth passing on, as there are many who would care to try this noble plant if they were likely to establish it as a permanent inhabitant of their gardens.

ASTER THOMSONI.—I like this handsome Starwort, whose large, blue flowers on a plant about 1½ feet high give a border such a charm in summer. It is not troublesome to grow, but it wants to be watched in case the soil becomes too much washed away from the crowns and the plant suffers in winter. More than once I have known this happen.

AN AMATEUR OF HARDY FLOWERS.

VIOLETS.

MORE use should be made of these in the open air garden. We all know what handsome blossoms they produce under frame cultivation, but when they are used outdoors much of the labour necessary in frame cultivation is dispensed with, and I often wonder why such welcome early flowers are not more often seen in the open air. *Viola odorata* being abundant in our hedgerows it is not necessary to plant it, although I know of instances where it has established itself and become a dense carpet of blue, fragrant blossoms such as can be equalled by no alpine plant in January. Nestling at the foot of a sunny wall or at the base of large Lichen-covered tree-trunks, where it catches the morning sun, this little plant is very happy.

It is the stronger-growing varieties which provide us with such excellent material, and wherever a favourable position is at hand we should furnish it with some of the lovely single forms at our disposal. Usually we are recommended to plant Violets on north or shady borders, but this does not always apply; indeed, it is misleading to those who desire an outdoor display early in the year. For this purpose a rather sunny position should be chosen where the plants reap full advantage of what little sunshine there is at this early date. By the latter part of January a bountiful supply of flowers is available, and this can be said of very few plants at this early season.

I grow a nice collection of the best-known single varieties for this purpose, these being planted in various positions, such as a sunny bank or the ledge of low retaining walls, a practice I can strongly recommend, as in this way they flourish and are extremely beautiful. Admiral Avellan is grand for this purpose.

Violets are also used to carpet the ground below climbing Roses and other climbers, where they may remain for two or three years without disturbance; also at the base of pergolas, where they give colour when the things above them are bare. Some have also been planted among Azaleas, where not crowded, and promise well, the Azaleas providing a slight shade in summer and admitting full sun and light in winter. By growing them in this way the trouble of propagating is dispensed with, for they root so freely as to provide an abundant supply of healthy young plants which are available for further extension. If the plants are put out in April where intended to remain a

good supply of flowers will be forthcoming the following season. Leave the runners on the plants, as these will bloom at the leaf-joints. The mingled leaves and flowers of these long growths are very useful for draping vases, etc. One important point in growing these choice flowers is shelter from bleak north-east winds. A change of ground should be provided every few years.

A selection of good single varieties for this purpose would be Admiral Avellan (deep purple), Ascania (rich violet, large), La France (dark violet-blue), Princess of Wales (light blue), Kaiser Wilhelm II. (deep violet, similar to La France), Mrs. Schwartz (deep violet, glazed white), Souv. de J. Josse (reddish-violet, white eye), California (light violet-blue, extra long stems), and Middle. A. Pages (rosy-purple, sweet-scented). E. MARKHAM.

NOTES AND REPLIES.

Michaelmas Daisies.—The time has again arrived when, if good results are wished for, the lifting and division of the stools must be done. The stools first have their labels firmly fixed to them, and are then lifted and placed in a group near by and covered with mats while the border is manured and dug. The soil should not be made too rich for these Starworts, but, at the same time, it must be kept in good heart, otherwise there will be a lamentable failure in regard to the amount and quality of the flowers; likewise the duration of the blooming period, should the season be hot and dry. As the roots appreciate cool and moist surroundings cowshed manure or a mixture of the latter and stable manure is, when it can be had or spared, preferable to the latter alone. Nice young pieces taken from the outsides of the stools are used for replanting. As heretofore, varieties having flowers of different shades of pink and those of a pure white will be largely represented in the border, the best only of the various shades of blue, purple, lavender, and mauve being employed. The front line will be planted with the dwarf varieties alone. The clumps in the mixed borders will be lifted and replanted when the borders are pointed over.

Border Carnations the second year.—In my opinion one of the greatest mistakes made by many cultivators of border Carnations is doing away with the plants after one season's flowering. Perhaps individual flowers may not be quite so fine on second-year plants, but for general usefulness and effect really excellent material is possible. Three-year-old plants (and occasionally four-year-old plants) will yield good results. This I have proved on several occasions. Plants retained a second year will give three to five good spikes while the layer usually gives but one; the plants of three and four years' growth give up to thirty spikes if one cares to leave so many. Where it is intended they should be left, the position ought to be well prepared at the outset by deep digging and the incorporation of plenty of well-decayed manure. Another way of assisting old beds is to fork the surface over in the spring when growth is pushing, and lightly dress with well-decayed manure rubbed through a coarse sieve. Spent Mushroom-bed manure would answer the purpose admirably with the addition of lime or powdered mortar rubble. Where this practice of leaving the plants is followed, layering need be done only every second or third year—unless there be some special variety to increase. The autumn is undoubtedly the best time to plant Carnations, but where this is not possible planting must be attended to in the spring.—C. TURNER, *Highgate*.

INDOOR PLANTS.

SMILAX

(MYRSIPHILLUM ASPARAGOIDES).

THE last of the trails being now too far gone to be of further use, the plants will be cut down and the crowns given a partial rest by keeping them on the dry side and cooler for a few weeks. Before being restarted they will be shaken out and repotted. Although this was omitted last season the crowns pushed up an abundance of growth, but it is doubtful if such successful results would follow if it were again repeated. After being repotted the crowns require a nice genial warmth to give them a start, and if they can be stood on the surface of a plunging-bed matters are still further expedited. When new roots begin to appear round the sides of the balls, and growths are being pushed up, the plants can then be taken back to where the trails are usually trained. For the sake of convenience, when required for use, each growth or trail should have a separate string on which it can become entwined. When detached the trails are then easy to manipulate, and the twine, which should always be green in colour, can, if necessary, be withdrawn at a minimum of time and trouble. Some find it necessary to grow the plants in boxes and prepared borders to obtain successful results, but it is found that with pot culture an abundance of trails for decoration is always available for nine months out of the twelve. The present is a suitable time for raising fresh stock from seed, which should be sown in heat. Both the ordinary *Myrsiphyllum asparagoides* and the miniature-leaved form named *myrtifolium* should be grown, as the latter can often be used where the former is not admissible.—A. W.

NOTES AND REPLIES.

Poinsettia pulcherrima.—In the article on page 20 on this, most of the salient points as regards culture are dealt with, but I missed the reference to growing it in small pots. In the early eighties there was quite a rage for getting the largest heads of bloom in the smallest possible size of pot. To obtain plants that will develop floral bracts 20 inches across in 60-pots by late November, and that will retain their foliage in a healthy state, required great care at all times. The hit-and-miss methods practised in many private gardens at the present time will not produce 20-inch bracts and healthy leaves on plants not more than a foot high; indeed, the tendency of Poinsettias is to grow tall, and then they cannot be considered ornamental. Some growers twist and curl their stems around the surface of the pots, and in this way get dwarf plants with a foil of foliage, making a good setting for their bright bracts to rest upon. It, however, requires care to carry out this successfully. Grown naturally there is, to my mind, nothing that displays their decorative scarlet bracts to such advantage as a bank of Ferns, so arranged that the eye is brought directly in line. Stood on high stages, and having gaunt, thinly leaf-clothed stems, they have no interest. Old plants treated as suggested on page 20, and allowed to produce ten or more shoots, are much more ornamental than young single-stemmed plants.—W. S., *Wills*.

A cool house of flowers and foliage.—A very pretty and interesting arrangement can be made with comparatively hardy plants in quite a cold house. The cost of fuel is a serious matter both to the private gardener and the market man. A very

pretty effect can be had with bulbs, hardy British Ferns, and Grasses in 5-inch or 6-inch pots or boxes. Crocuses and Snowdrops are very bright in the cool house now. Hyacinths, Narcissi, Anemones, etc., are coming on, and the Christmas Rose in variety has been useful and beautiful for some time. A collection of hardy Ferns is as interesting as the tender species, and may include such kinds as *Scolopendrium crispum* and others of the Harts-tongues, *Polystichum angulare proliferum*, *Polypodium cambricum* (Welsh Polypody), *Osmunda regalis* (Royal Fern), *Asplenium Adiantum nigrum* (Black Maidenhair), *Asplenium Trichomanes* (Black Spleenwort), *Lastrea filix mas cristata*, and many others. Some of the Australian Dragon trees (*Dracenas*) and other things from Australia and New Zealand which only require a little shelter in severe weather may be included.—E. H.

Acacia Riceana.—For planting out in a conservatory or glass corridor *Acacia Riceana* deserves more notice than it receives at the present time. Its pendent growths, like those of a Weeping Willow,

wonderful colour, their profusion of flowering, and the ease with which they may be grown account for this. A good many who grow them do so for an early-summer display, and to this end it is well to sow seed presently in heat in a light, friable compost, potting each plant off separately. It is best to grow them on under temperate conditions if it is desired to have the plants in bloom for the longest possible period. For the final potting 5-inch or 6-inch pots should be used, and a mixture of loam and leaf-soil with either rotted cow-manure or bone-meal added.—LEAHURST.

Euphorbia jacquiniæflora.—Few of the winter-blooming stove plants are so showy as *E. jacquiniæflora*. It is naturally rather straggling in habit, and if an attempt is made to pinch the shoots the racemes are shorter and less imposing. I have found it best for cutting to strike half-a-dozen cuttings in each pot, and to grow these on naturally without division or stopping. Each of these will throw a long and handsome raceme, and, should they not be required for cutting, the effect of such potfuls is excellent.—KIRK.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

SAXIFRAGA BURSERIANA GLORIA.

This is one of the gems of its race, invaluable, and certainly unsurpassed at

A group of *Saxifraga burseriana gloria* in the rock garden at Lilford Hall, Oundle.

and in May or earlier its long spikes of pleasing pale-yellow flowers, combine to make a charming feature in the lofty conservatory or corridor. For years there has been a fine specimen in the corridor of the large range of houses at the Edinburgh Royal Botanic Gardens. It comes from Tasmania, and is said by some authorities to be synonymous with *A. setigera*, but, according to the "Index Kewensis," this is not the case, *A. setigera* being referred in that work to *A. undulæfolia*.—Ess.

Rivina humilis.—This is a universal favourite, but, unfortunately, well-grown plants are the exception. This, I think, is attributable to the common practice of growing *R. humilis* in much too high a temperature and in too shaded positions. The result is that the berries fall off at the slightest touch, and the foliage drops prematurely, leaving a semi-bare and straggling plant. This untidy habit forms a great drawback to the plant, but if the conditions are changed success will follow. Let plants be grown in a warm greenhouse instead of the stove, give them as much air and light as possible, and both fruit and foliage will be so firmly attached to the plants that even a vigorous shake will fail to dislodge them.—KIRK.

Schizanthuses.—Few half-hardy annuals have received more attention than *Schizanthuses* during the last few years. Their

this early season of the year. It is the largest-flowered of the *Burseriana* group, and with me the earliest to bloom. Owing to the mild season it is exceptionally early this year, as it commenced to flower early in January. The accompanying illustration is from a photograph taken on January 26th. The plants have had no protection of any kind. To get the best results it should be given a light, gritty loam in full sun, and coolness maintained at the roots. This coolness at the roots is secured by mixing a good proportion of stone chips with the soil and giving a top-dressing of the same on the surface. Good drainage is, of course, essential. When this top-dressing is given, overhead watering is required at much less frequent intervals.

This *Saxifraga* can be easily propagated by division. If a plant is taken up and the soil carefully shaken out it is quite easy to cut it up into ten or twenty pieces, each with ample roots to support it. If these are potted up firmly in a light compost and kept moist and close for a week or so they rapidly make good plants.

F. W. G.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM FEBRUARY 3RD.—*Andromeda japonica*, *A. floribunda*, *Berberis* (in variety), *Ericas* (in variety), *Alders*, *Witch Hazels* (in variety), *Garrya elliptica*, *Parrotia persica*, *Yellow Jasmine*, *Winter Sweet*, the *Cornelian Cherry*, *Daphnes* (in variety), *Coronilla glauca*, *single Camellias*, *Forsythia suspensa*, *F. spectabilis*, *Edgeworthia chrysantha*, *Cydonia japonica*, *Rhododendron præcox*, *R. Nobleanum*, *Violet Cress*, *Snowdrops* (in variety), *Violets* (in variety), *Snowflakes*, *Tufted Pansies*, *Cyclamen Coum*, *Anemone coronaria*, *A. Hepatica* (various colours), *Anemone blanda*, *Primroses*, *Tritelecia uniflora*, *Saxifraga apiculata*, *S. sancta*, *Hellebores* (in variety), *Lithospermum rosmarinifolium*, *Ficaria grandiflora*, the *Lesser Celandine*, *Crocus speciosus* (in variety), *Narcissus pallidus præcox*, *N. Tazetta*, the *Bitter Vetch* (*Orobas vernus*), *Aconites*, *Blue-eyed Mary* (*Omphalodes verna*), the *Scarlet Windflower*, *Viola gracilis*, *Algerian Iris* (*I. unguicularis*), *Wood Anemone*, *Winter Heliotrope*, *Scilla sibirica*.

WORK OF THE WEEK.—The numerous catalogues which arrive at this season of the year are often so bulky that it is impossible to go carefully through them all, except for novelties, of which a good one only appears at rare intervals. They have been looked over and the usual seeds ordered, including some of the best and most distinct annuals. The removal of dead foliage from plants in the mixed border has been attended to, as many of these are on the move. *Spiræas* of the Meadow Sweet order which were too coarse for this part of the garden have been transferred to the waterside and a group of China Roses on their own roots has been planted in their place. China Roses in four varieties have been planted in a bed in the flower garden where they will be partially shaded and protected by a high wall, and where it is expected that the flowers will retain their beauty for a longer period than those exposed to sunshine the whole day. A suitable ground-work will be provided later. Some attention has been given to the clearing up and repairing of walks where these had shown signs of wear and tear. More tripods have been prepared and fixed to allow the work of pruning, tying, and forking over of the surface to be pushed along. Climbing plants are growing, in some cases, to an alarming extent, and, if not attended to at once, will be much damaged when getting them into position later. A quantity of *Erica vulgaris* Searlei, having become rather worn out, has been destroyed to make room for a group of *Berberis concinna* which had come to hand. A few plants already on the place were lifted, and helped to make up the group. *Clematis chrysocoma* has been planted at the base of a recently-erected post and rail fence. Herbaceous *Phloxes* in considerable variety which had been in position for three years have now been lifted and replanted on a prominent and sheltered piece of ground which had previously been well manured. Large plants were split in two by means of two forks placed back to back. This is a much better method than cutting through with a spade, scarcely a crown being damaged. *Erica mediterranea hybrida* has been planted as a groundwork to *Azaleas* where thinly disposed. The soil is heavy and sticky, and it will be interesting to note their progress in such. A large number of seedlings of *Clematis viticella* which were raised here has been put out at intervals

along a hedge of Japanese, Scotch, and other Roses; also on Holly hedges and a few in a neighbouring wood at the foot of Rhododendrons, Laurels, or any other likely support near the rides. E. M.

Succer.

SOUTHERN COUNTIES.

Early vinery.—As soon as the growths are sufficiently advanced for the finest bunches to be seen the surplus are best dispensed with. A rise of temperature from 55 degs. to 60 degs. by day, and from 50 degs. to 55 degs. by night, with a corresponding increase of moisture, will induce the bunches to lengthen out quickly and allow of the laterals being stopped at the second leaf beyond the bunch. Sub-laterals as they appear are rubbed out between the rods and bunches, but beyond the latter are stopped at the first leaf, and the same when they break and produce new growths. Tying down of the laterals to the trellis, as nearly as possible at right-angles to the rod, which has to be done by degrees, is generally attended to early in the morning. Very few accidents then occur in the way of the laterals snapping off at the base when the sun bursts out and increases the sap flow. Ventilation has to be done with care and judgment when the wind is in the north or east. The manipulation of the valves regulating the supply of artificial heat is another matter which, owing to the present cost of fuel, has to have very careful consideration. Until the Vines are approaching the flowering period the above-named temperatures will be strictly adhered to.

Pot Figs.—As soon as from five to six leaves have developed, the points of the shoots must be pinched to aid the more speedy swelling of the fruit. As the roots are now very active their requirements in regard to supplying them with liquid stimulants have to have close attention. A further top-dressing of the same kind of material as that last afforded is now required, employing the same device to hold it in place as before. Until the fruits begin to flower copious syringing of the foliage is a necessity twice a day, while the damping of floors has to have frequent attention.

Planted-out Figs.—These require the same treatment in regard to pinching of the shoots. Watering, until the trees become fully clothed with foliage and the fruits fast developing, does not yet call for frequent attention, but at the same time care is necessary, otherwise the first crop may be lost should the border be allowed to get dry. A free use of the syringe both in the morning and at closing time is admissible until the fruits come into flower, when, for the time being, direct syringing must cease. Until this stage is reached the temperatures both for these and pot trees should not exceed 65 degs. by day and 60 degs. by night. For the latter a bottom heat of 75 degs. to 80 degs. must be regularly maintained.

Half-hardy annuals.—The number of these has this year, with a view to saving labour later on in the way of pricking off into boxes, been much reduced. A few things, such as Alonsoa, dwarf Larkspurs, and Lobelia, which cannot be dispensed with, will now be sown and placed in warmth until the seedlings appear, when they will be moved to a cooler place.

Sweet Briar hedge.—This is now undergoing the usual pruning and tying into shape. Last season these Briars flowered freely and a quantity of hips, which proved very ornamental through the autumn and winter, resulted. As they are now much discoloured they must be cut off. After the hedge is put in order the

border will have the verges trimmed and the soil pointed over after dressing the surface with manure.

Shrub beds and borders.—These will now be cleaned, as the position of bulbs can now be seen. The leaves which have been blown among the shrubs will, where possible, be left to be dug in. Where the Dogwood is used for winter effect it will be cut close down to the ground. The annual growths resulting from this method always take on a vivid colour as winter approaches, and prove very effective when viewed from a distance. The staking of Brooms, Tree Lupins, etc., will be attended to beforehand.

Loganberries.—A new trellis, considerably higher than the old one, has been erected for these. This will enable a greater length of cane being left than formerly, consequently a larger yield of fruit can be confidently looked for. Last season the majority of the fruits were bottled whole, with very successful results. The experiment will be repeated this season on a large scale.

Summer Raspberries.—These will now be finally thinned, tied, and then tipped just above the level of the top wire of the trellis. The canes are robust and well ripened, and sufficiently abundant to allow for a good selection being made. String is used to secure them to the wires, as raffia is apt to decay before the season is over. Where the various insect pests to which Raspberries are liable have been troublesome, care should be taken to cut every piece of old wood on the stools level with the ground, gathering up the prunings and freeing the surface of pieces of decaying wood; also stones or anything likely to form a harbour for them at certain stages of their existence.

Autumn Raspberries.—These must now be cut down to within 1 inch or 2 inches of the ground, and the border afterwards mulched with decayed manure.

Parsnips.—When the surface is dry, seed will be sown on ground which has not been manured since last spring. After so much rain the soil will require pricking up to a couple of inches in depth with a digging fork. The seed will be sown in shallow drills drawn 1 foot apart. Where specimens for exhibition are required, and they cannot, owing to the staple being unsuitable, be produced under ordinary conditions, the seed should then be sown in stations previously prepared by boring with a bar holes at least 3 feet in depth and 9 inches apart, in rows 1½ feet asunder, and filling them with fine light compost. This should be made firm. A few seeds sown in each hole suffice, and when germination has taken place and the plants become sufficiently advanced for thinning to be done leave the strongest at each station.

Cauliflowers.—Seed of an early, also a summer, variety will be sown, raised, and subsequently treated in the same way as that mentioned for Brussels Sprouts. Plants in frames need all the air possible in mild weather and the soil stirred between them. When fine, the sashes may be drawn off altogether. The chief thing to be aimed at now is to get the plants hardened as much as possible, so that when transferred to handlights a little later they will experience little or no check.

Parsley.—Seeing that this has not wintered at all well provision has to be made for coping with a possible shortage later in the season by making a good sowing in boxes now and raising the plants in slight warmth. When properly hardened off the largest of the plants will

be ready for planting out in lines in a sheltered place early in April. The remainder will then be planted later more in the open. Plants grown by this method give far better returns than when sown in the usual way. If planted from 9 inches to 12 inches apart each then develops into a specimen and yields a quantity of leaves. The variety preferred here is the Giant Curled. Parsley makes an ornamental edging to fruit borders and similar places during the summer. For this purpose one of the finer-leaved and dwarf varieties answers best.

Lettuces.—The remainder of the plants of Hardy White Cos in the seed-drills, where they have stood all the winter, should now be transplanted in rows 1 foot apart and 9 inches from each other, in light, rich soil. Those set out at the foot of walls having warm aspects need the soil lightly stirred between them. The few losses sustained during the winter can be made good with plants drawn from the above-named seed-drills.

Brussels Sprouts.—As these require a long season of growth seed must now be sown in gentle warmth to furnish the plants which will be expected to yield an autumn and early winter supply of sprouts. The seed is best sown thinly in boxes, which prevents the plants becoming drawn previous to pricking them out into a frame stood on a bed of fermenting material consisting for the most part of leaves. A sowing in a sheltered nook outdoors will be made at the same time.

Celery.—A small sowing of an approved white variety must now be made. The plants in this case will be for an autumn supply. For main crop purposes sowing will be deferred till the first week in next month. Thin sowing is essential, and after germination takes place a light position must be accorded the plants to keep them sturdy until they are large enough for pricking out into a hot-bed frame.

A. W.

MIDLAND COUNTIES.

Strawberries.—The fruits on early plants will now be thinned, leaving four to six berries on each plant. The fruiting spray is supported by a small forked twig in order that it may be better exposed to sun and air. At this stage the plants may be afforded an atmospheric temperature of 65 degs. at night and 75 degs. by day, provided plenty of atmospheric moisture is given. Attend carefully to watering, giving liquid-manure or soot-water at every alternate application.

Early Vines have made sufficient growth to determine which shoots to leave and which to remove. On bright days, when the weather is mild, the Vines are syringed gently and the paths and surroundings damped ^{at} time. The admission of fresh air to the houses during the early part of the year requires to be done with great care, the foliage at this season being very tender and soon injured. A change of air is necessary at least once a day to ensure the proper development of fruit and foliage, but it must be admitted in such a manner that the temperature of the house will not be suddenly lowered or cold draughts created thereby. Ventilation must be gradual, and it is advisable on fine days to ventilate early rather than wait until the atmosphere becomes excessively hot in the house. Full advantage should be taken of the sun's heat by closing the house early in the afternoon. No harm will follow if the thermometer runs up 10 degs. or 15 degs. through this early closing.

Peach-trees which have been detached from the walls in order to retard the

blooming to as late a date as possible must now be pruned and trained, as the buds are swelling fast. In regard to the pruning, very little remains to be done, with the exception of the removal of a branch or shoot to avoid overcrowding. When the training of the trees is completed the means employed to protect the trees from frost will be got in readiness. I find two or three thicknesses of fish-netting placed on poles in front of the trees sufficient to ward off several degrees of frost. Spraying is now completed, and many trees show signs of bursting into growth. These will need protection should severe frost occur.

Herbaceous Phloxes.—There are now so many beautiful varieties of Phlox decus-

Cannas.—The tubers which have been stored during winter will now be cleaned and separated, selecting the most promising crowns, which are usually to be found on the outside of the clump. These are planted in boxes of leaf-mould and placed in a gentle heat. When growth has commenced they will be potted up into 5-inch and 6-inch pots. They do not require much water until growth is well on the move. When they have reached a suitable size they will be hardened off gradually. It is useless to expect success with Cannas unless the plants are of large size and in good condition at the time they are planted out.

Cuttings of Pelargoniums, and which

Pansies, etc., are already in flower. The various species and varieties of bulbs are equally early. Beds containing spring-flowering plants should have the surface stirred as frequently as necessary, taking care to avoid damaging any bulbs which are coming through the soil.

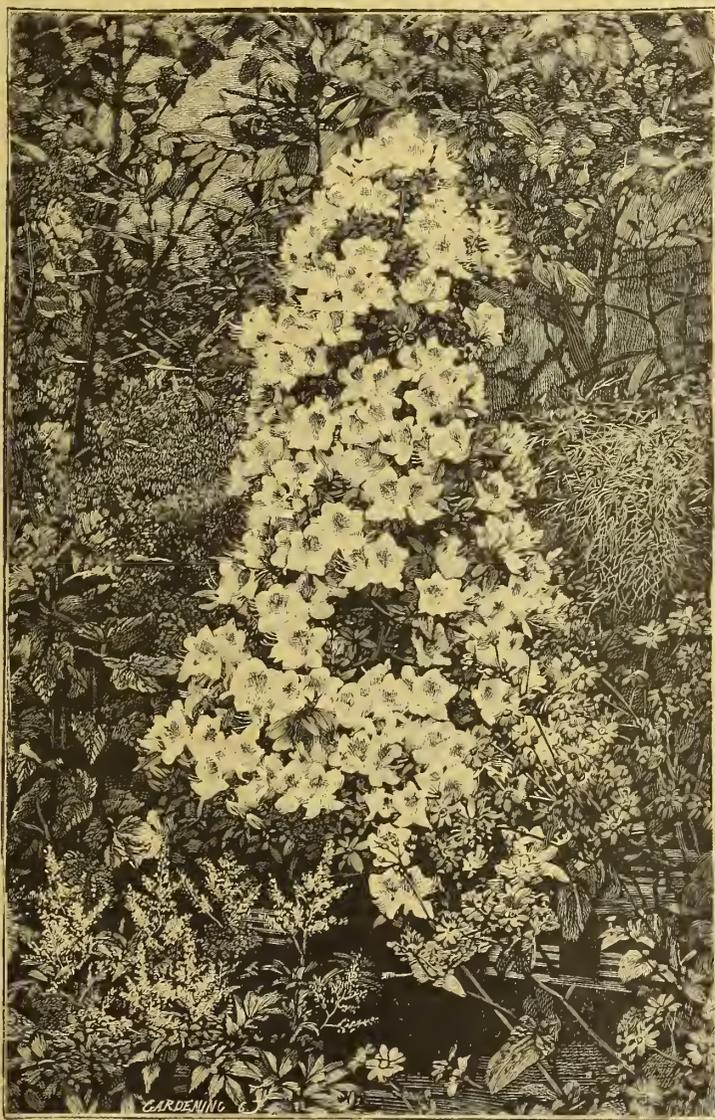

Onions require a long season of growth to ensure fine, well-ripened bulbs. I, therefore, place more importance on getting the main Onion crop sown earlier than any other. The ground intended for this crop having been trenched and manured in the autumn, the bed only requires a dressing of soot lightly forked in and making the surface as fine and level as possible. Should a storm of rain come on whilst this is being done it is better to leave it until the surface is dry than to tread the ground when wet. During unsettled weather it is sometimes necessary to fork the ground three or four times to get it into a good condition for sowing. Nothing is more detrimental to land intended for the sowing of small seeds than trampling on it while it is wet. When the surface has been made firm and raked until the soil is quite fine, drills may be drawn 15 inches apart and 1 inch deep. Sow the seeds thinly and cover them with care. The surface may then be lightly trodden, and levelled with a wooden rake, taking care not to disturb the seeds. If the seeds are sown thinly very little thinning will be necessary in the case of the main crop, as bulbs of a medium size are more serviceable and keep better than very large ones. A light dusting of soot should be frequently applied, choosing showery weather.

Leeks.—Another small sowing will be made in heat, and seedlings of earlier sowings pricked off into boxes as they become ready. F. W. GALLOP.

SCOTLAND.

Ferns from spores.—This is a suitable time for sowing the spores of Ferns. In some houses the commoner varieties reproduce themselves freely from self-sown spores, but it is just as well to make a sowing of the better sorts. A light, sandy compost, with, if possible, the addition of a little peat, is best for this purpose. Make the surface level, and after sowing do not cover the spores. If the pans are put into the propagating-case and the soil kept regularly moist and shaded germination soon follows. Seedling Ferns are always better than pieces obtained by division of old plants.

Autumn-sown annuals.—In the course of the week a look over was given to annuals sown during the month of September. These have done wonderfully well, and when the soil becomes a little drier the seedlings will be finally thinned. Some singling was done during October, but it is always considered advisable to leave the seedlings rather thickly until February, in order that possible damage by frosts or slugs during the winter may be allowed for. Some annuals are more suitable for autumn sowing than others. Among these the showy Papaver umbrosum is outstanding. The plants are much superior and bloom much more freely, and over a longer period, than when sowing is deferred until March. Other good things include Saponaria calabrica, Collinsia bicolor, Virginian Stock, Candytuft, and the useful Eschscholtzia californica. Mignonette does not, in these gardens, adapt itself to autumn sowing, the plants apparently perishing from winter rains, which are at times excessive. A light dusting of soot will be afforded when thinning is completed, this

Pyramidal-trained Azalea.

sata that in gardens where space will allow they are worthy of a border to themselves. The soil for Phloxes should be liberally dressed with well-decayed farmyard manure. The best plan in planting is to make groups of each variety, arranging the clumps in an irregular fashion, employing six or seven plants in each clump, and planting them firmly at a distance of 2 feet 6 inches apart. These Phloxes may be increased readily from cuttings or division. Quite small pieces if potted up into 3-inch pots, placed in a cold frame, and kept moderately close for a time, will soon grow into good plants.

Delphiniums may also be propagated now by detaching the side shoots and potting them up into 3-inch pots as advised for Phloxes.

are still in boxes, should be potted singly without delay and placed in a warm-house for a time.

Propagating.—All kinds of soft-wooded plants may now be propagated. Most of the subjects root readily, especially if bottom-heat is provided. Heliotrope and Ageratum we require in considerable quantities. Salvia splendens and its varieties may be propagated either from seed or cuttings. Scarlet Queen and Zurich are both fine varieties for planting out-of-doors in the summer. Strong, healthy plants, grown without a check, provide a display of flowers soon after they are planted, and continue until frost arrives. Owing to the exceptionally mild weather, all spring-flowering plants are very forward; many Aubrietias, Saxifrages,

not only checking slugs but stimulating the growth of the seedlings.

Pollarding.—An old avenue of Plane trees which divides the upper from the lower garden is in the course of being pollarded. This is done every third or fourth year, and the resulting growths make passable Pea-stalks, and the butts of the thicker growths are useful for Dahlia stakes or for hardy plants, while the thinner tips are of value as supports for Chrysanthemums. Of course, they are only useful for a single season, as the wood soon rots, but in the course of a year many of the stronger growths are again available.

Crinums and Vallotas.—These useful bulbous plants are again starting to grow, and a little attention was given to their needs in the course of the week. In the case of Crinums the surface soil among the thick and fleshy roots was removed with a pointed stick, a mixture of good loam enriched with a little chemical manure being afterwards worked carefully in. Similarly the soil was removed for an inch or two from the top of the pots of Vallotas and replaced by a rather more sandy mixture than that given to Crinums. Both will now be placed in slightly heated pits, where they will remain until the outside temperature becomes sufficiently mild to permit of their being removed to an unheated house. During the summer the Vallotas will be stood in cold frames until they show signs of coming into bloom.

Old plants of many things are gradually being got rid of as their period of effectiveness terminates. There are many plants which can quite easily be grown to a serviceable size in the course of a season, and such young pieces are always to be preferred to older plants. Cuttings of plants about to be discarded are taken in sufficient numbers to provide for possible requirements with a fairly good margin before the old pieces are destroyed.

Greenhouse plants.—The busy time in connection with the propagation, potting, and repotting of greenhouse plants has again arrived, and during the week a good deal of progress has been made. A good number of Zonal Pelargoniums was moved on for autumn blooming, from 5 inch to 7-inch pots, and a considerable quantity of autumn-struck cuttings was potted off from the cutting-boxes into 4-inch and 5-inch pots. The former batch was put into heated pits where they will remain for a time, while the latter are, for the present, accommodated on shelves in a moderately warm greenhouse. Although their value is undeniable, one sometimes gets rather tired of these plants, and other things are grown to some extent to give variety. Among these, double-flowering Petunias are valuable. The more moderately-sized varieties are again preferred, for it was found that exceptionally large-flowering sorts were not only less free, but their blooms were very liable to damp off before expanding fully. A sufficient number of cuttings has been put in, and should more be needed the tops of these will in their turn be used at a later date. Cuttings of the once generally grown *Diplacus glutinosus* were also put in. This last can be grown on to form good pieces in 8-inch pots in the course of six months. It is liable to be attacked by black aphid, for which a watch will be kept. A dozen or two of Hydrangeas, which last spring carried single blooms, were potted on into 8-inch pots. As these plants will occupy the same pots for a year or two the potting was done very firmly. Fuchsia cuttings were taken, and a quantity of cuttings of different kinds of

the various edging plants, including *Campanula isophylla* and *C. i. alba*, was put in at the same time. A small batch of eighteen special double-flowering Begonias was started in a box upon Cocoa-fibre. When some growth is made these will be transferred to 6-inch, and finally to 10-inch pots. A useful plant for cool greenhouse work is *Mimulus cardinalis*. *Abutilon Savitzi* strikes readily at this time, and cuttings of this and *Coprosma Baueriana* were put in in small quantities. All the available shoots of *Salvias*—chiefly *S. Pride of Zurich* and *S. Glory of Stuttgart*—were put in, these being intended for use in the open. A few plants of *Aloysia citriodora* were introduced into heat for the production of early cuttings.

Work outside has again been interfered with by rain during the week. Broad Beans for early planting were sown in boxes. These Beans transplant readily, and may go out as soon as the soil is sufficiently dry. After such a prolonged spell of wet one is a trifle impatient and apt to go upon the soil rather too soon. It always pays in the end to exercise restraint in this respect, for if the soil is "poached," as we term it, at the beginning, it is difficult to get it into good order later. W. MCGUFFOG.

Balmæ Gardens, Kirkcudbright.

ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 8TH, 1916.

At the annual meeting of the Society there is always a good gathering, and this year, notwithstanding the abnormal conditions prevailing, exhibitors came from far and near. Forced flowering shrubs were the outstanding feature. Alpines, too, were in strong force from many sources, and few plants appeal more forcibly at this early season. Among winter Crocuses were some of especial interest and giving touches of colour not seen elsewhere. The new *Primula malacoides* Rose Queen was the admiration of all, the larger flowers, distinct colouring, and more compactly-formed spikes placing it in the front rank of novelties. Orchids and other greenhouse plants were freely shown.

FLOWERING SHRUBS.

Messrs. R. and G. Cuthbert, Southgate, arranged a very fine group, for which a gold medal was awarded. Lilacs in both standard and bush form and white and coloured varieties were in abundance and of exceptional merit. *Azalea mollis* and its near allies were effective both in the margin and when associated with the white-flowered *Staphylea colchica* and bronze-leaved *Acers* in the groundwork. *Pyrus Scheideckeri* and *P. floribunda* *superba* gave warmth of colour not afforded by anything else, while *Wistaria sinensis* and the goblet-like cups of the *Magnolias* rendered the whole the more effective and imposing. *Forsythias* and *Laburnums* were freely employed, a background of Palms supplying greenery of a graceful and useful kind.

Mr. L. R. Russell, Richmond, had a showy table of Indian *Azaleas* in much variety, the 18-inch-high examples with well-proportioned heads a mass of flowers. For the greenhouse at this time no plant is more effective than these. A group of distinctly compact-growing plants of *Rhododendron præcox* was also remarked.

Messrs. J. Cheal and Sons, Crawley, had cut and other shrubs in variety, *Cydonia Simmonsii*, *Lonicera Standishi* (white, fragrant), *Rhododendron præcox*, *Daphne Mezereum* in variety, and *Forsythia intermedia densiflora* being some of the more attractive.

Messrs. Robert Veitch and Sons, Exeter, staged superb flowers of the richly-

coloured *Magnolia Campbellei*, together with a few blooms of *Camellia magnoliæ-flora* of delicate flesh-pink tone.

HARDY FLOWERS AND ALPINES.

Messrs. Waterer, Sons, and Crisp, The Arcade, Liverpool Street, E.C., had a most attractive and effective exhibit in this section. The alpines were in colonies, such important things as the "Satin Flower" (*Sisyrinchium grandiflorum*), *Saxifraga Cherry-trees* (true, a fine, distinct yellow), *S. Boydii alba*, *S. oppositifolia splendens*, and the yellow-flowered *S. Mrs. Leng* revealing both their worth and their garden utility—the only sensible way of exhibiting them. A dainty mauve-coloured *Viola*, most probably a *cornuta* variety named *Lady Crisp*, was also on view.

Messrs. William Cutbush and Sons, Highgate, N., had *Tulipa Kaufmanniana*, *Soldanella alpina*, *Iris alata*, *I. sindjarensis*, and *I. reticulata Krelagei*.

Messrs. Tucker and Sons, Oxford, had delightfully-flowered examples of *Saxifraga marginata*, *S. macedonica* (yellow), *S. dalmatica* (white, not unlike *S. scardica obtusa* in flower), *S. Paulinae*, *S. Kyrilli* (a pair of superb yellow-flowered sorts), together with *S. Striburyi* and *S. Bertoloni*, both reddish-flowered. Some good *Lenten Roses* were shown.

Mr. Amos Perry, Hardy Plant Farm, Enfield, brought a fine collection of the hardy evergreen *Polystichum ferns* in goodly specimens. Pans of *Shortia uniflora grandiflora* and some beautiful plants of *S. u. g. rosea* showed the value of these gems of the hardy world.

Messrs. T. S. Ware, Limited, Feltham, had an extensive table of hardy things, chiefly in pans, *Saxifrages* being largely in evidence. Of these *S. Faldonside*, the queen of the yellows, was well shown, *S. Boydii* (also yellow), *S. oppositifolia major* (a good red sort), with white and yellow *S. apiculata* being also freely displayed. *Morisia hypogæa* (yellow-flowered) was particularly well done. *Lenten Roses* in variety were noted.

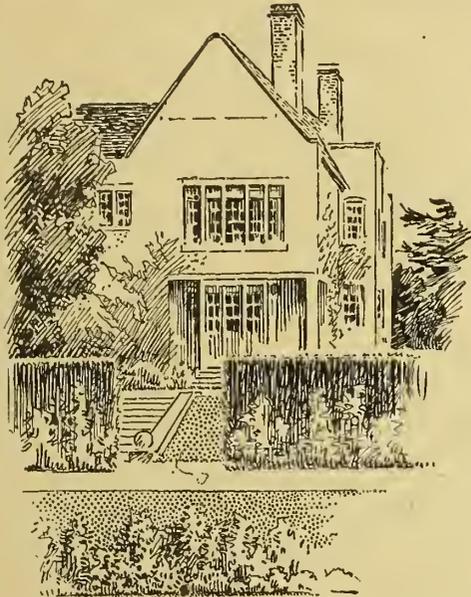

Mr. G. W. Miller, Wisbech, had *Christmas Roses*, *Polyanthus*, *Hepaticas*, *Saxifrages*, *Giant Daisies*, and the like.

Messrs. Barr and Sons, Covent Garden, W.C., showed many things, none more valuable, however, than a batch of *Iris unguicularis* in the cut state. Groups of *Saxifraga Mrs. Leng* and *Elizabethæ* (yellow), *S. Burseriana Gloria*, *S. B. magnifica* (white) were also telling. Choice Crocuses included *C. triflorus Lemon Queen* (a great beauty), *C. Tommasinianus*, and *C. suaveolens*, virtually a light-coloured replica of the last. *C. Imperati* and *C. aureus* were others of merit in a goodly lot. *Lenten Roses* and the diminutive *Narcissus minimus* were also on view.

Mr. G. Reuthe, Keston, also showed charmingly-flowered masses of *Crocus* species, *C. Imperati præcox*, *C. I. longifolius* (a showy form), *C. aureus*, and *C. aeriis* being among the number. *Saxifrages* included *S. latina* (red), *S. Kyrilli* (yellow), *S. Paulinae*, *S. Faldonside*, *S. marginata*, and *S. Griesbachii*.

Mr. Clarence Elliott, Stevenage, showed in good form and some quantity *Saxifraga Obristii*, *S. Burseriana Gloria*, *S. Boydii alba*, and *S. scardica obtusa* (all white-flowered) among the most valuable of the early sorts. The new pink *S. Irvingi* was also on view.

Messrs. Whitelegge and Page, Chislehurst, had the fine silvery *Saxifraga calabrica* in quantity. It is likely to prove one of the indispensables of the race. Cecil Davies is another silver novelty. *S. coriophylla* and *S. Elizabethæ* were excellent.

GARDEN ECONOMY

RREAL Garden Economy lies in not only utilising every atom of space but in making quite sure that the seeds you plant are **LIVE** seeds that will produce the prolific crops your labour entitles you to expect.

Don't wait until the end of the season to find this out—make certain now by planting Eckford's seeds, which are specially selected and of the finest quality you can buy. The following collections of seeds will help you to avoid the disappointment of a poor, weedy-looking garden.

Genuine Eckford Seeds can only be obtained direct from Wem. No agents are employed.

SPECIAL SWEET PEA COLLECTIONS FOR 1916.

VILLA "A" COLLECTION.
50 Splendid Varieties, 25 seeds of each, exquisite for garden effect and cutting. All free flowering and strong. A fine range of colour.
Price 10/6, post free for cash.

VILLA "B" COLLECTION.
24 Varieties. A splendid range of colour for garden effect and cutting. 50 seeds of each.
Price 5/6, post free for cash.

EXHIBITOR'S "A" COLLECTION.
40 Splendid Waved Varieties. This collection includes a half packet of each of 20 Novelties. The number of seeds, other than Novelties, will be 20. This is splendid value.
Price 15/6, post free for cash.

VILLA "C" COLLECTION.
12 Varieties. A splendid range of colour for garden effect and cutting. 50 seeds of each.
Price 2/9, post free for cash.

VILLA "D" COLLECTION.
12 Varieties. The same as Villa "C" exactly, only 25 seeds of each variety.
Price 1/6, post free for cash.

EXHIBITOR'S "D" COLLECTION.
12 Splendid Waved Varieties, excellent for any purpose, fine for exhibition. 12 seeds of each.
Price 2/9, post free for cash.

We also send a specially-written Booklet on the Culture of Sweet Peas FREE with each Collection.

A VEGETABLE GARDEN FOR 6/6

ECKFORD'S IDEAL COLLECTION OF VEGETABLE SEEDS. Carriage Paid for Cash.

This Special Collection of Vegetable Seeds is put up for the purpose of letting everybody test for themselves ECKFORD'S PURE AND HIGH-CLASS SEEDS. The quantities are sufficient for Ordinary Gardens, Allotments, etc., and contain the following:—Four half-pints of Eckford's Pedigree Culinary Peas for succession; half-pints each of Broad Beans, Dwarf French Beans, and Scarlet Runners; and liberal packets of the following small seeds: Beet, Borecole, Broccoli (three varieties—early, medium and late), Brussels Sprouts, Early Cabbage, Pickling Cabbage, Savoy, Carrot, Early Cauliflower, Celery, Cress, Ridge Cucumber, Lettuce (two varieties), Mustard, Onions (two varieties), Parsley, Parsnip, Radish, Tomato, Garden Turnip, and Vegetable Marrow.

The above are all excellent kinds—fine for exhibition. If pints of Peas and Beans are required instead of half-pints, the price of the Collection will be 9/6 CARRIAGE PAID.

We include, free, a specially-written Booklet on Vegetable Culture for the Amateur.

For places abroad the Ideal Collection will be 8/6 and 11/6 respectively, post free for cash.

Eckford's CULINARY PEAS.

If you have never tried Eckford's Culinary Peas, do so now. They are heavy croppers and the flavour is right. All seeds are carefully hand-picked.

- Collection A**—4 pints of Eckford's Culinary Peas in sealed packets for complete succession .. 3/9
- Collection B**—6 pints of Eckford's Culinary Peas in sealed packets for complete succession .. 5/6
- Collection C**—9 pints of Eckford's Culinary Peas in sealed packets for complete succession .. 8/6
- Eckford's Best of All Runner Beans**, a grand new variety, some pods measuring 12 inches or more in length, of excellent cooking qualities, and a very free bearer .. per quart 2/6
- Eckford's "Early Gem" Carrot**, a splendid stump-rooted variety, quality excellent, very tender, almost without core, grand for exhibition .. per oz. 8d.

An ECKFORD FLOWER GARDEN for 5/-

Post Free for Cash.

Eckford's Ideal Collection of Floral Beauties contains:—

- 6 Grand Varieties of Eckford's Giant Sweet Peas, separate and named.
- 3 packets Choicest Asters, fine separate colours.
- 3 packets Choicest Double Ten-week Stocks.
- 2 packets Fine Ornamental Grasses, for mixing with cut flowers.
- 1 packet of each of the following **twelve** Hardy Annuals, all of which may be sown in the open. The culture is given on each packet:—Calliopsis for cutting, Hyacinth-flowered Candytuft, Annual Chrysanthemum, Eschscholtzia (New Shades, mixed), Godetia (New Shades, mixed), Larkspur (Fine Shades, tall for cutting), Lupinus (Fine Crimson and White), Mignonette, Nasturtium (tall, for wall or trellis), Nigella (Blue), Shirley Poppy, and Scabious (Charming Colours).
- 1 packet of each Half-hardy Annuals as follows. The culture is given on each packet:—Eccremocarpus (fine climber for trellis or arch), Lobelia, Eckford's Prize Marigold, Nicotiana (Night-scented), Salpiglossis, and one Schizanthus Retusus.
- 1 packet of each Hardy Perennials as follows:—Anthrinum (Choicest New Art Shades), Aquilegia (Eckford's Long-Spurred), Canterbury Bells, Eckford's Choice Single Wallflower, and one packet of Eckford's Choice Fancy Pansy.

5/- post free for Cash with order. For places abroad, 5/6. This is part postage.

AN ECKFORD FLOWER GARDEN FOR 2/6.

Eckford's Ideal Collection of Floral Beauties for Smaller Gardens contains:—

- 1 packet of each of the following Choice Flower Seeds:—Mixture of Giant Sweet Peas (Waved and other choice varieties), Choicest Mixed Asters, Choicest Mixed Ten-week Stocks, Ornamental Grasses for mixing with cut flowers, Calliopsis, Annual Chrysanthemum, Cornflower (Blue), Eschscholtzia (New Shades, mixed), Godetia (New Shades), Larkspur (fine tall for cutting), Lupinus (fine Crimson and White), Lobelia, Prize Marigolds, Mignonette, Nicotiana (Night-scented), Nasturtium (tall for wall or trellis), and Eckford's Choice Single Wallflower.

2/6 post free for Cash with order.

For places abroad, 2/9. This is part postage.

FREE Send a Post Card to-day for large Illustrated Catalogue. It gives all particulars of the **NEW SWEET PEAS FOR 1916**, and contains a full list of **ALL FLOWER and VEGETABLE SEEDS** necessary for your garden.

HENRY ECKFORD, F.R.H.S.,

Seed Grower and Specialist,
Dept. 64, WEM, SHROPSHIRE.

Eckford's
Pedigree SEEDS

Mr. J. J. Kettle, Corfe Mullen, Nr. Wimborne, surpassed himself by his exhibit of Sweet Violets, a rare and beautiful mass of colour fragrance, and variety. Frame and field grown examples of La France demonstrated both colour differences and size, the field-grown giving the finer colour, the other method the larger flowers. Jamie Higgins (mauve), Swanley White, Mrs. Kettle (silvery-mauve), and Coleroonan (deep Parma-violet blue) are all double sorts, though but a few from out of a sumptuous whole.

Mr. M. Prichard, Christchurch, again brought an extensive assortment of alpinas, such Saxifrages as Griesbachi, S. Burseriana Gloria, S. Elizabethæ, and S. Faldonside being noted among others. Erica carnea rosea was of a good and distinct colour. Lenten Roses were interesting—some beautiful. Soldanellas, too, were charming.

GREENHOUSE PLANTS.

Messrs. Jas. Carter and Co., Raynes Park, showed *Primula malacoides* Rose Queen, one of the outstanding attractions of the meeting. From a background of brownish drapery the myriads of rosy-lilac spires stood out clearly and well, the colour, assisted by the light above, showing to perfection. Obviously a much-to-be-desired novelty.

Messrs. H. B. May and Sons, Limited, Edmonton, showed an excellent strain of *Cyclamen latifolium* Giant White. *Cineraria* Feltham Blue is rich and of decided colour.

Messrs. H. Cannell and Sons, Eynsford, Kent, had a brilliant lot of winter-flowering Zonal Pelargoniums, Firefly being an uncommonly good novelty. Another of distinction and merit is the rich orange-scarlet Maxime Kovalesky. King Victor, too, was very fine.

Forced Narcissi in variety in bowls of fibre came from Messrs. R. H. Bath, Limited, Wisbech, the collection including Henry Irving, Bath's Flame (a fine incomparabilis), The Queen, Golden Spur, and *odorus rugulosus* fl.-pl. Cut specimens of Brilliance, a giant yellow incomparabilis 4 inches across with richly-coloured cup, formed, however, the greater attraction. It is superb; as a forcing sort, probably unique in its set.

Messrs. Blackmore and Langdon, Bath, showed some superbly-grown *Cyclamens*, including Salmon King, Salmon Pink, Brilliant, and Giant White. *Begonias* of the fibrous-rooted set were in several varieties. Pink Beauty and *Virginalis* were two of them.

The Marquis of Ripon, Coombe Court, Kingston Hill (gardener, Mr. T. Smith), sent Tulips and Lachenalias, together with forced shrubs.

Messrs. Sutton and Sons, Reading, had many well-flowered examples of their *Papilio* *Cyclamen* Superb White Fringed, the plants vigorous and freely-flowered.

Mr. R. Mond, Coombe Bank, Sevenoaks (gardener, Mr. W. Hall), contributed a big lot of *Freesia refracta* alba, the well-flowered bulbs quite an attraction.

CARNATIONS.

Messrs. William Cutbush and Sons, Highgate, N., showed their new perpetual-flowering *Malmaison* Sabina, a finely-proportioned variety of rich scarlet colour. Lady Ingestre, one of the best pinks, was well presented.

Messrs. Sturt Low and Co., Enfield, showed Pink Sensation, Gorgeous, Mephisto (perpetual *Malmaison*), and Philadelphia very finely. This firm also staged excellent *Cyclamens*.

Messrs. Allwood Brothers, Haywards Heath, again showed a general collection, giving prominence, however, to the new

perpetual border race of which Brilliant, Highland Lassic, and Rosalind are three of much promise. The garden, however, must be their test.

Mr. G. West, Datehet, had a small stand of his new pink Nora West. It is of a beautiful shade and free-flowering.

ORCHIDS.

Messrs. J. Cypher and Sons, Cheltenham, showed some particularly good *Cypripediums*, notably *C. Thompsoni* and *anreum virginalis*. *Cymbidium* *Gottianum* Albatross and *C. G. Butterfly*, with *Miltonia* St. Andre and *Cattleya* Octavie Doin, were also good. Among rarer kinds *Aerides* *Vandarum* (white) with nine racemes was worthy of remark.

Messrs. Low and Co., Jarvis Brook, Sussex, had a choice lot in which *Cattleya* *Percivaliana* Little Gem and *C. P. alba* were noted.

Messrs. Charlesworth and Co., Haywards Heath, had a group rich in *Odontoglossums* and *Odontiodas*, the former varied and beautiful, and including many finely-blotched varieties.

Messrs. J. and A. MacBean, Cooksbridge, had, among others, two fine novelties, *Odontoglossum* *amabile* (MacBean's variety) and *Cymbidium* *Alexanderi* aureum, both securing Awards of merit.

Messrs. Sander and Sons, St. Albans, showed the rich yellow *Odontoglossum* *Harvengtense*, *O. splendidum*, and *Odontioda* *Bradshawæ* among others.

Messrs. Armstrong and Brown, Tunbridge Wells, contributed *Cattleya* *Maggie Raphael* alba, *Lælia* *Gwenii* (yellow), together with a variety of richly-spotted *Odontoglossums* and some good *Odontiodas*.

FRUIT AND VEGETABLES.

Messrs. Sutton and Sons, Reading, had some six dozen heads of their Superb Early White Cauliflower, a self-protecting variety of much merit with white, finely-grained curd. Of model size, it is ideal at this season.

The Marquis of Ripon sent thirteen dishes of Apples, including Lane's, Bramley's, The Queen, and other well-known sorts.

A complete list of the certificated plants and medals awarded will be found in our advertisement columns.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Plants under trees (Englewick).—You will never be able to get Grass to grow, as the drip destroys it. Your best plan will be to plant one of the strong-growing Ivies or one of the *Vincas*. In the coming autumn you could introduce bulbs, which would look well coming through the groundwork of Ivy or Vinca.

The Candle plant (G. J. W., Balcombe).—The botanical name of the Candle plant, of which you send a specimen, is *Kleinia articulata*. It is a native of South Africa, and has long been grown in this country. It is of easy culture, and will grow well in the greenhouse, while in some districts it is often met with in cottage windows.

Pruning Roses (Amateur).—The wisest plan will be to wait until the early part of April at least before pruning your Rose-trees. If cut back now, and the present mild weather continues for a time, the back or lower buds will be forced into growth, and should cold or unfavourable weather then set in (which, under the circumstances, is extremely probable), the growths will sustain a check, and the bloom will suffer in consequence. If left alone, only the upper buds will start, and when these are cut away the lower ones will begin to push later on.

Forced bulbs (W. R.).—These are of very little future use. Do not stand them outside too soon after blooming. It is this unnatural treatment of exposing them to cold weather that has so much influence upon future usefulness. Dry them off gradually in a frame, and plant early in the autumn. Tulips and Daffodils will then give a fair show the next season, and improve by the following spring. Still, with the extreme cheapness of bulbs

now, we think it hardly worth while to trouble over those that have done duty as forced subjects, when the result at the best can only be inferior.

Growing Begonia Gloire de Lorraine (A Reader).—You have kept your plants too cold, hence their unsatisfactory condition. The culture of *Begonia* *Gloire de Lorraine* is not at all difficult, the principal thing being to obtain good cuttings in the spring, as the plant, being so free blooming, continues to bloom instead of growing, and it is useless to propagate from cuttings of the flowering shoots. After flowering, the old plants should be cut back, and young shoots will push from the base. These shoots, when from 1½ inches to 2 inches long, make the best of cuttings. Put them into well-drained pots filled with sandy soil, and stand in a close propagating case, where they will soon root and should be potted on as required. The young plants do best in a gentle heat early in the year. Later on they may be grown in a greenhouse or frame, but in the autumn heat is again necessary. A mixture of loam and leaf-mould, with a sprinkling of sand, will suit this *Begonia*, and when the pots are well filled with roots an occasional dose of liquid-manure is very beneficial.

FRUIT.

Nut-tree suckers (Filbert).—When any Nut or Filbert trees become thick with sucker growths at their base it is evident that no good culture has been given them. Your best course is to fork away several inches of the soil round the trees and cut out the suckers as close down to the roots as you can, doing it neatly and well. Then fork up the soil fully 4 feet wide round each tree, and give a top-dressing of manure. That should help next season to throw stronger growth into the heads, where it is needed. But you must also moderately thin the heads so that the wood and leafage get plenty of light and air. Whether your trees are common Nuts or are good Cohs or Filberts, good culture always pays.

MISCELLANEOUS.

Grafting-wax (Walter Chapman).—The following is a good recipe for making grafting-wax: Melt in a basin 1 lb. of tallow, 2 lb. of bees' wax, and 4 lb. of resin, stir well together, and keep in a cool place in the dish it was melted in. Another very good recipe is to take common red or black sealing-wax one part, mutton fat one part, white wax one part, and honey one-eighth part. First melt the white wax and fat, then add the sealing-wax gradually in small pieces, the mixture being constantly stirred, and lastly add the honey just prior to lifting the mixture off the fire. It can be put into tins or moulds to be kept till wanted. Then as fast as the grafts are inserted and tied the union should be coated over with the wax in a warm, semi-liquid state.

SHORT REPLIES.

A. L. Wheeler.—Impossible to say what you can do to prevent the damage. Kindly send us some of the flowers and leaves, and then we may possibly be able to help you.—*W. Brown.*—Your best plan will be to procure a copy of "Vines and Vine Culture," A. F. Barton, from Mrs. Barron, 13, Sutton Court-road, Chiswick, London, W., price 5s. 6d., post free.—*J. M. D.*—We have not at hand an analysis of spent Hops, but their actual manurial value in the natural condition is very small. You will find Wakeley's Hop manure very good, and reasonable in price.

D. W. H.—The shape of your flowers is correct. They are globular and not slender.

James Laver.—Ginseng is the root of one or more species of *Panax*. That known as Ginseng is *Panax quinquefolium* (syn. *Aralia quinquefolia*).

NAMES OF PLANTS AND FRUITS.

Names of plants.—*H. F. W.*—Looks like *Chionodoxa sardensis*, but from such a poor specimen it is very hard to say.—*A. B. G. L.*—*Rhododendron præcox*.

Name of fruit.—*J. Kelly.*—Apple not recognised. Please send when in season.

NOTES OF THE WEEK.

Prunus Davidiana.—The pink and white forms of *Prunus Davidiana*, which made quite a show in January, are over now. The white variety is the better in some ways, flowers larger and more numerous than on the pink variety, but both are invaluable.—BROADWAY.

Erica ciliaris alba is a lovely addition to the list of dwarf hardy Heaths. It is a soft French white in tint, and its elongated bells are the largest of all the family with the single exception of the so-called Connemara Heath. I have grown this white *E. ciliaris* for three years, but so far have failed to trace its origin. As I like to know the history of a plant I shall be glad if any of your readers can enlighten me.—J. STORMONTH, *The Nurseries, Kirkbride, Carlisle.*

Sweet Pea Margaret Atlee.—I tried this Pea last year, and while I think that we have already too many in which pink is the predominating colour, yet the particular shade in Margaret Atlee was, to me, new. The blooms, produced on long stems, number always three, often four, and are exceptionally large. An objectionable feature—to me, at all events—is the proportion of duplex blooms, of which I am no admirer, thrown by this otherwise first-class Sweet Pea.—W. MCG., *Balmac.*

The Spurge Laurel (*Daphne Laureola*) is now (January 20) in bloom, and although its flowers are not attractive, the delicious perfume from a group of plants fills the air towards evening. The green flowers are abundantly produced on short stalks from the axils of the rosette of leaves which clothe the extremities of the branches. So thickly are the flowers produced that quite a cushion is formed around the stem. As a dwarf evergreen it is very welcome, and although it is planted here in the poorest of soil and in a rather exposed position, it is doing well.—E. M., *Sussex.*

Ribes sanguineum.—Judging by present appearances the Flowering Currants will anticipate their usual date of blooming. On January 26th I noticed a plant just on the point of flowering, the colour being quite distinct. A curious point in connection with this particular plant is that it is growing in a most exposed situation in which it gets the full force of the east winds which prevail here at this time. In addition, the soil in which it is planted is by no means first-rate, but in spite of these

drawbacks the plant is quite healthy. In warm positions the plants of Flowering Currants are well forward, but that in the exposed place will be the first in bloom.—W. MCG., *Balmac.*

Grabbing coppers and wasting millions.—People may well be surprised that a penny is charged to go into Kew Gardens, which have been open free to the public for seventy years. One might perhaps as well expect a penny to be charged for admission to Hyde Park. This is one of the blessings of government by lawyers away from their briefs, which we have now enjoyed for some years. The abortive and harmful Land Act between public and private expenditure has cost the country about nine millions sterling, and is only one of the enormous expenses we have been put to by the Government, impoverishing the country by hasty and unwise legislation. Look at the many millions robbed from the arable fields of Great Britain and Ireland by the pretended Free Trade.—W.

Melville's Snowdrop.—*Galanthus nivalis* Melville has been finely in flower for some time with me. This variety, which has not increased very quickly, is a seedling of *G. nivalis*. It is probably the finest of all the pure seedlings of *G. nivalis*, apart from its South European form, *G. u. Imperati*, and was awarded a first-class certificate by the Royal Horticultural Society in 1879. As its raiser, Mr. Melville, of Dunrobin Castle, Sutherland, said, "It is larger in all its parts than *nivalis*, the bulbs being sometimes nearly double the size." It has, in addition, longer flower-stalks, the blooms of greater substance and more beautiful in form than those of the type. *Galanthus Melvillei*, sometimes called *G. Melvillei* major, is rare in gardens, and still rarer in the trade.—S. ARNOTT.

Begonia fuchsoides.—I was much interested in J. Comber's note on this plant (p. 54), together with the editorial comment. The variety which I have been growing for many years is, no doubt, *Begonia fuchsoides* *miniata*. Be that as it may, the variety deserves all the praise given to it in my previous note, and is, I think, to be preferred—judging from the description given—to the true *B. fuchsoides*. I have a recollection of what was probably the latter *Begonia* dating from my apprentice days, when a stronger and much more robust plant was grown in balloon shape for exhibition. I had quite forgotten this until J. Comber's note re-

called the fact to my memory. It is pleasing to see that there is yet some interest taken in the older race of greenhouse plants.—W. MCGUFFOG.

Iris reticulata in the north.—A little clump of this on the sunny slopes of the rock garden was in full flower here on January 30th. This is, I think, much earlier than I can recollect for a long time, my records generally giving it as flowering well into February—often about the end of the month. *I. histrioides* is a little earlier. *I. histrio* is not very satisfactory with me in the open. *I. reticulata*, *I. r. Krelagei*, and *I. r. major* are all so satisfactory that those who do not grow *I. histrio* need not trouble about it, unless they have an alpine house or frame under which to grow it. On January 29th I was in a garden which is usually a fortnight at least earlier than mine, and there *I. reticulata* was not in bloom.—S. ARNOTT, *Sunnymead, Maxwelltown, Dumfries.*

Prunus tomentosa.—This is one of the first of the *Prunus* family to flower, being usually at its best early in March. This year, however, it was nicely in flower by February 5th. A native of north and west China, it was introduced to this country about 1875, but was comparatively unknown until ten years ago. The flowers, white tinged with rose, are readily injured or destroyed by stormy weather, otherwise they are borne with such freedom from buds all along the previous year's shoots that a bush in full bloom is very effective, the branches almost hidden by flowers. It thrives in any good, well-drained soil, but should have a position sheltered from north and east. Exposure to sun is, however, necessary. Do not plant on cold, wet soil, for if that is done, growth will probably be unsatisfactory and flowering will suffer.—D.

Bacterised peat.—This is rather a complicated business, and remains at present in the hands of the scientist. If it is made too expensive for common use by the practical farmer or gardener it may remain in the bog or fen. I had some acquaintance with the bogs in Ireland many years ago, and since then I have lived twenty years close to what was formerly Whittlesea Mere, which, after being drained and brought under cultivation, is now generally known as the Golden Plain of England, by reason of its wide stretch of golden corn. There is no better corn and root land to be found anywhere, and it has been undergoing for many years a course of improvement.

Beneath the bog, which varies in depth, there lies a stratum of boulder clay, commonly termed Oxford clay, and the practical farmer has found that by mixing the clay with the bog he has immensely improved the whole for farm, fruit, and garden crops.—E. H.

The Swan River Daisy (*Brachycome ibridifolia*).—Among some of the less known half-hardy annuals we must place this, popularly known as the Swan River Daisy. It is one of the many neglected plants, and I should like to say a word or two about it. Grown in the same way as other half-hardy annuals and planted out in the beds or in the mixed border in the last week in May it looks a picture with its white, blue, and rose flowers, which somewhat resemble those of *Cinerarias*. Its flowers, though small, are very freely produced, and the plant blooms from the end of June onwards. It may also be sown out of doors in a well-prepared border, and in some localities better results are obtained in this way. In cold districts it is better to sow in February in heat and harden off in the usual way. Its height is 6 inches to 9 inches, and it should be much more often grown than it is.—E. T. ELLIS, *Westwood, Ecclesall, Sheffield*.

[The best little flower we owe so far to the vast land of Australia, and happy in our clime, too, as any native plant.—Ed.]

Corylopsis pauciflora.—There are several species, all early spring flowering, and all of Asiatic origin. From the specific name one might imagine that the species under notice had little flower beauty to commend it, but it is really a free-flowering shrub. A native of Japan, it has been in cultivation twenty years or more, but is not widely grown, owing, no doubt, to its early growth and its liability to injury from late spring frosts. Mature plants are 3 feet to 4 feet high, with numerous slender branches, from which the catkins of fragrant, pale yellow blossoms appear in advance of the leaves, sometimes as early as February, though usually in March or early April. In addition to the flowers, the young leaves are also effective, the central portion being pale green and the margin bright reddish-brown. Where it cannot be grown out-of-doors it may well be given a place in a cold greenhouse. It should be given well-drained, light, loamy soil, to which a little peat has been added.—D.

Carnation Bedford Belle.—Among modern Carnations, this fine salmon-pink sort, raised at Bedford by Messrs. Laxton Bros., ranks high. Only describable in general terms in the colour tone indicated above, and from which, so far as catalogue descriptions go, it may not differ from a dozen others, the variety unmistakably possesses a shade of its own—a glowing tone, as also a certain depth or intensity, which catches the eye at once—in fine, a “faking” colour. To such good attributes must be added fragrance—a chief recommendation after colour, seeing sweet-scented flowers are valued most in decoration—and freedom of flowering. It is not one of the biggest Carnations ever raised, a fact which accounts for its consistent, well-nigh perpetual, blooming. It is, however, large enough for all purposes, its bushy habit suggestive of the crop it is capable of producing. Bedford Belle has already secured an Award of merit.—E. H. JENKINS.

Outdoor Chrysanthemums.—“M. L. W.” (January 22nd, p. 42) will find the following varieties very satisfactory:—Brighton, J. Bannister, Leslie, and Perfection (light and deep yellows); Normandie, Provence, Nellie Hensley, Lillie, Goacher's Pink, and Dolly Reeves (light and deep pinks); Crimson Diana, Crimson Grunerwald, and

Beacon (crimson); White Beauty, Roi des Blancs, Mytchet White, Hermione, Emily, and Boule de Neige excellent whites. The above-named varieties flower from the second week in August to the middle of October, but are at their best in September. Of singles, Mary is very similar to Mary Richardson in colour and form of flower. The colour is salmon suffused with red; season of flowering, end of August and throughout September. It grows only 2 feet high. Surrey, Robin, Kate Carter, Dora, and Canada are also early-flowering singles, reddish-salmon in colour. None of them need staking in the open border. Lady Furrness is of the same colour as Mary Richardson, but much later. Rosalinde (soft pink), Nellie Riding (reddish-salmon), Peter Pan (fawn), Mrs. H. Hogben (orange-bronze), Grace Darling (white), Elsa (white), Ceddie White (chestnut on gold ground), and Catherine Hope (orange terra-cotta) are all good companions to the variety Ladysmith.—BOURNE VALE.

The Cornelian Cherry (*Cornus Mas*).—As the Witch Hazels decline in beauty the flowers of the Cornelian Cherry begin to expand, and a bush in full flower is as effective, if not quite as interesting, as a Witch Hazel, for the leafless branches are thickly studded with small clusters of yellow blossoms, which are often at their best between mid-February and early March. Although usually seen in bush form it sometimes grows into a small tree over 20 feet high. It is a native of Southern Europe and is naturalised in woods and plantations in some parts of the British Isles. The yellow flowers are very small, but what they lack in size is compensated for by their number. The common name refers to the yellow and red oval fruits, somewhat resembling a Cherry, which ripen in June. The *Cornus C. officinalis* is very similar in all respects to *C. Mas*, and is probably but an Asiatic form of the European plant. Both species may be best increased by seeds, although layers and cuttings may also be used.—D.

Camellia reticulata.—So far as individual flowers are concerned this is the most beautiful of the cultivated Camellias, but, unfortunately, it is not so hardy as *C. japonica*, and can only be grown out-of-doors in the mildest parts of the country, and even then it should be planted against a wall or in a very sheltered corner. It is a native of China and was originally introduced about 1820. The semi-double flowers are each upwards of 6 inches across, the large, irregular, rose or light red petals enclosing a central mass of golden stamens, each individual blossom bearing a striking resemblance to the flower of a semi-double *Pæony*. In districts where it cannot be grown outside it may well be given a place in a cool greenhouse or conservatory, where, during February, it may be expected to bloom freely. For indoor work the best results are obtained by planting it in a well-drained and well-prepared border of light, loamy soil containing a little peat. Propagation is effected by grafting it upon stocks of *C. japonica*.—D.

Iris reticulata and disease.—We are indebted to “Kirk” for his notes on this. While it is certainly “reasonable to infer that healthy bulbs planted in a favourable situation and with congenial soil would remain healthy,” it is possible that they would not. It must be admitted, also, that “if the spores are in the soil a good position and exposure would assist in maintaining such bulbs in vigorous health and less liable to be affected by disease.” All this granted, neither of these factors would give immunity. The great trouble is that the disease will appear

even under ideal conditions and cause serious losses. Sir Michael Foster told us—and his statements have been supported by the experience of many others—that “in any garden to which the fungus has gained access, bulbs left in the ground soon perish; what one year is a beautiful clump of bloom may next year be represented by one or two flowers only, or not even by that. . . . By this method” (*i.e.*, lifting and removing the coats which show signs of fungus) “I find that I largely diminish the disease, though I have not as yet wholly stamped it out.” He then refers to no variety being disease-proof, and says: “If I fancy one kind is disease-proof because it stands for several years, I am undeceived at last.” In my own garden I have had a clump for ten years and which has survived where others in similar positions have perished. It cannot be said that apparently healthy bulbs of *I. reticulata* will if planted under favourable conditions remain free from the disease. It may not be present to appearance, yet a few spores may be lurking somewhere, only awaiting certain conditions to attack the plants. “Kirk” is right in advocating giving *I. reticulata* every chance, but it is only fair to warn readers that these precautions will not avail to prevent the disease making its appearance when and where it will.—S. A.

Transplanting Christmas Roses.—In reply to Mr. Jenkins' criticism of my notes at page 62, I have had quite satisfactory results by dividing and replanting Christmas Roses at the end of January in the West Midlands, and I anticipate equal success by January planting in the South Midlands. Had Mr. Jenkins to deal with the clumps in question he would have found it impossible to divide them successfully without first washing out the soil. Moreover, unhealthy clumps of this plant always contain a lot of decayed roots, which should be carefully removed before replanting. This it is impossible to do effectually without first washing out the soil, and in dealing with clumps of this description I contend that it is the best and correct method. I admit that strong, healthy clumps can well be divided without resorting to the washing out process. A “single jet syringe” will be found expeditious (and not frivolous) in dislodging the clayey soil from the centres of the clumps, and although “tepid water” is by no means essential for what we all know to be perfectly hardy plants, it will be found quicker and more comfortable to work with than “very cold water,” and in no way detrimental to the plants.—F. W. GALLOP.

—Mr. Jenkins has done timely service in prescribing considerate treatment of these most charming plants, for it is seldom indeed that one sees them as they might and should be. But there is one omission in his advice—he does not take variety of climate into account. I do not know where his garden is situated, but it is evidently not on the west coast, where the atmosphere is charged with far more humidity than it is over midland districts. If we in the west were to disturb *Hellebores* in September we should run the risk of their being seriously injured by winter wet. Moreover, the finest of all, *H. niger altifolius*, begins flowering in October, and the display would be spoilt if the plants were broken up in September. We transplant in March into deeply-trenched ground, and the plants grow through the summer without the slightest check. But I can easily understand that in districts where the sun is stronger and the air drier newly-moved plants would receive a serious check from summer drought.—HERBERT MAXWELL, *Mourveth*.

FRUIT.

PEAR OLIVIER DES SERRES.

THIS Pear comes in during January, and in some seasons will last throughout February. It is, as may be seen by the illustration, of distinct form—almost Apple-shaped—and of a russetty colour when well grown. The flavour is excellent and as good as that of any Pear then in season. It is of moderate size. It was raised by M. Boisbunel, of Rouen, about 1859, and first fruited in 1864. It succeeds either on the Quince or the Pear.

PEACH TREES IN SPRING.

I HAVE just seen a span-roofed house, nearly 100 feet long, filled with healthy trees, but badly mismanaged. The training has been so faulty that there is four times the number of young shoots that there is room for. Instead of judicious disbudding having been the rule last year

Avoid having several of extra strength by rubbing off those young shoots that promise to be such before they are 4 inches long, and so secure a tree with the main branches of medium and even strength, and smaller ones that are very short-jointed and will mature well. A branch about 18 inches long should have, when finally disbudded, about three young shoots left on it, one at its base, one near the centre, and another near the point. One 12 inches long should be disbudded till two young shoots are left on.

G. G. B.

CORDON PEARS.

THE note at p. 2 on cordon Pears was very interesting, and "E. B. S." might with advantage have included other fruits grown as cordons, notably Plums. I have seen many failures with these, and should hesitate to advise anyone to grow the Plum as a cordon. I have had failures with most varieties and rarely seen what one could term good crops. I think

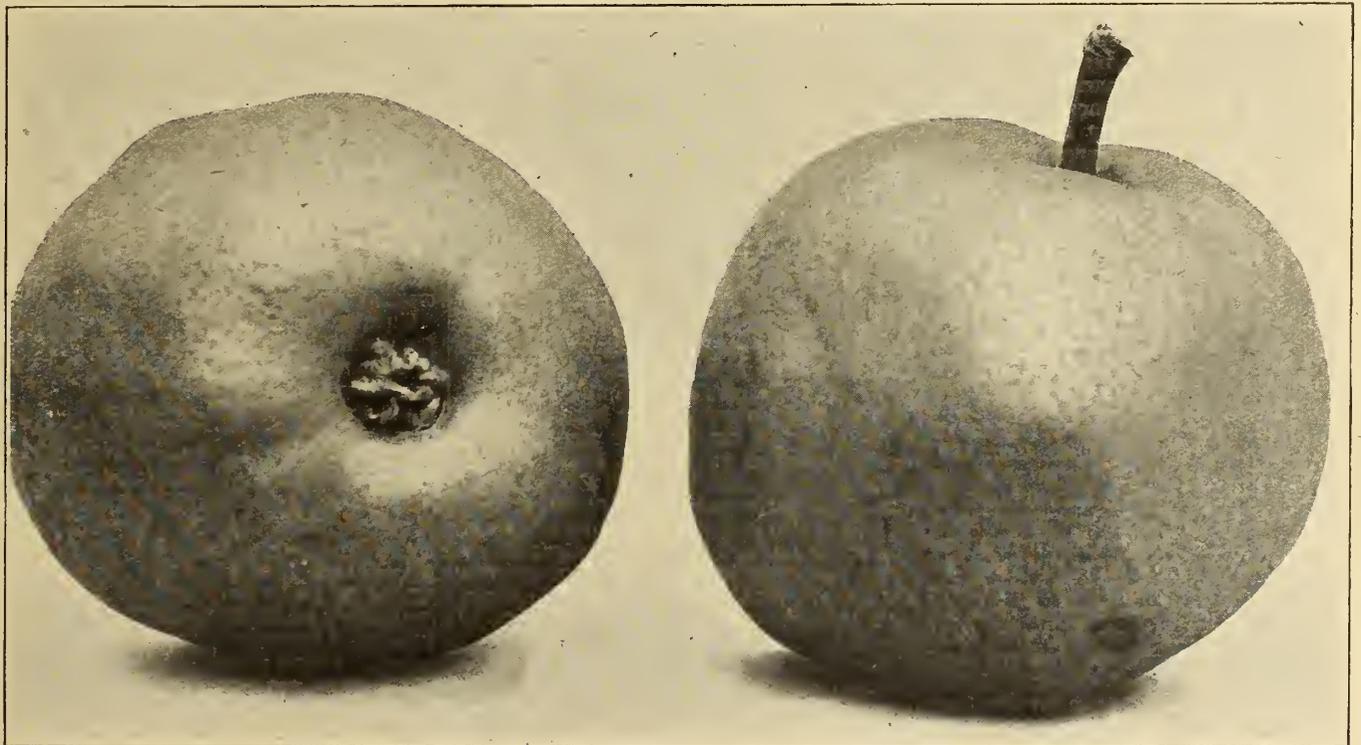

In my opinion it is, when at its best, little inferior to Doyenné du Comice. With me Doyenné du Comice is none too free, though given good soil and pinched at the right time. My cordons of this variety are not very old. Though the trees occupy the best place on a wall facing south-east, where other varieties succeed, I find bush trees in the open are far superior as regards cropping.

C. R.

THE NEWTOWN PIPPIN.

How many Apple-growers are acquainted with the romantic history of the Newtown Pippin? This variety gave rise to the establishment of our export trade to Great Britain, a business that has been developed within the last hundred years by such strides that we now mention it in terms of millions of barrels annually.

About two centuries ago a seedling Apple-tree sprang up on the edge of a swamp in the neighbourhood of the village of Newtown, Long Island. From what variety of Apple that seed came we cannot

Pear Olivier des Serres. From a photograph of fruits grown at Gravetye Manor, East Grinstead, Sussex.

nearly all the young shoots were allowed to grow.

NEWLY-PLANTED TREES.—When grown under glass the structure should be kept cool, then the growth of shoots and roots will be steady and of a healthy nature. The trees will have been cut back so that a good foundation of new branches will result. These branches will be from seven to fourteen in number—nine being a fair average. They should be so trained that the whole of the wall or trellis space is filled with short-jointed young shoots tied in at 4 inches to 6 inches apart. All the shoots growing out at right angles from the wall or trellis should be removed.

ESTABLISHED TREES.—When well managed, trees begin to fruit the second year after planting. I know of one case, however, where the trees did not bear till the end of seven years, notwithstanding root-pruning had been done and careful attention given by an expert grower. This is, of course, exceptional. When the trees did bear, the fruits were very fine. Young shoots of medium strength are the best.

"E. B. S." has touched upon the weak spot, viz., the summer pinching or pruning being done too early. I quite agree that such work results in a mass of worthless growth which is cut away time after time, the result being few fruits and often none at all. The advice given to prune when the new wood has hardened a little is well worth attention. A Pear that has never failed with me as a cordon and one that makes little gross wood—indeed, its free-fruited every year or nearly so prevents this—is the well-known Louise Bonne of Jersey, I think one of the best cordon Pears we have when crop and quality are considered. My worst cordon as regards bearing is Pitmaston Duchess, whose only merit is its size. Marguerite Marrilat, a very large early fruit, a very strong grower, but totally different from Duchess in having short jointed wood, makes a very fair cordon treated as advised by "E. B. S.," that is, not stopped too early. I also like Beurré Superfin as a cordon. It is not so reliable as Louise Bonne, but usually gives a fair crop every other year.

tell. This seedling was allowed to grow, unmolested, ignored, as such trees are, until one day a stranger passing by saw and tasted some of the fruit from this tree. He found the flavour better than anything he had ever tasted.

In 1758 a box of Newtown Pippins was sent to Benjamin Franklin, our representative in England. He gave some to his friend, the English botanist, Peter Collinson, who then brought scions into England. The trees had but meagre success in English orchards, but the fruits were popular in the markets of London. Though to Franklin must be given the honour of introducing American Apples to the English people, the export trade was really inaugurated through the efforts of Andrew Stevenson, of Albemarle County, Virginia, who was minister to the Court of St. James in the first year of Queen Victoria's reign. While in England he had Pippins sent from home for his own use, and he presented several barrels to the Queen, who was so much pleased with the excellent quality and flavour of the

Apples that she rewarded Stevenson's courtesy by having the small import duty on Apples removed. Robert Pell, of Ulster County, New York, owned in 1845 an orchard containing a large number of Newtown Pippin trees. They yielded that year a crop which sold in the London market for as high as twenty-one dollars a barrel!—SYDNEY F. BROWN in *American Country Gentleman*.

GRAPES WITHOUT HEAT.

Will you please let us have an article as soon as possible upon how to treat Vines without heat? So much coal and coke are now needed for ammunition work that we feel they ought not to be used where they can be done without.—L. A. BOSTON.

—I have a viney which I do not want to heat this season if I can possibly avoid doing so, on account of the high prices of coal and coke and not requiring the Grapes. I do not want to injure the Vines (Black Alicante) for future years, as above proposed measures are only temporary. What is the best procedure in your opinion? Shall I leave the Grapes on the Vine or cut them off, and what pruning is desirable? The Grapes without fire would become mildewed in the house where they are growing, as I know from experience.—J. N. P.

[That this can be accomplished has on more than one occasion been clearly proved. The results, as a matter of course, largely depend on the weather, for the finer and warmer the summer and autumn are, the more satisfactory the outcome. The greatest measure of success has been achieved with varieties which require a shorter period of growth and are so constituted that they do not require nearly the amount of heat to assist in the production and perfecting of the crop, as is the case with those for which artificial warmth is considered a necessity. Under the first heading should be placed Black Hambro, Foster's Seedling, Buckland Sweetwater, Royal Muscadine, Black Alicante, Gros Maroc, and Appley Towers. Under the second come the different varieties of Muscats, both black and white, Gros Colman, Lady Downe's, and other late-keeping varieties which require a long season in which to ripen. The whole of the latter may be left to start naturally in the end of March or early in April, and it may be possible, if climatic conditions are favourable, that the various stages, such as flowering, setting, and stoning, can, with the aid of solar heat, be reached and successfully passed. But the crucial test comes when the berries take on the final swelling and begin to colour. Sun-heat may, if the autumn is fine and dry, suffice for a time, but fire-heat is absolutely necessary to obtain a proper and perfect maturation of the fruit afterwards. With regard to the varieties first enumerated these, owing to their needing much less time in which to bring their crops to perfection, can, by a judicious use of sun-heat, be grown without the aid of artificial warmth, provided, of course, the season is favourable, but the flavour in respect to the last three-named sorts would not be so good, neither would their keeping properties be of the same high order as when the finish is attained with the aid of fire-heat.

As in the case of Muscats, and late-keeping varieties in general, starting of the Vines should be deferred as long as is permissible, and then the viney or vineries must be closed. The subsequent treatment would then be on somewhat similar lines to that accorded Vines grown in the usual way, with the exception that ventilation, syringing, and damping would have to have very careful attention until the month of May is passed, otherwise an attack of mildew might result, especially if the wind is in a cold quarter. On dull and cool days it would be best to omit the damping down and to keep the ventilators

closed. Until the stoning period is safely passed the top ventilators only should be used to admit air, as ventilation from the front is often the cause of an attack of mildew in a heated viney, let alone one in which Grapes are being grown without artificial heat. In sunny weather air should be shut off in time to secure a temperature of 80 degs. to 85 degs., which will assist in maintaining a comfortable atmosphere through the night. A dry, warm condition of the air is, of course, essential when the flowering stage is reached; also while the Grapes are setting, and if the weather is dull at the time, artificial aid in the setting would render it the more certain. Once warm summer weather sets in, the chief difficulties will have been surmounted, and from then and until the berries have finished colouring and are ripe the treatment is precisely the same as when the Vines are being grown under normal conditions. In many gardens it is the rule to let the fires go out when hot weather prevails, but it is false economy so far as Muscats and late varieties are concerned, as a heavier expenditure for fuel is incurred later in the season in order to get the Grapes thoroughly ripened. In the old Chiswick days the finest bunches of Madresfield Court were always obtained from a Vine which was grown in a cold house facing due south.]

APPLE TREES FOR PICTORIAL EFFECT.

MR. JAMES HUDSON concludes an interesting summary, "Concerning Apples," at page 73, with the remark, "I have for a long time thought that we might plant standard Apple-trees in our shrubberies for pictorial effect." It is surprising it is not more frequently done. Too often, however, the shrubbery is but a meaningless jungle of evergreens so hemmed in on all sides as to preclude the possibility of development of any plant, hence loss of form and all that is good. Crowding at the start is responsible for much, neglect of subsequent thinning and timely pruning for much more, hence the deplorable results too often seen. In these circumstances the shrubbery has little of beauty, and reformation should be the order of the day.

Fruit—home-grown fruit—everybody values, and by adopting Mr. Hudson's suggestion the usually unkempt shrubbery might be made productive of both the beautiful and the useful. A lady whom I had the privilege of knowing for many years at Hampton Hill, and who gardened for the love of it, went even further than Mr. Hudson's suggestion indicates, and, having turned the shrubbery borders to good account by planting the best cooking and dessert Apples there, presently encroached upon the lawn in positions where, as she used laughingly to tell her gardener, she could "see the pictures from the windows and have a few more fruits to give away in the autumn into the bargain." When I first saw the garden in question, twenty-five or so years ago, the Apple-tree on lawn and in the border was new to me, though its purport was obvious at a glance. There was no crowding of the trees, no attempt to get as many on the ground as possible, every tree held its own, as it were, and light and air reaching the trees on all sides very heavy crops resulted from those usually isolated examples. Much might be said in favour of an extension of the idea if it were necessary, though its merits will be obvious to all. What is necessary to-day, now that economies of all kinds are in the air, is that those having gardens in process of formation should discourage the lumber of the shrubbery and like places—Privet,

Portugal Laurel, etc., soil robbers in very truth—and in their stead plant discreetly of the finer fruits, more particularly such as the Apple, and so combine the useful and the beautiful. E. H. JENKINS.

OVER-RATED PEARS.

DESPITE recommendations oft repeated as to the best Pears, those of second rate quality, or even lower still, continue to be planted largely, and I suppose will be all the time they are catalogued and stocked in nurseries. This may be attributed to several causes, the two principal being their prolific cropping or their size. A notable case in point of the first cause is Marie Louise d'Uccle, which the late Mr. Blackmore rightly described as "not to be compared with the old Marie Louise, but tenfold the cropper." There are very few seasons when given spring protection this variety does not crop heavily, and, if thinned, the fruit is large and handsome. It is said to be satisfactory on most soils, but I cannot say this has been my experience. On the contrary, the fruit developed mealiness with the ripening stage and was very short-lived. Another very heavy cropping Pear that was formerly very popular, and is still planted, is Passe Colmar. It is said to occasionally prove melting and buttery, but in the majority of districts, although very juicy, is decidedly insipid. Another heavy cropping Pear as a cordon, popular, but decidedly second-rate, is Beurré Bachelier. The list could be largely increased of those which seem to be chosen, as above stated, because they are heavy and consistent croppers.

Turning to Pears that are chosen mainly for their size, the first name to strike one is undoubtedly Pitmaston Duchess, which has very little except its size to recommend it. There is considerable difference of opinion respecting the large, highly-perfumed Pears like William's in the early and Conseiller de la Cœur and Van Mons le Clerc in the later, those not objecting to the high flavour liking them very much, while others equally dislike them. The flavour in these is very pronounced. Where it is less so, and of a different character, as in Gansel's Bergamot and Vineuse, I have never heard any objection raised. I have never found the best Pears very heavy croppers, with the exception, perhaps, of Beurré Hardy—that is, if they were doing well, but a few are hardly satisfactory as cordons unless double grafted, three that are called to mind being Gansel's Bergamot, above mentioned, Josephine de Malines, and Marguerite Marillat. Although strong objections may be raised to planting too many varieties rather than a few of the best, exception might be made in the case of the latest. Varying as these do in different soils and situations, it is worth finding out the most suitable for the locality.

Hardwick.

E. B. S.

NOTES AND REPLIES.

Injury to Apple branch.—I should be much obliged if you would kindly say what insect has caused the damage to the trunk of Apple-tree herewith. Is there any way of protecting against such ravages?—A. A. LUCAS.

[The piece of Apple growth you send has been bored by the caterpillar of the Wood leopard moth (*Zeuzera aesculi*), a by no means uncommon insect. The presence of one of these caterpillars in a branch may be detected by finding small dust-like particles sticking to the tree where a little moisture is oozing from the bark. On closer examination a hole will be found from which these particles (which are composed of the small pieces of the wood gnawed off by the caterpillar) are exuding. The easiest way to destroy it is to pass a

sharp-pointed wire as far as possible into the hole, which will usually be found to proceed upwards, so as to stab the caterpillar. It can usually be seen by the appearance of the wire whether the insect has been reached or not. If by any turn in the channel it has not, the entrance to the tunnel should be slightly enlarged and some cotton wool or tow soaked in tar or paraffin pushed into it as far as possible so as to stifle the insect. The mouth of the hole should be closed tightly with a plug of clay so as to keep the smell in. If it is possible to cut off the branch without injury to the tree you can then, by splitting it open and killing the insect, make sure that it is destroyed.]

The Alexandra, autumn-fruiting Raspberry.—In a recent issue "E. K." gives his experience of Raspberry November Abundance, and advises the planting of strong canes every third year. I grow the Alexandra, which gives an abundance of delicious fruit from early in August till frost cuts it off in November. I find it

cropper, also produced smaller fruits, and eventually it was removed. Some people, I imagine, over-prune Bismarck, and for years I thinned only where this was necessary. So treated the trees were a picture when in fruit, particularly when, as September waned, the branches were traced to their tips with brilliantly-coloured fruits. The variety in question was valued for other good qualities apart from consistent cropping; more particularly the fineness of its pulp when cooked, smallness of core—hence little waste—and long keeping. In all probability this latter was, in great measure, due to well-matured fruits—I never gathered them before October 19th—and by storage in a cellar which was constantly as well as uniformly cool. Too early gathering and too dry a store will promptly ruin the finest Apples. —E. H. JENKINS.

Manuring fruit-trees.—The most useful roots are those within a foot of the surface, and to encourage their action they must be fed on the surface. The present

sists in cutting back all spur wood to one bud, or at the most two buds, at the base. The rods, whether trained vertically or horizontally, should have their fastenings examined and made good, if necessary, as nothing is more annoying than to have these give way later when the Vines are in fruit. Stout tarred twine should be used for this. When the border is turfed over, almost, if not quite, close up to the stems little or nothing can be done in the way of manuring, but if it is used for the growing of annuals or is lightly cropped, a dressing of Vine manure forked in now at the rate of 1 lb. per square yard will prove beneficial.

PLANTS AND FLOWERS.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

IRIS HISTRIOIDES MAJOR.

THIS is one of the best of the early spring-flowering Irises, and is of easy culture.

The flowers are larger than those of any of the group, of a rich blue colour, with faint white veins and yellow ridge on the blade of the falls. It is also sweet-scented. Slugs are its greatest enemies, and the plants should be protected from these by placing a layer of ashes around them. The illustration shows it growing in the rock garden associated with *Galanthus Elwesi robustus*, but it is not easy to convey an idea of its beauty in this way.

F. W. G.

*Lilford Hall Gardens,
Oundle, Northants.*

NOTES AND REPLIES.

The Prostrate Rosemary.—This rock plant thoroughly deserves the appreciation given it by "E. M." in the issue for January 29. He is fortunate in finding it hardy, but it is not sufficiently so to stand the winter everywhere, and is not specially hardy with many, even in gardens in comparatively mild districts. It is always safer to keep a spare plant or two under glass in winter so as to be in a position to replace any which may be lost in the open. It certainly stands some winters here, but in others it has been lost. I have had considerable correspondence with friends concerning it, and except in the south of England and in Ireland they generally agree that the Prostrate Rosemary is not absolutely hardy.

—S. ARNOTT, *Sunnymead, Maxwelltown, Dumfries.*

Treatment of low wall.—I should like your advice respecting a low wall, facing south, in which a number of bricks are missed out at regular intervals. It seems to me that if the spaces were filled with soil a nice little wall garden could be arranged. I should be glad to hear what you would advise me to grow and how to plant them.—WILL MELLAND.

[There is, perhaps, hope of success in respect of the wall, though this may be subject to qualification. For example, if only brick spaces are missed and the roots of the plants cannot reach a soil bank or soil cavities elsewhere in the wall most plants would be starved. Then, again, is the wall generally rendered vertically and with good mortar? A vertical wall is bad for plants; with good mortar and clean-struck joints it is worse. If you will send us a few more definite particulars we will do our best to help you.]

Wahlenbergia Pumilio.—Forming attractive and neat tufts, this does well in the rock garden, more particularly when given a sunny and warm position. It is equally valuable in retaining walls. *W. Pumilio* can be raised from seed, but unless sown just when ripe it

Iris histrioides major and Galanthus Elwesi robustus in the rock garden at Lilford Hall, Oundle, Northants.

gives the heaviest crop, and finest fruit, if lifted annually and transplanted to fresh ground that has been given a good preparation. After cutting the old canes down to the ground the roots are divided, if too large, as I find about six new canes from each stool quite sufficient. When they have made, say, 9 inches of growth, six of the strongest shoots are selected, the weaker ones cut away, as too many canes give too much shade. The rows are 5 feet apart and 2 feet 6 inches from plant to plant. The bountiful supply of fruit obtained over a long period well repays for the trouble of transplanting annually. A few stakes and a strained wire, to give each cane one tie, is all the support they require. —WM. ALLAN, *Gunton Park Gardens.*

Apple Bismarck.—I notice that Mr. Hudson (February 5th, p. 72) has a good word to say for the consistent cropping of this fine Apple. I grew it for many years in my old home, and every tree, with one exception, fruited every year. That particular tree, while a less consistent

is a good time to apply a surface-dressing of manure, which may include ½ lb. or so to the square yard of basic slag. This may be used separately or mixed with any other suitable dressing and worked in with hoe and rake, or, if the trees are on Grass, brushed in with a stubby Birch-broom. Cesspools may be emptied—diluted if necessary—on the roots of fruit-trees in the orchard. Holes can be made with a crowbar at intervals of a foot or so, by which it can pass to the roots. A top-dressing of manure may be given to Gooseberries and other bush fruit and Raspberries. There is a double advantage in this top-dressing, as, besides feeding the roots, it helps to retain the moisture that would otherwise escape.—E. H.

Outdoor Vines.—Although the return from these is, taking the generality of seasons, but poor, what is lacking in the way of fruit is compensated for by the ornamental character of the foliage and the beautiful tints assumed by the leaves in autumn. To avoid bleeding, pruning should no longer be delayed. This con-

sometimes takes a long time to germinate. The flowers, of a good shade of pale-blue, and large in comparison to the size of the plant, are very freely produced.—KIRK.

ROSES.

ROSES FOR GROWING ON S.E. WALL. (REPLY TO AMATEUR.)

The list of Roses given by you might be divided into three groups as follows:—

(1) Those of upright, semi-climbing habit—Mrs. John Laing, Dr. O'Donel Browne, and Louis van Houtte.

(2) Those of fairly tall but more freely-branching habit—Mme. Jean Dupuy, Gustave Grunerwald, Marie van Houtte, Mme. Lambert, Alfred Colomb, and Mme. Abel Chatenay.

(3) Those of more spreading habit—Gen. McArthur, Lyons Rose, Grace Darling, and Mme. Ravary.

The nine varieties that we would select for growing upon a wall having a S.E. aspect would be Louis van Houtte, Mme. Jean Dupuy, Gustave Grunerwald, Marie van Houtte, Mme. Lambert, Mme. Abel Chatenay, Gen. McArthur, Lyons Rose, and Grace Darling. The majority of these being, strictly speaking, dwarf Roses, it would take three or four seasons before they would attain the height of 5 feet, especially as you describe the soil as being only medium, but once the plants had become established you would obtain far more flowers from them than if you used more vigorous varieties.

A wall with such a favourable aspect deserves to be clothed with a selection of the choicest Tea-scented Roses, only three of which are in your list, viz., Mme. Jean Dupuy, Marie van Houtte, and Mme. Lambert. Other beautiful varieties which you would find suitable would be Anna Ollivier, Lady Roberts, Mme. Constant Souper, Alexander Hill Gray, Souvenir de Pierre Notting, Lady Plymouth, Mrs. Hubert Taylor, Mrs. Myles Kennedy, Niphotos, and White Maman Cochet. To cover the wall fairly quickly such varieties should be planted about 1 yard apart, and it would be advisable to plant any dwarf Roses in front, at least 2 feet away, or even 3 feet if the border is fairly wide.

No harm would result from using fresh stable manure, provided it is, as you suggest, buried in the bottom spit of soil, where it would not come into close contact with the roots of the plants, but where it would be available for their future use. We would advise you also to add a sprinkling of basic slag to the lower spit of soil at the rate of 6 oz. to the square yard. Your soil, not being very rich, you would do well to give the plants a little immediate help, and this can be supplied most quickly and conveniently in the form of bone-flour, a perfectly safe and easily-assimilated Rose food. After planting the trees, form a small cavity around each one and throw in a handful of bone-flour, finally covering this up with soil. The subsequent rains will wash this food down to the newly-forming rootlets and the plants will be wonderfully benefited thereby. In March the newly-planted bushes should be cut down to within a few inches of the base, thus forcing the bottom eyes into growth, the result being a framework of sturdy young limbs.

NOTES AND REPLIES.

Orange-fungus on Roses (L. I. O.).—All the leaves lying under the bushes should be collected and burned. The plants that have been attacked should be thoroughly wetted with 2 oz. of sulphate of copper dissolved in 3 gallons of water in the spring before the buds open. If the disease still shows itself spray with weak Bordeaux mixture and pick off the affected leaves.

GARDEN FOOD.

NOTES AND REPLIES.

Celery crisp and good.—Seeing your question respecting crisp eating Celery, I have ventured to send you two or three heads of our Celery, which is, I think, crisp and not coarse. It was grown from seed supplied by Messrs. Fidler, and called Fidler's Prize-winner. I regret that your question did not come about a week ago before we had finished our early crop, which I think was the best Celery I have ever tasted—Sutton's White Gem. It has all the attributes you ask for, and has a good nutty flavour. We find here that it is better not to plant Celery too deep in our soil, so that the roots are in the water all the winter. I wish we could have sent you some heads of White Gem, but we have none left now.—E. W. H., *Lingfield.*

—“W.” asks for name of a good Celery. He would find that old variety Leicester Red of quite excellent quality and flavour. The flesh is quite white. I think decay in the centre is perhaps caused by insufficient care in preventing soil from being enclosed during the first earthing up.—C. B. ROBINSON.

Autumn-sown Onions.—As the winter store will be depleted all too soon this spring it is necessary to get the forwardest plants raised in autumn planted without further delay on a sheltered piece of well-manured ground. This will be made firm and then raked level. Sufficient ground only to allow of a dozen rows being planted will be so treated at a time, then if rain should fall the remainder of the plot will take no harm. A trowel is preferred to a dibber for planting, as the roots are spread out more widely, which gives the plants a much firmer root-hold, while they get away more quickly afterwards. Firm planting being so essential, the soil, after the roots are properly covered in, is trodden lightly round the plants. As the bulbs of the varieties grown attain a large size when mature the major portion of the plants will stand 9 inches apart in the rows, which will be 1 foot asunder. Those planted at 6 inches apart will be required for use before they become fully grown. The remainder or smallest of the plants will be utilised for setting out a few weeks hence on a more exposed plot of ground. These will form a successive supply and last till near or quite the end of the year.—G. P. K.

Vegetables over-boiled.—One of the mistakes commonly made is over-boiling green vegetables. In that way they lose their crispness and true flavour, and also the natural salts which make them wholesome. The Cauliflower over-boiled becomes so much pap and is useless as food. Experiments which have been made with animals show that over-boiling lessens digestibility. Our country is richer in the Brassica tribe than any other perhaps. In the right season some of these are very pleasant and wholesome food, as some of the Kales that bud in the spring. Pouring melted-butter or sauces over such things is a mistake, as in the case of Seakale and sometimes Brussels Sprouts. If sauces are required with such things a little fresh butter or gravy is usually at hand. Even vegetables like Spinach, which are reduced to a finely-cut state, may be spoilt by over-boiling.

Seakale and its use.—This is a product of our British gardens, and rarely in use in Continental Europe, a further reason, if needed, for our making good use of it. It is often over-cooked and messed over with melted butter. The best way is to serve it simply, and not over-boiled, as

that deprives us of the wholesome salts of the fresh shoots. If anything in the way of sauce is desired to go with the Kale fresh butter or gravy may be used. The wild plant on our coasts is well worth looking after by those who are near the sea; the rising shoots are quite good unblanched. It is of easy culture in the farmer's garden and is quite as good if brought on with leaves or loose litter as grown in the usual forced way. It is sweeter in taste. It may even be eaten without blanching as it bursts up.—W.

Potato Langworthy.—My Potatoes having failed this year, and even an appeal to Messrs. Judd and Malin, of Jermyn Street, having led to no good result, I gave Potatoes for baking up as hopeless. Then comes in from the garden the Langworthy, which, to my surprise and pleasure, is in fine condition, and, as I think, the best of all Potatoes to eat. If it is good this year we may count on it for any year, and all who care for good flavour more than appearance should try it. But looks are in its favour, too, because instead of being a bloated aristocrat of Potatoes it is of medium size and somewhat slender in shape. There are so many new varieties of Potatoes being sent out that it behoves all who care for flavour first to find out those Potatoes that have it.—W.

Apple Orleans Reinette.—Messrs. Bunyard send me from Maidstone fruits of this, which seems to me far above the ordinary Apple. It is good to look at, juicy, and of excellent flavour. I am now busy planting a group of it, and advise others to do the same. As to Cox's Pippin being the best Apple in the world, this is very far from being the truth. The Orleans Reinette is an old Apple and long known in our land, but lost among the number of varieties. The flavour is like that of a good Ribston and the flesh is as tender as that of D'Arcy Spice. I am glad Messrs. Bunyard have not rechristened this fine fruit after themselves. Giving new names to good old fruits is not an unknown practice and is no credit to our fruit-raisers.—W.

Corn salad.—To those who only have the green form of the above the new variety with a golden heart will come as a positive revelation. I do not think the quality of the salad is altered, but the appearance is most attractive, leading one to expect a blanched heart as in a Cos Lettuce, but caused by the golden colour of the inner leaves. It makes a very pretty garnish to any cold dish. I bought it under its French name of Mâche from a French firm last year. If I cannot get it this year I shall try to save seed if it is not all eaten first! I think it was called Mâche à Cœur dorée, or blond dorée.—A. MARTINEAU.

Apple Delicious from America.—I have been fortunate in obtaining in a local shop a sample of this Apple, and I consider it is very well named. It is an Apple of an unusual type of flavour, one more example of the possibilities inherent in the Apple. If it crops and thrives in this country it is an Apple that will please. I have found the flesh soft and Pear-like and very digestible. It reminds me in all but shape of a well-grown ripe James Grieve Apple.—W. J. FARMER.

Apple Blenheim Orange.—This Apple, grown under good conditions in the British Isles, is, I suppose, our best general-purpose Apple. For cooking it is delicious, requiring no sugar. For the dessert it is also most excellent, only put in the shade by Cox's Orange Pippin and a few similar Apples. Why do we grow rubbish when we have so many good old trusty Apples better worth the care of sensible people? I have not found overseas Blenheims at all equal to British Isles grown fruit, though they are also good in their way.—W. J. FARMER.

OUTDOOR PLANTS.

BUCKHURST PARK.

THE illustration gives a good idea of the climbing plants and Rose-beds which furnish one side of the bowling-green at Buckhurst Park, Sussex. Apart from its great value as a home for plants, the wall shown forms the support of a walk running parallel to the top of the wall itself, being also supported in its turn by wide buttresses, one of which, it will be seen, is used—by means of protruding steps let well into the wall—as a pathway to the higher level.

The whole plan is well conceived, each buttress being devoted to some choice subject, such as Vine, Escallonia, Clematis, etc., which it was pleasing to observe were allowed to hang in a free and elegant

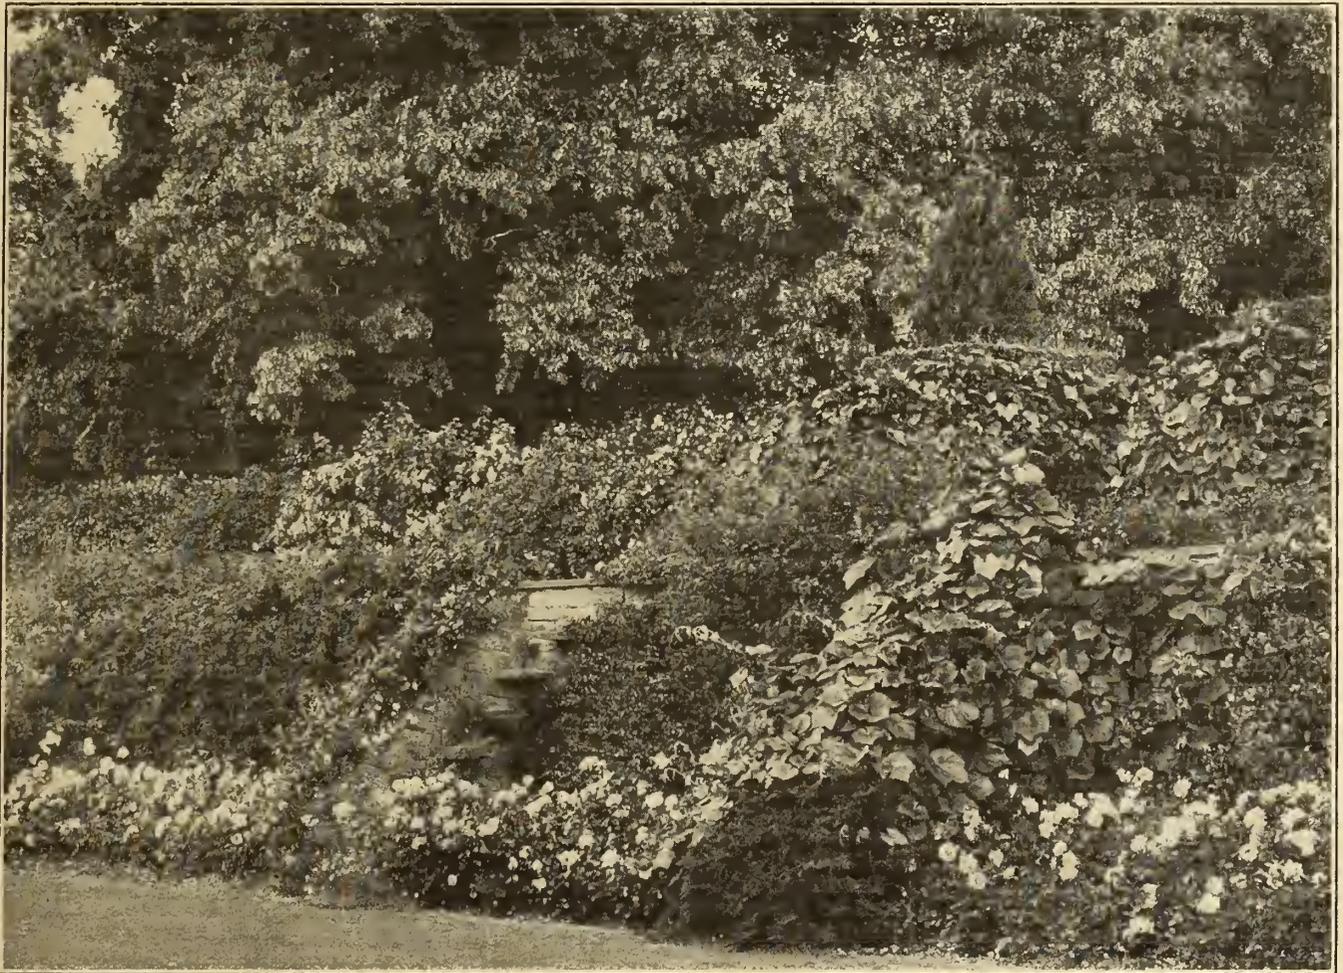

plants and are every whit as easy to grow as any of the others. *C. esculenta* is among the least effective, and I quite agree with Mr. Cornhill in his comparatively low estimate of this. It is, however, finer by the side of a stream or pond than in the mixed border.—S. ARNOTT.

HARDY FLOWER NOTES.

CROCUS IMPERATI.—What a pleasant little flower this is. I have it at the foot of a Douglas Fir, which has been trimmed up some 8 feet with a Holly hedge on the east side. There, in the mild January days, its pretty blossoms have expanded. A precious little hardy flower this, so easily accommodated, and within reach of the amateur of modest means, but so seldom seen in villa gardens.

HARDY CYCLAMENS.—In the same position *C. neapolitanum* is perfectly happy.

cutting, also plantations of *Anemone apemina*, *A. Robinsoni*, *A. ranunculoides*, and *A. nemorosa plena*, which I want to extend as much as possible. I began this work early in December, and it is curious to note how the worms have drawn the leaves under. In the case of a bed of *Anemone* and Tenby Daffodil they have almost disappeared. This seems to be the natural way by which plants retain their power. The foliage falls, the worms draw them in, utilize them in some way, and resurface the soil with their excrement. And so the work goes on from year to year when Nature has her course. It is only when man interferes with this natural process, and, worshipping at the shrine of tidiness, carries away this natural food, and has then to replace it with some form of manure. Many a beautiful hardy plant, shrub, and tree

A corner in the garden at Buckhurst Park, Sussex.

way. Rose-beds, each containing a distinct variety, fill the veritable "sun traps" which are thus formed between these imposing supports.

The Roses looked remarkably well, and in this position gave a bountiful and lasting display of choice flowers. E. M.

Camassias.—Mr. Cornhill's appreciation of *Camassia Cusicki*, at page 58, is well deserved. The *Camassias* known as *Leichtlini* hybrids are also much to be commended. Whatever their parentage may be they are superior to the typical *C. Leichtlini*, which has creamy-white, rather dull flowers. The hybrids are variable and give us plants with flowers which range in the respective individuals from pure white, through light and deep blue, to purple. They are excellent border

Some bulbs were planted there some twelve months ago, and they have such a nice appearance that I have filled up round the tree stem with several dozen good flowering bulbs, the last of some hundreds of seedlings raised some four years ago. Very few things which combine beauty of foliage with profusion of bloom will thrive in soil that is permeated with tree roots, especially those of the Fir, so that some of your readers may be pleased to know that this *Cyclamen* can be relied on to carpet the soil with handsome foliage and produce its flowers under such adverse conditions.

MULCHING WITH LEAVES.—Having collected a fair quantity of Oak-leaves it occurred to me to use them as a mulch instead of storing them. I covered some beds of Daffodils which I grow for

would flourish and show their true form if the fallen foliage were allowed to carpet the ground instead of being raked off.

GLADIOLUS SAUNDERSI.—I have this year been surprised to see how early in the year this species begins to push out new roots. I transplanted some bulbs in the middle of January, and white roots were already pushing out from them some weeks earlier than I should have thought possible. In my light soil this species will flourish for several years undisturbed; in fact I have had it now quite ten years in the same place. In some years there has been a score or more of flowering spikes, in others only two or three, and in one year not a single blade of foliage appeared. The ground was forked over and other things planted, when a numerous

colony of small plants appeared, which bloomed well the following year. I thought they were seedlings, but probably they came from bulbets formed at the base of the bulbs, which Gladioli growers call spawn. This spawn is eccentric in its formation, being numerous on some bulbs, whereas others will be quite bare. This year the spawn is unusually numerous, and I have simply sown it in the ground with the old bulbs. In this way this species renews itself from year to year, the bulbs that die, either from age or some other cause, being replaced by the young generation. I consider this *Gladiolus* a very valuable garden plant, for evidently it is only necessary to give a bulb or two good culture for a season in order to ensure the colonisation of that particular spot in a highly effective manner.

Blythe, Surrey.

J. CORNHILL.

HARDY FERNS AND FLOWERS IN WINTER.

READERS should be grateful to "Kirk" (page 16) for drawing attention to the injury inflicted on hardy Ferns in winter by the desire for tidiness and the consequent removal of old fronds. The question of the retention of old foliage is worth considering by those interested in hardy plants, and in those which just come under the suspicion of being a little tender. It is a subject to which I have given some thought and study. From what I have noticed I am satisfied that the loss of certain plants would be less frequent if the old foliage were allowed to remain on them during winter. Take, for example, some of the *Kniphofias*. In certain places these are liable to perish in some seasons, this being largely due to the removal of the leaves in winter to give the borders greater tidiness. As a matter of precaution it is not safe to remove those old leaves until all danger from severe spring frosts is past. One year I had a painful experience, caused by the removal of the old leaves being followed by an unusually severe late frost. As the result, some twenty clumps which had had the old foliage removed were killed. It was a grievous disappointment and taught me a lesson not likely to be forgotten. It is much safer for those who live in a district with a variable climate and danger from late frosts to retain the old foliage on many plants until spring has well entered upon its course. There is, certainly, a golden mean between too early and too late removal of the old foliage, especially where old, stiff stems are allowed to remain during winter. If the latter are left too long there is a danger lest the young shoots should be injured or broken off.

The general principle is, however, due to the conviction that in many cases utility is subordinated to winter tidiness, and plants sacrificed in consequence. In many instances, also, one of the means of natural manuring open to plants through the decay of their old growths is removed and additional supplies of fertilising material rendered necessary. I once followed a series of experiments made as to the effect of the removal of decaying leaves from the soil beneath deciduous trees. The results appeared to show that the trees which had their leaves removed for the sake of tidiness were in time less vigorous and healthy than those whose decaying foliage was allowed to remain. Apart, therefore, from the protection afforded to the plants by the old foliage, there is the question of manual supply to consider. Is it not the case that the premature removal of the old fronds of Ferns deprives them of a proportion of their natural nourishment?

A. S. M.

NOTES AND REPLIES.

Treating a slope.—At the end of my garden and sloping down towards the south I have a bank with a sandy subsoil and a fairly quick fall of 30 feet. The soil is very shallow, and as the slope is fairly sharp it is very dry in the summer. No doubt, a scheme of terraces would be the best thing to carry out, but this would cost too much money. I should be greatly obliged if you could let me know if there is anything I could grow on this bank which would spread quickly and thrive in spite of the conditions as described.—WILL MELLAND.

[The very shallow soil, the sharpness of the slope, and the southerly aspect are all against success unless special means be taken to improve the soil. By taking out soil to 3 feet deep and replacing it with good, sound loam, stations may be made for trailing (*Wichuraiana*) Roses, Clematises, *Cotoneaster*, and like subjects. The real question is what are you prepared to do to make it a success? As the matter now stands it is very much a question of ways and means, and so far as we understand your letter something only of a temporary nature is required. If this is so the position might be strewn with annuals if that would be in keeping with the environment, about which you say nothing.]

Elwes's Snowdrop.—*Galanthus Elwesi* is one of the most variable of Snowdrops, and those of us who have received it from different districts in the East have been surprised to observe the remarkable difference in its character. Certain forms are handsome, but others are exceedingly poor. Among the finest is the Cassaba form, the variety known as *G. Elwesi robustus* being also very fine. I do not care for the one named *G. Elwesi unguiculatus*, with claw-shaped segments, and some of the other collected forms are really poor. The Giant Snowdrop, as it is frequently called, often appears lumpy to me when compared with *Galanthus nivalis*. The flowers are frequently too large for the length of the stem, and hang less gracefully than those of *G. nivalis*, even under the same conditions, and I do not think it is so well adapted for naturalising. The late Mr. James Allen appears to have found it do best in very light soil. A point which deserves consideration is that of shelter, and this Mr. Allen laid some stress upon. He told us that it wanted the most sheltered spots in the garden, as otherwise the top-heavy flowers suffered from the wind and their beauty was soon destroyed. It is this top-heaviness which is the only defect of *Galanthus Elwesi*.—ESS.

Crocus stellaris.—When open this cannot well be distinguished from a number of other yellow Crocuses, but in the bud it is charmingly marked with a feathering of from three to five bronze lines. In the best varieties this feathering is very pronounced. As Maw remarks, *C. stellaris* "closely resembles some of the old garden forms of *Crocus aureus*, but differs from them in having a reticulated coriaceous tunic." It is an interesting Crocus in several ways, one of them being the fact that it has never been found wild. Another is that it never produces seeds. This year it was in flower with me before the end of January.—DUMFRIES.

Lenten Roses.—These are now in bloom (February 5th)—somewhat before their usual time. I have a fine plant at the foot of an Apple-tree, where it blooms freely every year. In one garden I know in Camberley Lenten Roses thrive well in large masses under deciduous trees. The only help they have is an annual dressing of leaf-mould. When cut the flowers last well.—JOHN CROOK.

Aquilegia cerulea Mrs. Nicholls.—I was impressed with this Columbine in a neighbouring garden last year. It was very free, and the flowers were not only longer spurred, but larger than I recollect to have seen in other instances. It is a great improvement on the old *A. cerulea*, and reminded me of an exceptionally vigorous *A. Stuarti*, which it much resembled.—KIRK

CHRYSANTHEMUMS.

SOME OF THE BETTER SINGLES OF THE PAST SEASON.

The Floral Committee of the National Chrysanthemum Society held several meetings during the autumn of 1915, and a large number of novelties was submitted to it. A Chrysanthemum to gain the first-class certificate of the National Chrysanthemum Society must obtain a majority of at least three-fourths of the members of the committee present, so readers will appreciate the value of any new sorts obtaining a first-class certificate or a commendation. The following in singles are some of the better novelties of the past season:—

YELLOW MERSTHAM JEWEL.—This is a beautiful golden-yellow sport from Merstham Jewel having medium florets, grooved, and a moderate disc. First-class certificate November 11th.

PICOTEE.—A distinct and refined single about $4\frac{1}{2}$ inches in diameter. The florets, of which there are several rows, are flat, stiff, and pointed, and their colour may be described as edged and suffused rose on a white ground. First-class certificate November 11th.

ARTHUR SEARLE.—A beautiful variety, the flowers quite $4\frac{1}{2}$ inches in diameter with three rows of medium to broad florets arranged in fairly even fashion round a nicely-proportioned disc; colour, wine-red shading to white at the base of the florets. First-class certificate November 11th.

MONICA MITCHELL.—A beautiful large-flowered single fully 5 inches in diameter. There are three rows of fairly broad, recurving florets and a moderate-sized disc. The colour is rosy-carmine—some say carmine-crimson—with a narrow yellow zone round the disc. First-class certificate November 21st.

ARISTOCRAT.—Each flower has about five rows of florets which are fairly broad and recurve in very even fashion. The disc is of moderate size, which is a great advantage; colour, bright yellow. First-class certificate November 21st.

RIFLEMAN F. KENT.—A free-flowering single about 3 inches in diameter, having three to four rows of medium florets fairly evenly arranged. It is excellent in spray form; colour, golden-fawn. Commended November 21st.

DECEMBER BEAUTY.—A fine single about $5\frac{1}{2}$ inches across. There are three or more rows of fairly broad florets neatly arranged around a small disc; colour, reddish-bronze, shaded yellow at the tips of the florets. First-class certificate December 8th.

YELLOW PERFECTION.—For so late in the season (Christmas) this is a truly beautiful large-flowered single. The florets are fairly broad, recurving, and drooping, and of charming form. The flowers are each fully $4\frac{1}{2}$ inches across, the disc small, and the colour a rich tone of bright yellow. First-class certificate December 8th.

SNOWSPRAY.—A beautiful single of attractive form and handsome as a spray variety. Each blossom is about $3\frac{1}{2}$ inches in diameter and pure white. Commended December 8th.

CRIMSON VELVET.—This is an ideal flower of the type. The florets are of good length, narrow, and slightly twisted, but arranged in the most even fashion. The flowers are each 5 inches in diameter and the colour is crimson with a broad yellow zone round the disc. First-class certificate December 8th.

NORMAN PEARSON.—Another attractive single about 4 inches across, having three or more rows of florets of medium breadth;

colour, chestnut-red overlaid with gold. First-class certificate October 25th.

TOM WREN.—This will be valued because of its comparative earliness. The florets are of good length, stiff and broad, and the colour is pure white. There are several rows of florets. Commended October 25th.

PHYLLIS COOPER.—A single having several rows of stout, evenly-arranged, fairly broad, pointed florets. The colour may be described as rich golden-yellow. First-class certificate October 25th.

MASTER A. EWEN.—This variety was first shown in 1914, but on the present occasion its quality and beauty were unquestioned. The florets are long, broad,

TREES AND SHRUBS.

VIBURNUM MACROCEPHALUM.

This Chinese plant is known by its sterile-flowered form, which has been grown in English gardens for sixty years, but is not very common on account of its semi-tender character. The heads of flowers, which are larger than those of any other kind, bear a striking resemblance to the heads of sterile-flowered Hydrangeas, and last in good condition for a considerable time, the colour being creamy-white. The leaves may be evergreen or deciduous, according to season, but they are usually retained in the warmer counties. About London and

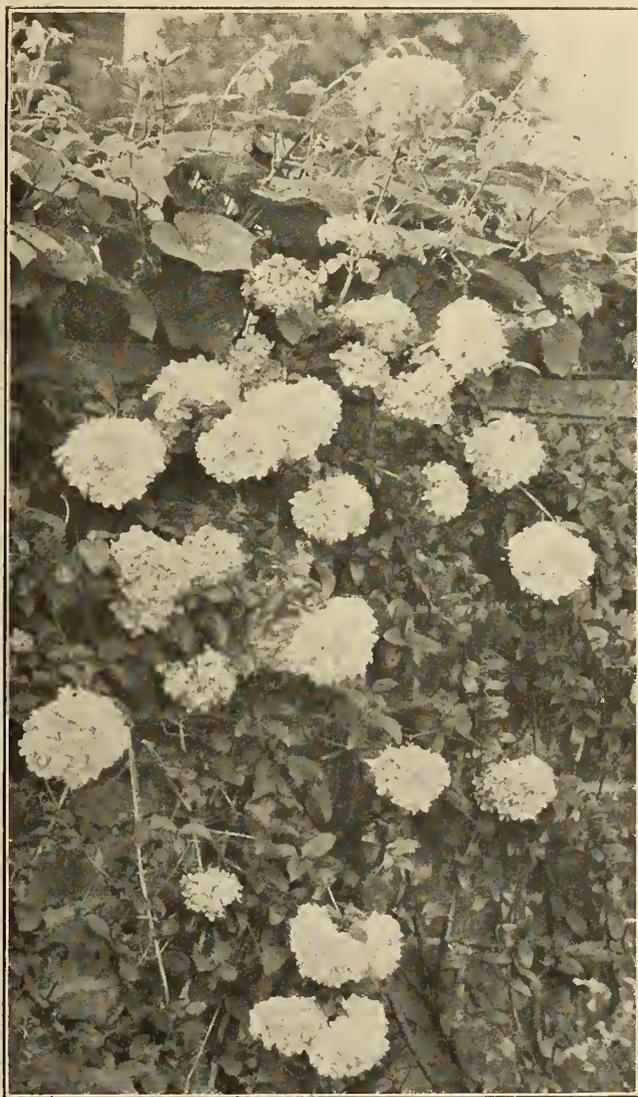

but in a series of examples there may be intermediate forms. The flowers are conspicuous, chiefly by the mass of yellowish stamens borne several together from the leaf-axils and are usually at their best during late autumn. E. Gunni is one of the hardiest of Australian trees and may be grown in many parts of the country, good examples being reported from the eastern counties, the south of England, and also from Scotland. It should be placed in a permanent position whilst quite small.—D.

THE GARDEN FLORA OF JAPAN.

It is well that garden-lovers of this country should treasure the name of Dr. G. R. Hall for the plants he introduced—*Lonicera Halleana*, *Magnolia stellata*, *Malus Halleana*, and others—are indispensable. It was in March, 1862, that Dr. Hall returned from Japan and handed over his rich collection to Samuel Parsons at Flushing, Long Island, for propagation and distribution. But previous to this Francis Parkman, of Jamaica Plain, Boston, had received a consignment of plants from Dr. Hall, through Mr. Gordon Dexter, and among others was the famous *Lilium auratum*, which flowered for the first time in America in July, 1862. In the early sixties Thomas Hogg visited Japan in the interest of Samuel Parsons and introduced in 1865 many plants including *Magnolia obovata*. Another American, Professor W. S. Clark, who went from Amherst College, and developed the Agricultural College at Sapporo in Hokkaido in the early seventies of the last century, sent, in 1876, seeds of many valuable plants, such as *Magnolia Kobus*, *Cercidiphyllum japonicum*, *Syringa japonica*, *Actinidia polygama*, etc., etc. In the Arnold Arboretum and elsewhere many fine specimens raised from his seeds are growing to-day. Three Englishmen, John Gould Veitch from early spring to autumn of 1860, Robert Fortune from the autumn of 1860 to the summer of 1861, Charles Maries from 1877 to 1880, collected extensively in Japan, and each added to gardens treasures beyond price. During the same period, and in the early eighties, various foreign amateurs in Japan sent to their friends in Europe such valuable plants as *Vitis Cointetiae*, *Prunus Sargentii*, *Rosa multiflora*, *Rosa Wichuriana*, etc.

The pioneer work was supplemented in a remarkable manner by Professor Sargent, director of Arnold Arboretum, who visited Japan in 1892. His predecessors in Japan had enjoyed a virgin field, but as an offset to this Sargent had the advantage which full knowledge of a subject gives. He knew not only the Japanese plants already in cultivation in the Occident, but was also fully acquainted with the forest flora of Japan, and the result was that a great number of beautiful and hardy trees and shrubs was added to our gardens. He introduced, among other plants, all the Japanese deciduous Oaks, certain Hornbeams, Birches, Alders, *Picea Glehnii*, *Abies sachalinensis*, *Malus zumi*, *M. Tschonoski*, *M. Sargentii*, *Kalopanax ricinifolium*, *Enkianthus campanulatus*, *Acer nikoense*, *A. Miyabei*, *Rhododendron Kaempferi*, one of the most beautiful of all shrubs hardy in New England, and many other valuable plants.

In Japan the Pine, the Bamboo, and the Plum-blossom (*Prunus Mume*) are emblematic of long life, strength, and happiness, and a love of flowers is a dominant characteristic of the people. This love is spontaneous and fundamental, and is one of the virtues of the race which appeals forcibly to the most casual visitor. The arrangement of flowers for house decora-

Flowering shoots of *Viburnum macrocephalum*. From a photograph in a Surrey garden.

and recurving; colour, golden-bronze. Commended October 25th.

MIRANDA.—A terra-cotta sport from the well-known Portia. All the fine characteristics of the parent are represented in this new sort. First-class certificate October 25th.

BERTHA FAIRS.—In this the florets are of good breadth and very evenly disposed round a disc of moderate proportions. It is an ideal flower, the colour a golden-fawn with a yellow zone round the disc. First-class certificate October 25th.

Mrs. HAROLD PHILLIPS.—This is valued for its lovely mauve-pink colour. There are two rows of medium-sized florets, and the flower is about 4 inches across. Commended October 25th.

E. G.

farther north it is well to give it a place against a wall.

The Cider-tree (Eucalyptus Gunni).

For the milder parts of the country there are several kinds of Eucalyptus that can be planted with advantage, one of the best being E. Gunni. Plants upwards of 60 feet in height have been recorded in the British Isles, the trunks being from 12 inches to 18 inches in diameter. It is a very variable tree, the leaves of the juvenile example differing very widely from those of the mature specimen. In the former case they are usually rounded, and in the latter instance Willow-like. Sometimes specimens taken from two trees may vary considerably in the size and shape of the leaves,

tion is one of the three essential parts of every lady's education, and, be it said, it is an accomplishment in which all the people excel in a most artistic manner.

Here and there throughout the land are places famous for their Plum-trees, Cherry-trees, Wistaria, Iris, Paeonies, Azaleas, Maples, Chrysanthemums, Pines, Cryptomerias, and so forth, and in season people flock from far and near to feast on their beauty.

The floral seasons of Japan commence with the Ume (Plum-blossom, *Prunus Mumo*) in January, and close with the Chrysanthemum in November and December. In March and in April, according to climate, the Cherry-trees blossom, and this is the season par excellence. The Japanese recognise a hundred and more varieties of Cherries with white, yellow, pure pink to deep rose blossoms; some small shrubs, others large trees, with wide-spreading crowns; some have pendent, others quite erect branches, and all are very beautiful. Cherry-trees are wild in the woods and thickets throughout the length and breadth of Japan, and are everywhere planted in vast numbers—in temple and castle grounds, in park and garden, in the streets of the cities and alongside the highways, and by pond and river side.

I never knew the full glory of the Wistaria until I saw it in Japan. There it is not only wild in profusion, but is abundantly planted by the sides of the ponds, ditches, and streams, and trained over arbours and trellises. There are numerous varieties and on one I measured racemes of flowers 6½ inches long. These were not mere individual examples, but there were thousands upon thousands of them equally long.—E. H. WILSON in *Gardeners' Chronicle of America*.

NOTES AND REPLIES.

Rhododendron Nobleanum.—Please tell me the name of the Rhododendron, flowers of which I send you. It is now in full bloom. It flowers always about this time, but is far better than usual. Please say best way to layer it.—C. A. S., *Curramore, Broadford, Charleville, Co. Cork*.

[The name of the enclosed specimen is *Rhododendron Nobleanum*, a hybrid raised in the first half of the last century between the Himalayan *R. arboreum* and *R. caucasicum*. As a rule the habit of the plant does not admit of the branches being readily bent down for layering, but as you suggest that method of increase perhaps some branches of your specimen may be available for treatment in this way. If such is the case the shoot must be brought down to the ground and pegged securely in position. Of course, a hole must be taken out in which a portion of the stem is to be buried. Previous to this that part of the branch which is to be covered must be slit lengthwise, after the manner practised in layering carnations, placing a small stone therein to keep the slit open. The free end of the shoot must then be tied upright to a stake in order to prevent it moving in any way. The buried portion should then be covered with sandy soil, as this will encourage the formation of roots. It is very essential that this soil be kept in a regular state of moisture, as the rooting will be greatly assisted thereby. It will take two, or even three, years before the layers are sufficiently rooted to be detached from the parent plant.]

New Index and Binding Cases for completed Volume.—The Index to Volume XXXVII. of *GARDENING ILLUSTRATED* is now ready (price 3d., post free 3½d.). The Binding Case for the same volume is also available (price 1s. 6d., by post 1s. 9d.). The Index and Binding Case can be obtained from any newsagent, or from the Publisher, 63, Lincoln's Inn Fields, London, W.C. If ordered together, the price of the Index and Binding Case is 2s., post free.

ROOM AND WINDOW.

WINDOW GARDENING.

PRIMROSES.—Those who may have nice plants of these should put some into pots. They must not be put into a constantly-heated apartment, as they cannot bear artificial warmth, which causes the foliage to draw up, the blooms being weak and very deficient of size and colour. In a cool room they are at home and will produce blooms of pristine freshness at a time when cold winds, frosts, and stormy weather prevail in the open. Taken up now and potted in nice free soil they will suffer no check. After blooming they can be planted out in a shady place, and may be used again the following year.

SCILLA SIBIRICA.—The little Siberian Squill is charming in pots, being so distinct in colour from spring-flowering bulbs generally; and as it can now be purchased at a cheap rate the window gardener can obtain a nice effect for a few pence. A dozen bulbs in a 4½-inch pot will have a delightful appearance, forming a lovely blue carpet.

TRITELEIA UNIFLORA.—When this made its appearance a good many years ago I was not certain as regards its hardiness and fitness for the open ground, and therefore potted the bulbs. I was so pleased with their appearance that I continued to grow them in this way for several years. A dozen bulbs can be put into a 4½-inch pot, and, treated thus, well-grown specimens have a nice appearance.

SEED-SOWING.—It is a fact, but one not generally recognised by window gardeners, that many things can be raised from seeds early in the year in an ordinary living-room. I know of an instance which shows what may be done in this way. About 200 Tomato plants which are required for planting out in a cool house in May are raised in this way. The seeds are sown in small pots in the latter end of February, in this manner there is no necessity for potting off. The young plants go away without check until the time comes for them to be planted out. Several seeds are put into each pot in order to make sure, as sometimes seed is rather wanting in germinating power and some kinds do not come up so well as others. The pots are stood in boxes which are covered with a pane of glass, which is removed when the young plants appear. Later on they go into a cool house under a handlight. It is well to know that many seeds may be raised in this manner, for thousands of amateurs have not the convenience of a constantly-heated glasshouse in early spring. There are some things that the amateur sees in seed lists that he would like to try, but he knows that they are forbidden to him simply because he cannot raise them early enough to obtain a good long season of growth. In the manner above-mentioned many things may be forwarded, but I do not advise beginning before the first week in March. There is another way which I have practised, not only early, but during the summer season, and which I have found very convenient. It frequently happens that one wishes to sow a few seeds of some particular thing, and there is no frame empty, the only place being an airy greenhouse or the open air. The seeds are sown, say, in a 2-inch or 2½-inch pot in the usual manner, this being stood in one a size larger. A piece of paper is laid on and a pane of glass on this. In this way the pot containing the seeds is screened from the direct influence of sun and air, and uniform moisture can be much more easily secured with much less attention in the matter of watering. Fill the seed-pot with nice free soil

to within ½ inch of the rim, give a gentle watering, allow it to stand an hour, and then fill nearly to the rim with fine, well-sanded soil. Press the seeds into this, cover very thinly, and gently moisten it. In this way very little water will be needed and germination will be freer and more uniform.

BYFLEET.

NOTES AND REPLIES.

Cyclamen blooms flagging when cut.—I shall be glad if you can tell me the reason why my Cyclamen blooms droop as soon as cut for house decoration. They are grown in a temperature of from 50 degs. to 55 degs., and are potted in a compost of loam, leaf-soil, sand, and cow-manure, and are in very good health. Last year the blooms lasted a good week when cut for house decoration, and they had the same treatment, so I cannot understand why the blooms should die so soon this season.—B. WILDE, *Roundwood Lodge, Baidon*.

[Your cultivation appears to be right, with the exception of temperature, which for the day may well be from 3 degs. to 5 degs. higher, accompanied by a fair amount of ventilation. Draughts must be avoided, and for this reason air is best admitted either beneath the stage or in such a manner that before reaching the plants it becomes warmed. Flowers grown under these conditions will remain fresh for a week if pulled—not cut—from the plants as soon as they become fully expanded. After they have been open a few days they will, if placed in a room where the atmosphere is close and the temperature above the normal, particularly at night, then droop unless the precaution is taken to slit the lower end of the stem in an upward direction for about 2 inches. This remedy we have, under such circumstances, never known to fail, and, therefore, advise you to give it a trial, as we think it will help you out of your present difficulty.]

The Snake's Beard (Ophiopogon) as a window plant.—One of the most valuable of window plants of graceful growth is the Snake's Beard (*Ophiopogon Jaburan*), introduced from Japan in 1830. It is hardy, or nearly so, in many places, but in the north will not stand severe winters, and has to be grown under glass. It is worthy of this, because of its graceful, arching leaves, from among which rise the spikes of blue flowers. The variegated variety is even more valuable for the home, because of the brightness of its foliage.—ESS.

VEGETABLES.

NOTES ON ONIONS.

ONION SETS.—In places where the Onion maggot makes the culture of spring Onions almost impossible planting very small sets is one way out of the difficulty. I had never practised this method. It was quite new to me until last year. It happened that some seed of James's Long Keeping was sown quite late in April, if I remember rightly. The soil was poor, and, through press of work, the young plants were much neglected, got very weedy, and made but little growth; in fact, they were hardly worth harvesting, the biggest being about the size of a Cobnut, many being no larger than Peas. Planted out the following season several inches apart they made nice bulbs, which would have been much larger had the ground been richer. I may add that these bulbs are keeping remarkably well, which is a real boon, Onions being so dear—up to 14s. per cwt. wholesale—and the Tripoli not keeping at all well this season. There is no doubt that good Onions can be grown with certainty in this way, but what I am not sure about is the right time to sow for the production of sets, as, if sown too early, they will be too big, and, instead of bulbing, will run to seed. Perhaps some of your readers have experience of this form of Onion culture and will give us the benefit of it.

SCALLIONS.—I fancy that this gardening term is pretty well extinct; anyway, it is

a long time since I have seen or heard it mentioned. In former days the supply of fresh, juicy Onion-tops was furnished by bulbs put out early in March, and these were termed Scallions. Some of the smaller bulbs were used for this purpose. I suppose that in those days the sowing of Onions to stand the winter was not practised. Abercrombie, who was the great authority on vegetable culture, makes no mention of this practice. I do not know when the Tripoli and Rocca varieties were first grown, but I suppose that it was owing to them that the planting out of old bulbs was discontinued. Scallions gave a supply of green tops some time before spring-sown Onions were large enough to pull, but what are now called winter Onions, if sown in August, come in much earlier. A grower in this neighbourhood has every year an acre of Ailsa Craig, which he disposes of in small bunches. I have wondered why he used this variety, the seed being considerably more expensive than that of the Tripoli and Rocca, but probably he leaves a portion to grow on, and Ailsa Craig keeps so much better.

SOWING.—By the time these notes appear, ground intended for seed should be dug up in rough lumps, the bigger the better. I shall be getting mine ready now (February 1st). The influence of frost on the soil thus exposed is very great, and ground treated in this way is in much better order for the reception of the seed than when dug later in the ordinary manner. On light soils one can scarcely err on the side of early sowing. March is too late, as the young plants do not get enough hold of the ground by the time dry weather comes. BYFLEET.

MANURE FOR POTATOES.

I HAVE about 2 acres of land—good, deep soil—on which for many years Turnips and Mangolds have been grown with patent manures. Last year Potatoes were grown without manure or fertilisers. This year it is proposed to plant Potatoes again. Will you kindly advise a good cropping variety, and the best chemical manures, and the quantity to use? Would malt dust be suitable? It is not easy to get stable-manure. Perhaps you can suggest some other crop, not entailing a great deal of labour?—C. EDWARDS.

[Under existing conditions we think you cannot do better than grow Potatoes again this season. Their cultivation will entail less expenditure in regard to labour than anything else at the present juncture, and as to the disposal of the produce there need be no apprehension felt on this score, as the demand when next autumn and winter arrive will in all probability be a heavy one. A few reliable and heavy cropping varieties are as follows:—Abundance, Up-to-date, Langworthy, Scottish Triumph, and The Factor. Whichever of these five you select we advise you to obtain fresh seed, preferably that grown in the past year in the north. With respect to manure, malt-dust is considered by some to be a good stimulant for Potatoes, but it is recommended that before applying it to the soil it is best moistened with liquid manure, tank sewage, or the drainings from cattle-sheds, and allowed to lie for a few days and ferment. From 25 bushels to 30 bushels per acre may be applied and dug in. A suitable mixture of chemical manure consists of superphosphate of lime, sulphate of ammonia, and kainit. For an acre you would require 5 cwt. of the first-named, 2 cwt. of the second, and 3 cwt. of the third. All three should be intimately mixed together, then evenly distributed over the surface and dug in. If, as may be the case, you are unable to purchase the kainit—for potash is very scarce now—you had better abandon the suggestion we put forward and purchase a Potato manure ready compounded from a reliable

firm of manure manufacturers. If the nature of the soil and the area to be manured are stated when ordering, a suitable mixture and the requisite quantity will then be sent.]

Seakale.—Continue to introduce batches of Seakale to the forcing-house in sufficient quantities to meet the demand. Seakale of the best quality is secured from roots forced in their growing quarters, and although this method gives more trouble, the growths so obtained are usually much stronger and more succulent. Special pots with covers are usually employed, but boxes or barrels will answer the purpose quite well. A small quantity of long stable manure, with some good Oak, Beech, or Spanish Chestnut leaves, will be needed to create the necessary warmth. A temperature of 60 degs. will be ample for the roots. The roots which were taken off when the early batches of crowns were lifted for forcing, made into cuttings, and tied into small bundles will now be placed in boxes of sand and put into cold frames, in order that they may be induced to start slowly into growth.—F. W. GALLOP.

BOOKS.

THE PRAIRIE SPIRIT IN LANDSCAPE GARDENING.*

MR. MILLER is doing his best to arouse the attention of the Illinois people to the charms of their own trees and shrubs, and also to the need of some picturesque design in their surroundings, and as the land there is mostly level he tries to point out how it can be made beautiful. Certainly it can. Our own Lincolnshire, and other level counties, prove it, and I would as soon plant in Lincolnshire, in a good soil, as in a hilly country in a poor one. Right planting is the whole question, and this book is a well meant and a successful effort. Some of the terms Mr. Miller uses he does so in the wrong sense. What is called a "prairie soil landscape gardening" is simply our English landscape garden art. There is no need for the word prairie. Again, the word "formal" is applied to the garden where the word garden is the old and right word; and the ugly expression "gardenesque" is brought in. Such words as these are of no good use, but confuse with needless complexity.

Illinois, like so much prairie country, is rich in native plants, and it is only right that men's minds should be awakened to their charms. The American wild flowers were grown in English gardens long before they were thought of as garden flowers in their own country.

Domestic architecture in Illinois, like much of our own, is "jolly" bad, and if the architects who built such houses are let loose in the garden the result can easily be told. We hear from Professor Sargent and others that the landscape architect has run amok in America in attempts at making the sham Italian garden in a country entirely unsuited to it. There the marble statues which the American millionaire provides have to be carried indoors in winter.

The illustrations in the book are very good. At one time the people of Illinois cut down their native trees without mercy, and later on, when they were able to afford it, they called in a landscape planter, who proceeded at once to plant again very often the trees they had cut down!

W. R.

* "The Prairie Spirit in Landscape Gardening," by Wilhelm Miller, U.S. Dept. of Horticulture, Landscape Extension, University of Illinois Coll. of Agriculture, Urbana.

THE WEEK'S WORK.

OUTDOOR GARDENING.

IN BLOOM FEBRUARY 10TH.—*Porsythia suspensa*, *P. spectabilis*, *Edgeworthia chrysantha*, *Yellow Jessamine*, *Coronilla glauca*, *Cydonia japonica*, *Winter Sweet*, *Andromeda* (in variety), *Rhododendron praecox*, *R. Nobleanum*, *Berberis* (in variety), *Daphnes* (in variety), *the Cornelian Cherry* (*Cornus mas*), *Ericas* (in variety), *Laurustinus* (various), *Gemsta hirsuta*, *Witch Hazels* (in variety), *Parrotia persica*, *Camellias*, *Corsican Hellebore*, *Lenten Roses* (in various colours), *Blue-eyed Mary* (*Omphalodes verna*), *Narcissus pallidus praecox*, *N. Tazetta*, *N. minimus*, *Aconites*, *Primroses*, *Violets* (in great variety), *Crocus Susianus*, *C. Imperali*, *C. Sieberi*, *C. stellaris* and others, *Snowdrops* (in variety), *the Carpathian Snowflake*, *Cyclamen Coum*, *the Greek Anemone* (*A. blanda*) (in various colours), *Anemone coronaria* (in various colours), *the Scarlet Windflower* (*A. fulgens*), *the White Wood Anemone* (*A. nemorosa alba*), *A. Hepatica*, *Saxifraga* (in variety), *Algerian Iris* (*I. unguicularis*), *Trilecia uniflora*, *Hyacinthus azureus*, *Scilla sibirica*, *Grape Hyacinth* (*Muscari botryoides*), *Corydalis cheilanthisfolia*, *Iberis petraea*, *Lithospermum rosmarinifolium*, *Scilla taurica*.

WORK OF THE WEEK.—Sweet Peas have been sown during the week. Two seeds are placed in a 3-inch pot filled with good sandy loam and stood in a warm-house. I prefer this method to sowing a large number of seeds in a pot or box, as they may be planted without disturbance, whereas with thick sowing it is almost impossible to avoid damaging the roots and giving them a severe check when planting out. To provide a succession others will be sown in the same way later on. Clematises on tripods have been thinned and pruned and the supports renewed by using Larch poles. The pruning of climbing Roses and other subjects is still receiving daily attention. Tree Lupinus raised from seed last spring, having grown to such an extent as to obstruct the free use of a path near by, have been cut into shape. The plants in tubs and vases intended for the decoration of the flower garden have been restaked and top-dressed with some good loam. A few plants of *Haberlea rhodopensis* have been planted in a very wet place at the foot of a high retaining wall, and a new Marsh Marigold has been potted into 6-inch pots and partly submerged in the Lily tank. A number of *Acer colechicum rubrum* (a fine tree for autumn colour) has been grouped at the back of the Heath garden and a batch of hardy Fuchsias has been planted at the base. These Fuchsias had occupied the same position for a number of years, and their removal has given space for extending the collection of Pampas Grass, to which a number of the variety elegans has been added. A small group of Butcher's Broom has been planted in the Heath garden, and a large specimen of the Mop Acacia (*A. mimosifolia*) has been removed to make room for some handsome flowering kinds of Apples. A number of *Aesculus Briotti* having come to hand a place has been given them near the carriage-drive, while a few have been planted along the ridge of an old lane.

Sussex.

SOUTHERN COUNTIES.

Protecting Apricots.—Owing to the mildness of the weather during last month the flower-buds on Apricot-trees are on the point of expanding. The buds are bold-looking—a sure proof that the wood

ripened well last autumn—and also very plentiful both on young wood and on spurs. The buds having therefore arrived at that stage when a few hours' sunshine will cause the forwardest to unfold, protection cannot with prudence be withheld any longer. Coping-boards must therefore be fixed in position, and poles for keeping the nets from damaging the blossoms fixed to the under-sides of the same and let into the ground 6 feet apart and 3 feet distant from the wall at the base. The nets used are of $\frac{1}{2}$ inch mesh, of which three thicknesses are suspended from the coping-board and allowed to almost touch the ground. These nets being so close in the mesh, afford much more protection from frost and cold winds than many imagine, while sufficient light penetrates to prevent the blossoms becoming at all injured. Further proof of the shelter afforded by the nets is always visible in the rapidity with which Lettuces planted at the foot of the wall start growing once they are suspended in front of the trees. Disease having killed off our own bees as well as those belonging to other people in the locality, the setting of the blossoms will have to be largely, if not wholly, left to chance, as exigencies of labour will not allow of this being performed by hand. So far the border is sufficiently moist right up to the base of the wall, but as the coping-boards and nets throw off a great deal of rain the portion so protected, *i.e.*, for a width of 3 feet, will soon begin to dry out and require water so soon as the fruit is set.

Outdoor Peaches.—These, fortunately, are not in nearly such a forward condition as Apricots, but as there will be more than enough to do as the season advances it will expedite matters to have everything ready for suspending the nets when such becomes necessary.

Ornamental Vines.—These, which are grown for effect only, should now be pruned and put in order for the season. As the engendering of a gross or unfruitful habit of growth has in this case not to be taken into consideration a little rotten manure may be forked into the border or near to the stems, especially in cases where a more vigorous production of wood is desired. Where this cannot be spared Vine manure or bone-meal can be substituted for it with good effect.

Wall creepers.—A commencement will now be made with the pruning and putting in order of these for the coming season. Jasmines, except the naked-flowered variety, which is yet full of bloom, *Ceanothuses*, *Tecoma capensis*, *Virginian Creeper*, and *Wistarias* will first have attention. As these oftentimes experience the full effects of south-westerly gales special care is bestowed on the tying of the stems and main branches to the wall.

Rose arches.—The final overhauling of the Roses on these will now take place, when a further thinning of the wood where it appears to be necessary or desirable will precede the fastening of the wood in a light and informal manner to the arches. All long, whip-like growths are merely tipped. This refers to the Rambler and *Wichuraiana* sections of Roses. A certain amount of spurring is also carried out in regard to climbing Hybrid Tea varieties. In course of time the roots exhaust the manurial constituents of the compost in which they were planted. The present is, therefore, a good opportunity to afford them assistance in the shape of a top-dressing of fresh soil enriched either with decayed manure or some suitable artificial fertiliser, or by forking in a proportionate quantity of the latter alone.

Strawberry planting.—Where this was not concluded last autumn the present

spell of open weather will afford a good opportunity for doing so. Although the plants will not bear this season there is the satisfaction of knowing they will carry a full crop another year, and, to make some amends for the loss of time involved, the ground in the meantime can be lightly cropped with anything that will turn in quickly. The Strawberry plants should be lifted with a good ball and planted with a trowel, finishing by treading the soil firmly round them.

Propagating.—As fast as cuttings can be had of *Lobelias*, *Chrysanthemums* (both for pots as well as of one or two varieties of which there is a shortage for outside borders), *Fuchsias*, etc., they are taken and put in to strike in heat.

Seed-sowing.—A pan of seed of *Cineraria stellata* Feltham Beauty sown now affords plants for flowering in December next. The same remark as regards sowing applies also to *Primula obconica* and *P. malacoides*, only in this case the plants will bloom in the autumn. *Torenia*s should also be sown now, and the same with respect to *Saintpaulia ionantha*. *Celosia pyramidalis*, when well grown, makes a good pot plant either for greenhouse or room decoration. It is best to raise two batches of plants, one now and another in a month or six weeks. The dwarf variety is preferred. *Clerodendron fallax* is a useful pot stove plant for autumn decoration. The seed should be sown now in a pan and the plants, when ready, potted into 60's. *Impatiens Sultan*, although anything but new, is valuable for room decoration. A stock is quickly raised either from seed or cuttings. Frequent pinching of the growths is necessary to secure nice bushy plants, and until this is attained the flowers must be suppressed. Seed for raising a new stock both of *Smilax* and *Asparagus Sprengeri* should, if it has not already been done, be sown at once.

Ferns.—The first batch of Maidenhair Ferns that were cut over a few weeks since and which are now pushing up new fronds is in just the right condition for potting. Clean pots and drainage are essential, and to the compost consisting of equal parts of loam, peat, and a liberal quantity of sand a sprinkling of old mortar-rubble broken fine is added. The remainder of the plants will be cut over and given a short rest in the course of a few weeks.

Leeks.—For these there has been a large demand throughout the winter, and provision for the growing of a large quantity of plants has to be made. For the earliest supply seed must be sown at once in a sunny corner.

Planting Seakale.—To obtain well-matured crowns for forcing early next winter cuttings should be planted at once in ground that has been thoroughly manured. The cuttings should be made from the stoutest of the pieces of roots saved when lifting took place last autumn. To distinguish the tops from the bottoms the former should be cut straight across and the latter in a sloping direction. A suitable length of cuttings is 6 inches. Cuttings to afford crowns for forcing later in the season will be planted next month. Planting is done with a trowel, the tops of the cuttings being left level with the surface of the ground. A handful or so of fine cinder-ashes placed over each to protect the young growths when they appear from slugs completes the operation.

Celery trenches.—Following the usual custom, these will be opened out the first opportunity. The trenches are 4 feet in width with an interval of 6 feet between them to receive the soil thrown out, which is formed into a flat-topped bank 4 feet

wide. On each of the latter, Peas are sown. The trenches, which take four rows of Celery, are taken out a full spit in depth. The bottom is then loosened with a fork, after which a good-layer of manure is placed thereon and covered with a couple of inches of the finer soil thrown out. Doing this now saves much valuable time later in the season. A. W.

MIDLAND COUNTIES.

Figs.—From trees on a south wall the materials used during the winter to protect from frost will be removed now and the necessary pruning carried out. Trees that are growing in unconfined borders require to be very carefully pruned or nothing but gross shoots, that will never ripen or bear fruit, will be produced. It is by far the better plan, in the case of Figs, to have the root-run restricted as to width and length. This may be done by digging a trench about 4 feet from the main stem, according to the size of the tree, severing all the strong roots and filling in with brick-bats or similar materials. By this means, and careful disbudding, well-ripened and short-jointed shoots will be ensured, and but little pruning at this season required. After the necessary pruning is completed the trees will be thoroughly washed with Gishurst compound, after which training may be done, arranging the shoots thinly and at equal distances over the wall space. If sharp frosts occur after the training is completed the growths will be protected by fastening Archangel mats securely over them. Trees growing in restricted borders should be afforded a top-dressing of loam and wood ashes, to which has been added a little bone-meal, mixing all together before use. This top-dressing should be made quite firm.

Birds.—A sharp look out has to be kept for bullfinches amongst the Gooseberry and Plum-trees at this season, for if left undisturbed even for a few days they will do much mischief. I have found that by spraying the trees at this date with Bentley's bird protector composition the mischief usually wrought by small birds has been lessened. The syringing should be repeated as often as necessary.

Caladiums that have been wintered under the stages of the stove are commencing to grow, and must be potted before the shoots grow too long. Shake the old soil from them, and if there is any sign of decay scrape the affected part and cover with powdered charcoal. Pot the plants in a compost of good loam, leaf-mould, a little peat, dried cow manure, silver sand, and charcoal. Do not pot too firmly as anything that promotes stagnant soil is very harmful. Place the pots in an atmospheric temperature of 70 degs. and give but little water until growth is well advanced. Any repotting must be undertaken before the plants have become in the least pot-bound.

Freesias which have passed out of flower should be afforded generous treatment. Manure-water may be applied to the roots up to the time when the leaves turn yellow. On the first appearance of the yellowing of the leaves the water supply should be lessened, continuing the decrease until water can be safely withheld. The plants should be exposed to full sunshine in order that the bulbs may thoroughly ripen.

Calceolaria alexicaulis.—Plants that were lifted from the cutting beds for providing standards will now be potted on into 7-inch pots. The same applies to *Heliotropes* and other standard plants intended for planting out in summer.

French Beans.—There is now little difficulty in getting a plentiful supply of this favourite vegetable. Plants which are fruiting are afforded copious supplies of liquid manure and occasional applications of Clay's Fertiliser. A moist atmosphere is maintained and the foliage thoroughly drenched twice daily with tepid water. From now onwards it will not be necessary to employ strong fire-heat; an atmospheric temperature ranging from 55 degs. to 65 degs. will be ample. To maintain a continuous supply seeds are sown at intervals of a fortnight. At this season I prefer to sow Canadian Wonder, its vigorous constitution ensuring success under forcing conditions.

Potatoes in pits.—The earliest plants now need earthing up. This is done by placing some old potting soil amongst the plants. Previous to earthing up, the bed is carefully watered with clear, tepid water. Air is admitted freely to this crop during mild weather. Further plantations will be made under glass to maintain a

training of the shoots, and over-cropping must be avoided whilst the plants are young. A surface dressing of good loam and spent Mushroom manure in equal parts, to which has been added a little fertiliser, will be applied frequently in small quantities. A brisk heat and moist atmosphere are maintained, damping the paths with manure-water early in the afternoon. Seed for a successional crop has been sown singly in small pots.

Vegetable Marrows.—Where portable frames are available for the purpose good crops of Vegetable Marrows may be obtained from the middle of April onwards. Seeds should be sown singly in 60-size pots and germinated in gentle warmth. Endeavour to forward the plants by planting them under portable frames on mild hot-beds. When safe to do so the frames can be removed and the plants top-dressed. They will then continue to furnish fruits until frost destroys them in the autumn. F. W. GALLOP.

Early-flowering Tulips in a pot.

supply until tubers can be obtained from the open air. Tubers for planting should not be allowed to remain longer together in large quantities, or they will make spindly shoots, and their value for planting will deteriorate. They should be laid out singly in a well-ventilated shed, where protection from frost can be given if necessary.

Carrots sown in frames in January are ready for thinning. The plants are thinned to 4 inches apart, and afterwards the soil is watered to settle it about the roots. Soot is an excellent fertiliser for Carrots, and this should be dusted about the plants occasionally. Plenty of fresh air should be admitted on all favourable occasions to prevent the plants becoming drawn. Another sowing will now be made in a cold frame to furnish roots for a succession.

Cucumbers.—Plants put out on well-prepared beds last month are now coming into bearing. They require constant attention as regards the stopping and

SCOTLAND.

Sweet Peas.—During the week a considerable quantity of Sweet Peas has been sown in pots. The practice followed is to put about a dozen seeds in a pot 5 inches in diameter, the seedlings when planted out making nice clumps. A rather holding loam is preferred for sowing, with only sufficient sand to make the whole porous. In order to prevent mishaps from vermin, the seeds, previous to sowing, were damped and rubbed over with red lead. The pots are placed in an unheated house and will be very sparingly watered until germination takes place. The pots used are made of cardboard. These answer the purpose very well, are very light, and if carefully dried and stored after use they remain serviceable for a number of seasons.

Stove plants.—Having, meantime, completed the work of putting in cuttings of greenhouse subjects a beginning has been made with the propagation of such stove plants as may be in demand during the season, and with the repotting of such

things as require attention in that respect. Many stove plants are more effective in a young state, so that as soon as sufficient cuttings are secured the old pieces are discarded. Such plants include *Pentas rosea*, *Justicia carnea*, *Panax Victoria*, *Ruellia Portella*, and similar things which can be grown to a good size in the course of a season. These young pieces, too, always produce blooms of a superior quality, and are much more useful for general purposes than older and larger specimens. A further batch of cuttings of *Lorraine Begonias* was got in—chiefly leaf-cuttings, although a few strong basal shoots were also made use of. A quantity of rooted cuttings of *Begonia Rex* was potted off into 3-inch pots. These showy things have been rather neglected for some years. Young plants of *Dieffenbachia Bausei* have gone into 4-inch pots. These are useful by way of variety. *Saintpaulia ionantha* is easily increased from leaf-cuttings. Either grouped or as dot plants its Violet-like blooms are attractive. Cuttings of *Acalypha musaica* and *A. hispida* are being put in as they become available. These are useful either as small plants or when grown on till they occupy 8-inch pots. Trailing plants for draping are readily increased, and, among others, cuttings of *Panicum variegatum*, the *Fittonias*, and *Tradescantias* were put in in quantity. A very useful plant is *Eulalia japonica variegata*, old plants of which were broken up and repotted. *Bryophyllums*, including *B. crenatum* and *B. calycinum*, were put into 3-inch pots. The former is rather straggling in habit and requires pinching at intervals to induce a neat plant, and, further to assist in this respect, two plants are grown in each pot.

Coleuses.—In the course of the week some more young plants of brightly-coloured Coleuses were moved from 4-inch to 7-inch pots. These will, by and bye, receive a final shift into 9-inch pots, although I think that Coleuses always colour better when rather restricted as to root-run and given plenty of heat, light, and water. Nevertheless, a few large plants are always handy, and if used for housework their loss is not great, and they are easily replaced. A further lot of cuttings was put in.

Myrsiphyllum asparagoides.—One of the most attractive plants in the greenhouse just at this time is this. It has run freely up wires and has reached the top of the structure. Apart from its attraction and glossy green leaves the trails are covered from top to bottom with the minute blooms, which have a further merit by reason of their delicate Lily-like perfume. This variety reproduces itself freely each year by means of self-sown seeds, large quantities of young plants being found under the stages in its immediate neighbourhood. This, I find, succeeds better when treated as an annual.

Eucalypti.—After having given up the culture of the *Eucalypti* for a number of years, seeds of *Eucalyptus globulus* and *E. citriodora* have been sown. Both of these varieties at one time succeeded fairly well out of doors, *E. globulus*, especially, lasting for a number of years until killed by a severe frost. *E. citriodora* is more delicate, and while it does fairly well in the open it is always safer to lift it on the approach of winter and remove it to a frost-proof house or pit. This variety, as its name indicates, is more delicately perfumed than the more usually grown *E. globulus*, its odour resembling to some extent that of the well-known *Aloysia*.

Gerbera Jamesoni.—Seeds of this have been sown in heat. The seedlings will be grown on rather quickly in order that they may be of some size when planted out. If

space can be afforded, a few plants may be grown in pots, as the flowers are much brighter under glass.

Primula obconica and **P. verticillata** were also sown during the week. The latter is not greatly, if at all, inferior to **P. Kewensis**, and is, or so I think, hardier and less liable to collapse so suddenly as **P. Kewensis** occasionally does. There is, in the case of **P. obconica**, always the prejudice against its employment to be contended with. The variety, however, is so valuable, and so greatly improved now, that it is worth taking a little risk. From long and close observation I feel certain that many people are quite immune from its irritating effects. I can handle it with impunity, and therefore always look after the plants, although, on the other hand, **Humea elegans** produces in me the same irritation which **P. obconica** does in others.

Hardy Chrysanthemums.—Cuttings of the best type are now available, and a quantity was got in during the week. These, dibbled in thickly into sandy soil and kept airtight, soon root. Further batches will be put in from time to time until the needful number is secured. Shading is necessary in the event of bright sunshine.

Horse Radish.—This is a very good time at which to make fresh plantations of Horse Radish. A deep, mellow part of the garden is advised for this crop. Select fairly strong and straight thongs, and make a deep hole with a crowbar. Drop in the thongs, and work in an allowance of sand round them. I have found sea-sand suitable for this.

Rhubarb.—Now that the crowns are beginning to show signs of renewed growth; should any replanting or division be needful, the work can safely be done. To plant Rhubarb when in a dormant state is to court failure, for it will be found that a large proportion of the roots will rot, more especially should wet weather ensue. The ground for new plantations ought to have been well, but not recently, manured. Many seem to think that Rhubarb ought to succeed in any out-of-the-way corner, but this is a mistake, for, like all other things, it must receive attention and have as good an exposure as possible.

Work and weather.—Work has again been interfered with by rain. The outlook begins to be a little serious, and conditions are sufficiently depressing. During the past week it has only been possible to go upon the soil for one full day, and while arrears are not, so far, very alarming, yet the season is advancing and work increases from week to week. It is better to defer operations until the soil is workable, although at times one gets impatient.

W. McGUFFOG.

Balmac Gardens, Kirkcudbright.

OBITUARY.

CANON ELLACOMBE.

THE dean of British amateur gardeners is no more. He died at ninety-four years of age, full of interest and active to the last. Tall, athletic, and healthy, he was as ready for a mountain in Britain or the Alps as for his garden, which was extremely interesting and full of delightful and often rare plants. He followed his father in the same pursuit, so that it cannot be said that he made the garden; but he added much to it, and the collection of plants was one of the best. For sixty-five years rector of Bitton, in Gloucestershire, he kept the lamp of true gardening alive in the early Victorian days, when men went crazy to make their gardens like carpets, and jolly bad carpets. His books were excellent, especially those on Shakespeare's flowers.

CORRESPONDENCE.

Questions.—*Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly written on one side of the paper only, and addressed to the EDITOR of GARDENING, 63, Lincoln's Inn Fields, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, the name and address being added to each. As GARDENING has to be sent to press some days in advance of date, queries cannot always be replied to in the issue immediately following their receipt. We do not reply to queries by post.*

Naming plants.—*All who wish their plants to be rightly named should send fair examples of each—the stem, leaf, flower, or fruit. (Snippets of leaves and points of shoots are useless.) Not more than four plants should be sent in any one week by the same correspondent. Where more than one kind is sent they should be numbered. Of conifers the fruit should always be sent.*

Naming fruit.—*Several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. We can undertake to name only four varieties at a time.*

PLANTS AND FLOWERS.

Camellia dropping its buds (D. T.).—The reason of your Camellias dropping their buds is probably owing to their having been kept too dry at the roots. This would also tend to cause the leaves to assume a yellow tint, but the latter is often brought about by over-watering, and as you give no hints as to the state of the soil, we are unable to say in which particular you have erred. At all events, the roots are not in a healthy condition, or the plants would not be in the unsatisfactory state they now are. The soil should be kept moist, but should never be allowed to become sodden. There was no sign of any insect or fungoid pest on the leaves you enclosed.

Fuchsias in greenhouse (F.).—We do not recommend Cocanut-fibre refuse for your slate staging, as the continual moisture from the plants causes it to become putrid quickly, and it is not beneficial to plants of the kind you mention. But if you require a moist bottom, we recommend you to use 2 inches or 3 inches of ashes, small coke, or shingle. Either of these will suffice and be more advantageous for your plants. Wood-lath staging is not beneficial to plants. We prefer slate staging, as it lasts longer, and can be used for both purposes with or without a covering of some material. You will do well to use one of the materials advised.

Indiarubber-plant failing (Miss Hulke).—It is quite impossible to determine the cause of the Indiarubber-plant falling into ill-health by the examination of a diseased leaf. From your note, however, we should say that the roots have fallen into a bad state, probably owing to dryness or having been over-watered. When an old plant such as yours is falls into ill-health, it is much more difficult to revive than in the case of a young one. The only thing you can do is to turn it out of the pot and ascertain the condition of the roots; then, if they are in a bad state, all decayed portions must be cut away, and the plant repotted. For this purpose it is very essential that the pot be quite clean, and effectually drained. A suitable compost may be formed of one part each of loam and leaf-mould, or peat, with nearly half a part of silver sand. After repotting, the plant should be put into a warm-house—that is to say, where the temperature ranges from 60 degs. to 70 degs., and, if possible, a little bottom-heat should be given it. Watering must be very carefully done till the roots resume their normal activity. If, on turning the plant out of its pot, you find the roots in good condition, we can only suggest that the plant may be suffering from exposure to cold draughts.

Thunbergia laurifolia (D. Stuart).—The specimen sent was so much shrivelled up and quite brown that it was impossible to even make out the colour of the flower. However, if it is of a rather light blue, we have no hesitation in saying that it is *Thunbergia laurifolia*, a common climbing plant in India, whence it was introduced in 1856. It is a very desirable climber for the roof of a stove, where it will grow and flower freely. Cuttings of the half-ripened shoots will root without difficulty if taken in the spring as soon as they are available and dibbled into pots filled with a mixture of loam, peat, and silver sand in equal parts. They must then be

put into a close propagating case in the stove, under which conditions roots will soon be produced. After this they should be hardened off to the ordinary atmosphere of the stove and then potted singly. For this a compost made up of equal parts of loam and peat or leaf-mould, with a good sprinkling of silver sand, will suit them well. In potting off the rooted cuttings the soil should not be sifted. If put into larger pots when necessary, the young plants will make rapid progress. Red-spider is sometimes liable to attack the leaves, especially if the atmosphere is dry, but it can be kept down by a liberal use of the syringe. Beside the specific name of *laurifolia*, this *Thunbergia* is sometimes known as *T. Harrisii*.

FRUIT.

Grafting Oranges (L. M. Urbridge).—Grafting is a difficult operation, and is usually done in the early spring by cutting seedlings down hard, then getting small pieces of firm wood and working them on to the stocks, sealing over the wounds with wax. The work should be done in heat and in a close frame.

The Loganberry (Miss Lee Norman).—The Loganberry should be treated in the same way as the Raspberry—that is, the old fruiting wood should be cut out each year to allow room for the new growths, which in the winter should be shortened back to the length of the stakes. These stakes should be not less than 8 feet high, and fixed on each side and in the centre of the plant, or the plants may be set out against a warm fence or wires stretched along the row in place of stakes. The best way to grow the Loganberry is on wires in a similar way to that employed for growing Raspberries, only more height must be allowed—say not less than 6 feet. A good mulch of manure and plenty of water, if the season is dry, must be given when the fruits are swelling.

VEGETABLES.

Parsley (Vegetable Grower).—The constant demand for this is liable at times to exceed the supply, and unless special means have been taken to bring some on under glass in readiness for February and March, a dearth is more liable to come in those months than any other time. Big sowings made during the previous year are not always to be depended on, for the autumn growth is liable in some seasons to go off wholesale and be unfit for garnishing. Plant a frame in autumn with thinnings from the main crop, which have by that time got rather large, but which transplant readily and grow into good plants by winter. Nothing is more satisfactory in a scarce time or when the ground outside is covered with a deep coating of snow than to have such plants from which to gather as required. If, however, this has not been done and there is any danger of a break in the supply, plants lifted now and put into boxes or pots will soon come into growth again if they are placed in a gentle growing temperature, but no attempt must be made to unduly force them into growth or the leaves will become flabby and useless.

SHORT REPLIES.

E. D. Daniel.—Bonne de Malines Pear is the same as Winter Nelis. The other Pears may be obtained from Mons. F. Jamin, Grande Rue, à Bourg la Reine (Seine), France.—**J. Subsciber.**—We do not know a book on the subject at the price you mention. "The English Flower Garden," price 15s. 6d., post free, from J. Murray, Albemarle-street, London, W., should, we think, be very helpful to you.—**W. F.** We have never heard of a double form of *Pyrethrum uliginosum*.

NAMES OF PLANTS AND FRUITS.

Names of plants.—**E. Murphy.**—Ferns: 1, *Pteris serrulata*; 2, *Pteris serrulata cristata*; 3, *Pteris scaberula*, but specimen too poor to name with any certainty; 4, *Pteris cretica*.—**C. S.**—*Rhododendron Nobleanum*. See note on page 114.—**M. C. Sturge.**—*Garrya elliptica*.—**J.**—1, *Berberis Aquifolium*; 2, *Cotoneaster microphylla*; 3, *Cydonia japonica*; 4, *Daphne Laureola*.—**R. P.**—1, *Garrya elliptica*; 2, *Cornus mas*; 3, *Forsythia suspensa*; 4, *Lonicera aruco-reticulata*.—**Y. R.**—1, *Phlebodium aureum*; 2, A form of *Helleborus orientalis*.—**X. Z.**—1, *Clivia miniata*; 2, *Acacia dealbata*; 3, *Begonia metallica*; 4, *Habrothamnus elegans*.—**C. S. M.**—1, *Pteris tremula*; 2, *Pteris serrulata*; 3, *Pteris cretica albo-lineata*.
Names of fruits.—**Snapper.**—Apple: Fearn's Pippin. It may be that the tree is too vigorous. If so, root-pruning would do good.—**J. R.**—Apples: 1, Annie Elizabeth; 2, Bramley's; 3, Northern Greening; 4, French Crab.—**H. H.**—Apples: 1, Rymer; 2, Norfolk Beaufin.—**E. C.**—Pears: 1, Winter Nelis; 2, Nouvelle Fulvie; 3, Verulam (stewing only); 4, Josephine de Malines.

NOTES OF THE WEEK.

The Shamrock Pea (*Parochetus communis*) which was placed in a box in cold frame last October is now (middle of February) flowering freely. As far as I remember, even in a warm greenhouse *Parochetus* seldom flowers really well till March or April.—E. CHARLES BUXTON.

Andromeda japonica.—A rich bunch of this, one of the best flowering evergreens from Japan, comes from Knaphill. It is well known now, but not always well grown. The Knaphill soil suits it well. I grow it in quite different soil—cold loam on sandstone rock, with some additions of leaves and sand—and it puts up with the treatment. Being one of the shrubs one cannot do without, each must do the best he can with his soil.—W.

Fasciation in Snowdrops.—The present season has been remarkable for examples of fasciation among the Snowdrops. While picking some of these flowers recently, in a short time no fewer than eight of these freaks were observed. This is something new in my experience of Snowdrops, for in previous years, although occasional fasciated stems have been noticed, yet they were not so common as is the case in the present spring.—W. McG.

Winter Heliotrope.—"W. McG." must be hard up if he has not a bank of ashes, sand, or gravel to put his Winter Heliotrope on. I had the plant for years alongside a grove in ordinary soil not too rich, but it rarely flowered. Then, piled round a reservoir, there was a bank of sand on which nothing would grow, and I took the Winter Heliotrope there. It grows there very well and flowers in quantity, and is very welcome in winter.—W.

Gardening in the parks.—We see in the papers that much of the "floral display" in the London parks is to be reduced this year. This is a good thing, too, as it is so often over-done, and too thickly set on the ground for any relief or artistic effect. Perhaps the most outrageous example of it is that in front of Buckingham Palace, which is every year a nursery garden of scarlet Pelargoniums. It was a bad idea to put a garden there at all. Stately trees and simple Grass were all that was wanted there.

Raoulia australis.—This is one of the neatest and dwarfest of the silvery carpets which can be considered hardy in this country. It is a close-growing plant,

barely rising above the soil, and hard to the touch. It looks as if it could be deepened upon as both frost and rain proof when in a dry place with plenty of drainage. I grow it in a sunny moraine, and it stands well without protection, although this winter has not been an ideal one for plants of its character. It comes from New Zealand and bears small white flowers.—S. ARNOTT.

Blue-eyed Mary (*Omphalodes verna*).—I know no plant flowering at the present time which produces such handsome deep blue flowers as this. No prettier or more satisfactory plant exists for naturalising than this, which with me has formed little colonies in all sorts of positions.—E. M.

Wallflower Harpur Crewe.—Mr. Clarence Elliott sends us flowers of this uncommon little double Wallflower. In some districts near the sea in England and Ireland one may see very pretty examples of double Wallflowers, but the plant is not really hardy, and, therefore, it dies in valleys in inland districts; and in the Home counties it is unusual to see it at all. This kind forms neat little bushes.

Big trees down and no hearths for wood fires.—People tell us of an immense destruction of trees in some places, and no one has a proper hearth for burning the wood, although little else can be done with the branches. A big mistake in country places was getting rid of the old hall fireplace. It is the cheapness and facility of coal that led to the use of this dirtiest of fuels. Every country house where there is wood should have a good wide down hearth in the hall, and also in the workmen's mess-room.—W.

Gardens and water-colours.—I went to see a neighbour's garden the other day. The owner is a student of water-colour painting, and he bases his ideas of gardening on things that would look well in a drawing. Presently we came to the end of a walk where there was a ring of variegated Lawson Cypress, and he said it put a pretty touch of colour. We passed next a lumpy Thuja in shape like a fallen-down pudding, and seeing that I looked rather doubtfully at this he asked what I thought of it. I said that if it were mine it would be put on the fire-heap the next morning. Next we came to a Cypress, one of those folded umbrella-like forms of it, which, when old, falls to pieces and is always ugly, and I ventured to air my views of such malformations. But he said it gave a charming effect, and used some term in water-colour work to

justify his taste. All his Conifers were spread about in the usual stupid crinoline fashion, and showed little sign of the stem, the chief glory of the Pine. Gardening in a picturesque country such as this was may be a much bigger thing than may be learnt from water-colours.—W.

Iris reticulata.—The first bloom of this handsome Iris was noticed on February 12th, fully expanded and clean. Formerly *I. reticulata* was grown in a hardy-plant border, but more success seems to follow when the bulbs are planted at the foot of a south wall, protected by a coping of glass about 2 feet wide. In a similar position *I. stylosa* is blooming very freely. I notice that some writers prefer the more unwieldy name of *I. unguicularis* in referring to this Iris.—KIRK.

Ficaria grandiflora (The Great Pilewort).—I like this Buttercup-like flower, which, coming with the Snowdrops and Violets, should be grown by all who can give up a corner to a few plants. In some respects it reminds one of the Kingcups, with its large shining leaves each 3½ inches across and yellow flowers each 2 inches across and borne on erect, stout stems 10 inches or more in length. These stems usually carry a leaf about half-way down like the Kingcup. I have it in a wet, sticky soil, and it seems quite at home.—M.

Early-flowering rock plants.—Your readers may be interested to know that the following alpine and rock garden shrubs are now in bloom in this district:—*Saxifraga Burseriana* Gloria, *S. B. multiflora*, *S. Haagi*, *S. Apple Blossom*, *S. Cherry Trees*, *S. Boryi*, *S. Frederici Augusti*, *S. apiculata*, *S. Elizabetha*, *S. Salomoni*, *S. sancta speciosa*, *Primula amœna*, *P. denticulata*, *P. Lilac Queen*, *Anemone Hepatica rubra*, *Arabis alba*, *Tufted Pansies*, *Erica carnea alba*, and *Rhododendron præcox*. Usually these do not come into bloom for many weeks yet, owing to the exposed nature of their sites, their earliness this season no doubt being due to the extreme mildness of the winter.—E. T. ELLIS, *Weetwood, Ecclesall, Sheffield*.

The Cornelian Cherry (*Cornus mas*).—This is now (February 14th) blooming freely, the leafless branches almost hidden by the clusters of bright yellow flowers. With the advent of the Japanese Witch Hazels this fine old *Cornus* seems to have been neglected. It will thrive almost anywhere and in any soil, and flowers in quite a small state. The specimens referred to as in bloom are nearly 20 feet in height

and with a good spread. The flowering sprays are very welcome in the house, where they last a long time, especially if cut in the bud. Like all trees and shrubs which bloom in a leafless state, this should be planted in front of larger evergreens and where the sunshine can play freely among its branches. The flavour of the fruit, which resembles a small Plum, is sharp, but not unpleasant. The Turks still use it in the manufacture of sherbet, and the bark furnishes the red dye for their fez.—E. MARKHAM.

The common Polypody (*Polypodium vulgare*).—It is a pity this fine Fern is not more grown, for there are few dwarf evergreen plants capable of producing such a deep green carpet during the winter. Perhaps, like many other of our good native plants, it has been pushed aside to make room for some less valuable kinds. Although a charming plant in summer, it is in the dead of winter that it is seen at its best. With me it is growing on a border 3 feet wide and 5 yards long at the base of a high wall, the whole shaded by the large boughs of a Yew-tree, which limit its water supply to a considerable extent. In this position it seems perfectly happy, and has become one dense carpet of fronds, through which Daffodils will shortly appear. This Fern is a splendid plant for the wild garden. Grouping on the shady side of the rock garden, intermixed with Fritillary or the Summer Snowflake, is a charming way of using it, while as a foreground and carpet to slender-growing shrubs it would answer. A slight shade it apparently enjoys, as in its native haunts it is usually found beneath some tree or low-growing bush.—E. M.

Hamamelis arborea.—In reply to "W. T." (page 81) *re* the above, he will find in "Flora and Sylva," Vol. 2, page 89, this charming Witch Hazel described as the earliest to flower, the largest and best of the group, etc. If "W. T.," who says that this variety is, in a general way, later than *H. mollis*, which is sometimes in flower by Christmas, will refer to the list of plants in bloom (December 30th) he will find *H. arborea* is included. What is "W. T.'s" opinion as to the dimensions of *H. mollis* as compared to those of *H. arborea* when the two attain age? In a young state the difference between them is not so great as many are led to believe, the chief distinction being that *H. mollis* has larger leaves and brighter flowers than those of *H. arborea*. The fact that *H. mollis* in the Coombe Wood Nursery was for twenty years merely looked upon as a rather larger form of *H. japonica* speaks for itself. In support of his criticism of my note "W. T." quotes a well-known author, but mistakes are at times made by the best of authorities, and with at least one member of this genus I find myself at variance with the author referred to, who describes *H. virginiana* as follows:—"The effectiveness of this Witch Hazel is spoilt by its being in full leaf at flowering time, so that the blossoms, closely tucked to the twigs, have little chance to show themselves, etc." In early October of the past year there was no more beautiful object than this Witch Hazel, large specimens from 10 feet to 12 feet high and as far through were bedecked with blossoms, the leaves turning from green to rich golden-yellow. The flowers were easily distinguished. Their value in a cut state when placed where the sun can reach them in the room is considerable. It may be that such beauty is only met with on specimens of considerable age, but I think it worthy of notice, as it may encourage the further planting of this old American species.—E. M. *Sussex.*

FRUIT.

SOME DELUSIONS ABOUT PRUNING.

THE other day I went to see a neighbour's garden, and there found some promising young Pear-trees, pyramids mostly, with all the main shoots cut off, as one might cut sticks in a copse for hedge stakes. The pruner told me his object was to make the tree form spurs. I ventured to tell him that that was the best way to prevent them forming spurs, and that the great thick shoots cut would start up again in the form of watery shoots. I told him that the main function of those branches was to bring the sap up to the young buds. What teaching had led to the trees being mutilated in that way I do not know, but a more fatuous plan could hardly be followed. He told me he was sorry he had only time to root-prune a few of the trees, and I told him he was a lucky fellow on that account. His soil is like mine—a cool, poor loam on a sandstone bottom. I said if he had been to see my trees in the autumn he would find them not cut back, but the shoots bearing a good crop of handsome fruit.

This fashion of over-pruning has gone on for years in gardens and has done infinite harm. It begins with young trees fresh from the nurseries, which some books teach should be cut back. That practice I believe to be wrong. Healthy fruit-buds are not produced on that system.

Nothing is to be said against wise pruning. Without it we cannot hope for good fruit, but hacking all the main uprising shoots of a tree back to induce fruit-spurs is a very different thing. W.

GARDEN SOURCES OF POTASH.

EVERY garden contains sources of potash of its own. For the past ten years I have grown crops in abundance by simply utilising the home garden supplies of potash. This element may be derived from many waste products of the orchard and garden in sufficient quantities to supply the requirements of growing crops. There are natural supplies of mineral salts in all arable soils. Some of these soils contain more potash salts than others. Muck, peat, gravelly and sandy soils are very deficient of potash, but clay loams usually contain sufficient unused potash salts for good gardening. These mineral substances are the natural supplies of potash in soils. Where cultivation has been carried on for years, the potash in surface soils has been largely consumed by growing crops. Unless potash in some form is annually supplied to meet the drain made by crops, soils decrease in fertility and crop production becomes more and more difficult. But subsoils of clay loams and other soils rich in mineral salts contain large quantities of potash, though not in readily available form. All organic matter contains a certain quantity of potash. Beet and Mangold leaves contain a high percentage of potash. When these waste products are turned under, their decay not only liberates their contained potash as food for subsequent crops, but they also increase the solubility of potash minerals in soils. Deep cultivation and organic manures will supply our gardens with a supply of potash that might otherwise be useless.

The chief sources of potash supply around orchards and gardens are many substances usually allowed to go to waste entirely, such as dried weeds, hedge trimmings, prunings from fruit trees and bushes, shade-tree cuttings, Corn-cobs, and other waste materials found around every garden. The best way to secure the con-

tained potash in these materials is by burning. The resulting ashes contain large quantities of potash in readily available form. The amount of potash varies with the material burned. Commercial kainit contains only 12 per cent. of potash in the form of potassium oxide. This is not nearly so available to plants as the potash in ashes of garden waste products. These different forms of organic ashes contain potassium carbonate, one of the most readily soluble potash salts.

For this reason care must be used in handling the ashes of garden wastes. If rain or dew falls on them they may lose half their fertilising value in a single night. This would not make so much difference if the materials are burned in places where the fertiliser is desired, as the rain would carry the dissolved potash into the soil, where it becomes fixed either by soil micro-organisms or by organic substances. But if these ashes are required on some other part of the garden, or at some other season of the year than when produced, they should be gathered as soon as cool enough and kept dry. They may be preserved for a considerable time without loss of fertilising value if they are thoroughly mixed with superphosphate and kept in a dry place. A small quantity of this mixture placed around flowers and vegetables will result in increased growth and vigour.

As previously stated, easily soluble potash salts like potassium carbonate do not readily wash out from the soil, because they become fixed by micro-organisms and decaying organic matter. Wherever good gardening is practised by using sufficient organic ashes and manures, and by deep tillage to bring up the subsoil occasionally, the quantity of potash in garden soils may be increased rather than diminished by cropping, because more potash is supplied by these means than is removed by the crops. This is one of the best ways to conserve soil fertility. Both are good garden practices.—J. B. MORMAN, *Kensington, Md., in Garden Magazine.*

PLANTING STRAWBERRIES IN SPRING.

EXPERIENCED growers plant, when practicable, in autumn, so that the plants get well hold of the ground by winter and are established when the growing time returns. Those who have not been able to do this may, however, plant in spring with every prospect of success. Growing Strawberries in frames for the London markets I require every year several thousands of good young plants which are lifted and planted in late autumn. I try to get the runners put out on ground that has been cropped with Potatoes and which requires no preparation, being sweet and clean. It frequently happens, however, that I cannot get them all planted at that time, and some have to be done in spring. This, of course, involves extra labour, as the ground has to be dug up rough in February or early in March and allowed to sweeten. I certainly prefer autumn planting, but frequently something occurs that prevents my getting them all out at that time, in which case I plant in March and find that they do nearly, if not quite, as well; in fact, it has occurred, after a very inclement, changeable winter, when there was much frost, that the spring-planted ones turned out best. Several times I have planted early in April and have had good results. When this has been the case and the weather has been dry I have made a practice of "puddling" them in, that is, treading the soil firmly round the crowns to form a basin, filling up

with water, and when this soaks away levelling with loose soil, which, when dry, acts as a mulch. It is a great help to the plants if manure-water is used, as this gives them an early and more vigorous start. A strong growth will be assured if, before the lumps are broken and the ground levelled, a moderate dressing of rotten manure, which in the process of breaking down the ground becomes thoroughly incorporated with the soil, is given. If puddled in there will be no need for watering for a month, even should the weather keep dry. Later on in a time of heat and drought an occasional moistening may be necessary. A great thing with new Strawberry plantations is to get the hoe well at work early in the season, not waiting for weeds to come, but well stirring the surface so that it becomes fine to a depth of 2 inches, which acts as a mulch, thus checking evaporation and allowing the free admission of rain and the heavy dews which we frequently get in the months of July and August. I am behind this year. I could not do any planting last autumn and have, therefore, all to do in March and early in April. I do not trouble, however, if I can

TREES AND SHRUBS.

RIBES LAURIFOLIUM.

This is an interesting but not very showy species of Ribes, native of Western China, whence it was introduced in 1908. It is an evergreen, growing 4 feet or more in height. The flowers are borne as early as February, male and female blossoms being produced on separate plants. They are in racemes each 2 inches to 3 inches long, and greenish-yellow in colour. As a rule, the clusters of female flowers are longer than those of male plants. It should be given a sheltered position, and, except in the warmer counties, may require wall protection. Any good garden soil suits it, and it can be increased by seeds or layers. The accompanying illustration is of a shoot of the male-flowered form. D.

EARLY FORSYTHIAS.

THE mild weather throughout January has resulted in many plants commencing to grow and flower well in advance of their normal time, the Forsythias being a case in point. During the last week in January

will be cut away. Quite different in habit from *F. suspensa* is

F. VIRIDISSIMA, another Chinese shrub introduced about 1841. It is often met with from 5 feet to 6 feet high, whilst the other species exceeds 12 feet in height. It is of stiff habit with erect, green branches clothed with deep green leaves, and blooms freely, the flowers normally being borne about a fortnight later than those of *F. suspensa*. For planting in groups in the open or in the shrubbery it is very useful. Between these two species there is a very useful hybrid,

F. INTERMEDIA, which is very well named, for it is distinctly intermediate in habit. It is a very vigorous shrub growing 10 feet or 12 feet high with a wide spread, its golden bell-like flowers being borne freely a little later than those of *F. suspensa*. Two exceptionally free-flowering forms have been given varietal names. They are *densiflora* and *spectabilis*, and people would do well to plant them in preference to the type. Another variety, *vitellina*, is also distinct by reason of its darker-coloured flowers. A third species of Forsythia is the Albanian

F. EUROPEA, an erect, sparsely-branched shrub with the familiar golden bell-like flowers of the other Forsythias, but much less effective and not worth growing except in gardens where full collections are desired. It was introduced in 1899, but is not widely known.

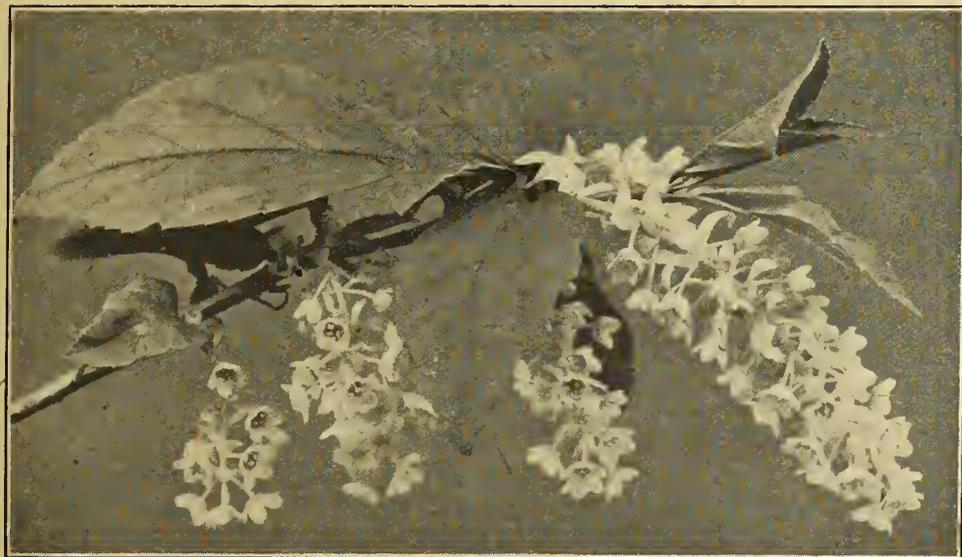

The Forsythias are easily increased by cuttings of the soft shoots in June, cuttings at that time rooting more quickly and forming better plants than cuttings of partly or fully ripened wood at later dates. They thrive in any good garden soil. All may be used for forcing, but *F. suspensa* is superior to the others. The shoots are also very useful for cutting for indoor decoration. D.

APRICOTS, CHERRIES, AND PEACHES IN CHINA AND JAPAN.

IN China and Japan, except the colder parts, the first flowers to open on deciduous trees are those of the Ume (*Prunus Mume*), generally known as the Japanese Apricot, and those familiar with the porcelains of the Far East will appreciate it as the Plum-blossom so often employed in design. This plant is wild

in central and western China, but it has been cultivated in all but the colder parts of that land from time immemorial and was from China introduced to Japan by Buddhist priests more than one thousand years ago. In both China and Japan it is much grown in pots as a dwarfed bush, and in this condition flowers profusely. Cut branches with flowers are abundantly used for house decoration—so much so, in fact, that it is safe to say that in season where it is grown in China and Japan no temple, shrine, or dwelling, be it castle, palace, or peasant's hut, is without its sprig of Ume.

THE COMMON PEACH (*Prunus persica*).—Cultivated in the gardens of China and Japan is a number of varieties with large and double flowers, in white, pink, rose-red, and bizarre, and strikingly handsome. In addition to the common Peach two other species grow wild in China. One of these, *P. Davidiana*, is confined to the northern parts of that country, and in the Arnold Arboretum it is the first of its class to blossom. Often the flowers get damaged by frosts in the changeable climate of New England. The tree is of slender growth with thin ascending-spreading branches, and there are two forms, one with white and

A flowering shoot of Ribes laurifolium, showing the male blooms.

get the ground dug up roughly early in March. It quickly dries and sweetens at that time. An important point is not to allow the roots to dry in transplanting, as this will cause a check, which at that late season it is necessary to avoid.

J. CORNHILL.

Nuts.—As the female blossoms are now plainly discernible a commencement with the pruning of the bushes has been made. The female blossoms are not very abundant, neither have male catkins been very plentiful either on Cobnuts, Filberts, or the common Wood Nut. Still, as is often the case with the Nut crop, it may eventually prove to be a much better one than present signs lead one to anticipate. —A. W.

American blight.—A correspondent lately called attention to the necessity of adopting drastic measures in connection with American blight, and it is a question if anyone allowing trees to get into a bad state should not be compelled to remove them. I remember in the late seventies a market garden with a lot of young standard Apples that were literally smothered with the pest. This garden adjoined a fruit-tree nursery, with the result that for several years nearly every Apple-tree, and also some of the Pears, were more or less affected, a state of things very bad for the purchaser, especially if this happened to be unnoticed at planting-time and the insect had the opportunity of making headway.—E. B. S.

numerous flowers were open on *F. suspensa*, and now (early February) some plants are as forward as is often the case in mid-March.

F. SUSPensa is a very accommodating shrub, for it thrives under a great variety of conditions and is equally beautiful whether against a fence or trellis, as a bush in the shrubbery, as a group in the wilder parts of the garden, or on the lawn. Moreover, it may be left unpruned year after year, or the branches may be cut back annually as soon as the flowers fade. Plants grown against fences, trellises, or walls are improved by an annual pruning, for they are thereby kept within bounds and continually furnished with young wood on which the best flowers are borne. In plants grown in the open, if pruned once a year, the habit is considerably altered, for, instead of long, slender branchlets being formed, they often produce strong, erect shoots $3\frac{1}{2}$ feet to $4\frac{1}{2}$ feet long which bloom from end to end. Certain plants are more pendent than others, and those exhibiting the stiffest habit are best as specimens. Pruning must, however, be done as soon as the flowers fade, for if it is done after young wood has been formed the flowers for the following year

another with pink blossoms. The other species (*P. mira*) is a new discovery which I made in 1910, in the Chino-Thibetan borderland. The flowers are unknown to me, but probably resemble those of the common Peach. This new species is remarkable in having a very small, flattened-oval, and perfectly smooth stone; its value, if any, as a new fruit-tree has yet to be made known, but for the hybridist it certainly has attractions.

THE COMMON APRICOT (*Prunus Armeniaca*), its specific name notwithstanding, is also native of northern China and, like its allies, is not only a valuable fruit-tree, but is likewise a handsome and ornamental flowering plant. This, too, has been long cultivated in the Far East, and in Japan varieties differing in habit and colour of flowers have originated.

In Mandschuria a third species of Apricot (*P. mandshurica*) grows wild. This tree is distinct, with its light grey rather scaly bark, wide-spreading crown, and spiny inner branches. The flowers are large, white or nearly so.—E. H. WILSON in *Garden Magazine*.

NOTES AND REPLIES.

Rooting Daphne Mezereum, etc.—Please let me know whether I am likely to be successful at the present time in rooting cuttings of *Daphne Mezereum*, *D. M. alba*, and *Ceanothus Gloire de Versailles*, which have just been given me. I have them in pots of sandy soil in a box with glass lid, standing on stage of cold greenhouse.—MARGARET.

[We do not think that you are likely to meet with any success in striking the cuttings under the conditions named. The usual mode of increasing *Daphne Mezereum* is from seeds, which, as a rule, are very freely produced. If sown when ripe and placed in a frame the seedlings will make their appearance during the following season. The varieties are usually grafted on to seedlings of the type, as they cannot be depended upon to come true from seeds. A limited number of the *Ceanothus* may form roots, but the best way to increase this by means of cuttings is to take the half-ripened shoots in August and dibble them into pots of sandy soil. A length of 4 inches to 5 inches is very suitable for cuttings, which should be cut off at a joint and the bottom leaves removed for the purpose of insertion. When this is done a good watering must be given through a fine rose in order to settle everything in its place. Then the pots should be stood in a cold frame kept close and shaded from the sun. Of course, it must be opened occasionally in order to examine the condition of the cuttings and to remove any decayed leaves. A great many shrubs can be increased in this way.]

Among the shrubs the spring display has begun. *Garrya elliptica* has seldom been in finer form, the catkins not only being more numerous than usual but longer than is generally the case. As regards this useful shrub little in the way of annual pruning is required, but any straggling or unnecessary branches or shoots may with advantage be removed. The best time to do this is immediately after the flowering is over. *Hamamelis arborea* is very attractive just at present. Suited by the rather peaty and moist soil in which the plants are growing, this Witch Hazel is making useful bushes and increasing in size annually. Any little trimming needful may be undertaken at the end of February. *Andromeda floribunda* is coming into flower and the display will be general in a few days. *Ribes sanguineum* will be earlier than has been the case for some years. What pruning or thinning is needed should, as in the case of the *Garrya*, be completed immediately after flowering. *Cotoneaster frigida*, *C.*

Simmonsii, and a stray Holly or two yet retain a good display of berries. This is uncommon in these gardens, for, as a rule, the fruits are eaten by birds long before this time. Azaleas, Rhododendrons, Kalmias, indeed, shrubs generally, are quite satisfactory. The one subject which refuses to grow here is the *Daphne*—usually an easily-grown and accommodating shrub, but which here struggles for a season or two and dies. The same thing happens in other gardens in the neighbourhood, and it is difficult to find a reason why this should be so. Soil and climate would appear to be quite suited to the needs of the *Daphnes*, so that there must be something in the soil which is fatal to success.—W. MCG.

Garrya elliptica, moving.—I agree with "E. M." as to this being impatient of removal. I once lifted some large plants, and, although they were planted at once, and very carefully, they never regained their former vigour. Some smaller plants lifted at the same time soon started into growth, and looked none the worse. Nurserymen generally send the plants out in pots, but I have found that these when rooted through suffered from the check.—DORSET.

PLANTS AND FLOWERS.

INDOOR PLANTS.

THREE BLUE WINTER-FLOWERING PLANTS.

It will be readily admitted that we do not possess any too many shrubby plants with flowers of this colour and that bloom in the dull season of the year. True, blue is not the best of colours under artificial light, but, none the less, these are all valuable by daylight for the flowering-house or semi-warm conservatory. A temperature somewhat above that of the ordinary greenhouse is needed—say 50 degs. as a minimum.

ERANTHEMUM PULCHELLUM.—I name this first as it has been grown much longer than either of those that will afterwards be treated upon. This is a plant of easy culture, really a subject for the cool stove. It is readily increased by cuttings every spring, and should be propagated in the early summer months, May being a suitable time. If inserted in Cocoa-fibre refuse and sand, with bottom-heat, the cuttings will soon root. Pot them off in good time, using good turfy loam, leaf-soil, and sand. Keep the shoots pinched during the summer months, growing the plants in nearly full sunshine. Cease to stop the shoots during early August. If one shift has been given after the first potting that will be ample, but do not repot after stopping has ceased. A second batch of cuttings will make most serviceable plants to flower during January and February. These may be allowed to flower in 3-inch or 4-inch pots, nothing larger. These plants will be very suitable as marginal lines in association with such as *Aphelandra aurantiaca* Roelzii. If these plants be grown on during the following spring a very useful stock will be the result. For cut flowers, too, they prove very useful.

COLEUS THYRSOIDEUS.—The colour of this *Coleus* is some tints lighter than that of the *Eranthemum*. It is a pleasing shade of pale, but bright blue. It will succeed well in a temperature somewhat cooler also. In order to obtain the long spikes of flowers a generous treatment is advisable, for when these are fully developed the plant is highly ornamental. Cuttings should be struck quite a month earlier than for the *Eranthemum*, as plants somewhat larger and more vigorous are essential. One more shift also is recommended; in other respects the treat-

ment may be the same. The plants will, naturally, be taller, more often 3 feet or so in height when the flower-spikes are developed. It is rather subject to both mealy bug and red spider, but these pests can both be kept in abeyance by a free use of the syringe. Water freely in this case whilst the growth is active, otherwise the oldest of the leaves will turn yellow and possibly fall.

PYCNOSTACHYS DAWELI.—This is a subtropical labiate from Africa. The flowers are very striking in their bright shade of blue. These are produced mostly in terminal fashion. The laterals do not appear to flower quite so freely, hence the plants are rather tall and straggling. The colour, however, makes up for all deficiencies in habit. If this plant were to be pinched rather more freely I think it would be advantageous. It should be also grown freely from its propagation onwards. For some time past it has been a striking feature in the flowering-house at Kew Gardens. When I saw it there lately I did not note any small plants, hence I am under the impression that it is not so suitable in that stage of growth. Both the *Coleus* and the *Eranthemum* were also noted there. H.

GREENHOUSE CLIMBERS.

A JUDICIOUS selection of climbing plants, provided they get reasonable attention, is a valuable addition to the greenhouse. That climbers are frequently not so satisfactory as they might be can be traced to various causes. The accommodation for the roots is often at fault. Climbing plants are often grown in pots or tubs, and when this is the case it should be borne in mind that a plant which covers a considerable amount of roof-space requires a corresponding supply of nourishment for the roots. This may be made up either by increasing the size of the receptacles or by giving an occasional stimulant during the growing season.

Another point that often leads to unsatisfactory results, particularly in small structures, is that strong-growing climbers are chosen for the purpose, so that, owing to the cutting away necessary to keep the vigorous shoots within bounds, the plants do not flower so freely as they would if more rationally treated. Such climbers as *Cobæa scandens* and some of the Passion Flowers are quite out of place in a small house, though for a large structure they would be very desirable. Attention may well be directed to another point, and that is that in the winter the plants in the greenhouse will require as much light as possible. It is, therefore, a good plan late in the autumn to prune the summer-flowering subjects—that have passed out of bloom. Of course, those that are still in flower or may be depended upon to bloom in the winter must not be treated in this way. Most climbers grow very rapidly during the season, at which time care should be taken to prevent them becoming a tangled mass, which is likely to happen unless they are attended to.

When climbing plants are trained to the roof they are particularly liable to be attacked by insect pests, owing in the first place to the dry atmosphere which prevails close to the glass, and next that being—at least in some cases—difficult to reach the pests may make a deal of headway before it is considered necessary to take them in hand. A liberal use of the syringe will greatly benefit climbers in general, that is, where it can be carried out without damaging the plants underneath.

Among the plants suitable for furnishing the roof or rafters of a greenhouse the best are, *Abutilons* of sorts, *Acacia*

Riceana, Clematis indivisa, Cliathus puniceus, Cobaea scandens, Fuchsias of sorts, Habrothamnus of sorts, Hibbertia dentata, Jasminum grandiflorum, Kennedyas of sorts, Lapagerias, Lonicera sempervirens minor, Mandevilla suaveolens, Passifloras of sorts, Pelargoniums (Ivy-leaved), Plumbago capensis and its white variety, Rhynchospermum jasminoides, Solanum jasminoides, Solanum Wendlandi, Sollya heterophylla, Streptosolen Jamesoni, Swainsonas of sorts, Tacsonias of sorts, Tecoma capensis, Tecoma jasminoides, and Tropaeolums of sorts. Of the above the Lapagerias succeed best in a cool, moist structure and a shaded position. Those that may be readily kept within bounds in

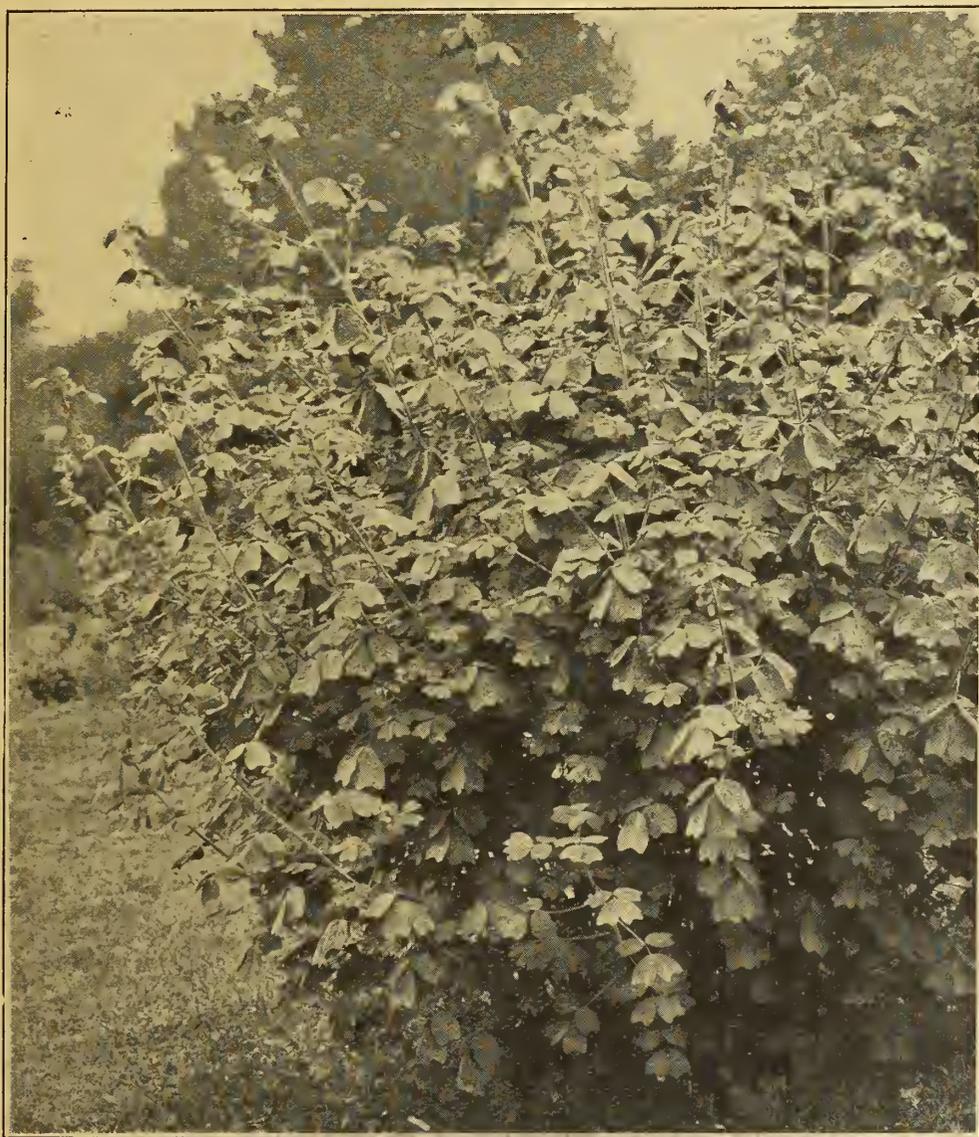

value of these plants during the dull months, it is pleasing to find that they can be grown in a temperature which does not exceed 60 degs.—KIRK.

AMICIA ZYGOMERIS.

THIS member of the Pea family, though a native of Mexico, has proved quite hardy in the south of Ireland, the more so as it is perennial and dies down in the winter. The effects of severe frost might be, therefore, mitigated by planting it deeply. It is worthy of cultivation, as it flowers in the autumn up to the time of frost. It grows some 9 feet in height and possesses an interesting peculiarity of growth, in that its stalks, with leaves and flowers, rise out of a pair of purple kidney-shaped

growth is unaffected. The result is that the lower parts of the plants are bare, and any young growth that starts there soon withers away.—W. H. S.

[The growths sent are exceedingly thin and weak, and bear evidence of a lack of good cultivation generally. We note, however, that the plants are two years old and have been grown in quite a cool house, hence the age of the examples and the treatment meted out to them may, combined, be responsible for the failing. The fact that the stems are bare and leafless is but the evidence of maturity, and two-year-old plants no more incline to leafy stems than do a Chrysanthemum or a Poplar when these become woody. Growers of the Carnation have frequently to clean

Part of a plant of *Amicia zygomeris* at Ashbourne, Glounthaune, Co. Cork.

a small structure would include Abutilons, Clematis indivisa, Fuchsias, Hibbertia dentata, Jasminum grandiflorum, Kennedyas, Lonicera sempervirens minor, Pelargoniums (Ivy-leaved), Plumbago capensis, Rhynchospermum jasminoides, Solanum jasminoides, Sollya heterophylla, and Tropaeolums. W. T.

Begonia Gloire de Lorraine.—I have, like many others, been accustomed to look upon this fine family of winter-flowering plants as requiring almost the heat of the stove. My opinion has been modified, for, having a spare batch, the plants were put into a greenhouse among a mixed collection of other winter-blooming subjects. These Begonias have bloomed freely, and at this date (February 20th) are yet quite good—long after those grown in stove heat are past. Considering the

bracts, which afterwards form collars round the stems. The flowers, which cover the shrub, are large, Pea-shaped, and golden-yellow in colour. It thrives in rich, light, well-drained soil, and delights in full sun. R. H. B.

NOTES AND REPLIES.

Perpetual and Malmaison Carnations.—Enclosed are samples of leaves taken from my plants, and I should be glad to know what is affecting them and the best means of arresting the spread of the disease. The plants (two years old) are grown in a cool lean-to greenhouse, facing south-east, and from which frost is kept out. Plenty of ventilation is provided. The house is dry and watertight, and the plants are not over-watered. As you will see, it is the older leaves that go off first, the attack commencing at the points, while the top

over their plants and remove dead or decaying material, and this appears to be necessary in your case. More necessary still, perhaps, is getting rid of the stock, since two-year-old plants, if they have done anything at all, are practically worn out. You had better purchase a fresh stock of vigorous young plants at once, as there is little hope of the old examples being of much further service.]

Pelargonium Paul Crampel.—When flowerbeds were being cleared in the autumn, a number of this Pelargonium was lifted and potted up, chiefly for the purpose of obtaining cuttings in spring. Having been cut back, these plants broke very freely, and in a warm pit they have bloomed very well almost throughout the winter. The colour is a telling one, and the flowers thus produced have been very useful for cutting.—KIRK.

VEGETABLES.

POTATOES: CHANGE OF SEED.

Most Potato growers have found that by getting at least a portion of their seed tubers from a distance they secure a proportionately higher rate of increase. Large growers in Lincolnshire and Scotland have for some years catered for this interchange of seed. I have looked upon this interchange as a means of increasing the yield by about a third compared with that obtained from home-saved stocks. In some soils deterioration is more rapid than in others, but I am inclined to the opinion that in most gardens, be they large or small, there is greater satisfaction derived by purchasing at least a portion of one's stock. Many claim to have derived the greatest advantages from Scotch-grown seed; others again will have found the climatic changes too severe and the yield less than was anticipated. After repeated trials I have come to the conclusion that Lincolnshire seed affords a greater range of profit than do purchases from further north. Lincoln growers, I believe, obtain their seed from Scotland, and thus find the same advantages that we derive from their county. It would seem that only within recent years has it been found what an influence there is in climate as affecting Potato growth and crop. Ireland has sent her quota, and it is found by some that results compare favourably with those from Scotch and English seed. Cambridge and Hunts, too, have now for some time been in the field. In this time of war, when everyone is urged to provide the maximum of food stuffs from the land, the question of the most suitable seed-stock should be taken into consideration. I hold no brief for any county. I have satisfied myself that in this county seed tubers from Lincoln give me a maximum of Potato yield. These remarks apply not only to the early-maturing stocks but equally to maincrop varieties. W. S.

Wills.

RAISING EARLY CAULIFLOWERS UNDER GLASS.

THE winter up to the present has been exceptionally favourable for the Broccoli crop. When Broccolis are plentiful it is a waste of effort and space to forward Cauliflowers that will come in at a time when Broccoli is plentiful. Given good culture and care in the selection of the varieties, Broccoli will keep up a supply of good heads through the month of May and often well into June. That being so one need not sow the early Cauliflowers until February is well advanced, when a slight hot-bed and frame can be provided for them. The hot-bed may be dispensed with if there is no urgency in the maturity of the crop, a small frame in a sunny position answering the purpose. When forced under glass Cauliflower plants are made somewhat tender, and I have known them badly crippled when overtaken by spring frost. Inverted flower-pots placed over the plants at night have been a means of saving them when unprotected plants have been hopelessly crippled. When hot-beds are impossible the seed can be sown in boxes, standing in a warm greenhouse and bringing on gradually until the plants can be trusted outside. The small-growing early forms of Snowball, of which there are many selected stocks now on the market, are those I would choose. I find it a good rule to sow at the same time some of the Autumn Giant, both of the extra early selected stocks, and the normal types. These need a longer season of growth and are much more dependable

than are the others if overtaken by stress of weather. These extra early stocks may be depended on to furnish successional supplies from the end of July onward if given an early start and good culture. In some households Cauliflowers hold a very high place, and when this is so then every available means of securing a supply is justified. W. STRUGNELL.

GARDEN FOOD.

THE USES OF ORANGES.

It is not generally recognised that Oranges possess valuable qualities, such as citric acid, and an abundant supply of potash salts, as well as lime and magnesia. This fruit is well adapted to salad-making, and the following are some suggested combinations which are unusual but very delicious:—Orange and Celery with French dressing served with game; Orange, Chestnut, Raisin, and Celery, and French dressing with either game or chicken; Orange and Grape-fruit dressed with French dressing and served with fish or roast pork. As a sweet the following are excellent:—

ORANGE AND BANANA SALAD.—Ingredients: Three Oranges, three Bananas, two tablespoonfuls of desiccated Cocoanut, one teaspoonful of loaf sugar, one teaspoonful of water. Method: Remove the peel and all the white pith from the Oranges, and cut them into thin slices with a sharp knife. Skin and slice the Bananas, and arrange the fruit in layers in a salad-bowl, sprinkling each layer with a little of the Cocoanut. Put the sugar and water into a saucepan and let them boil for ten minutes. Allow the syrup to cool and then pour it over the fruit, and place in a cool place until wanted. This is much better if made some hours before being served, as thus the fruit has time to absorb the flavour of the Cocoanut.

ORANGE TART.—The same combination of fruits is used for this recipe, resulting in an excellent dish, the acid of the Oranges supplying what is needed in this respect in the Bananas. Peel and slice six Bananas and three oranges, and arrange them in a pie-dish, sprinkling them with chopped Nuts and brown sugar. Cover with pastry and bake in a moderate oven for about three-quarters of an hour. This will be sufficient for four or five persons.

GELÉE D'ORANGE.—Ingredients: $\frac{1}{2}$ pint of Orange-juice (this will take four or five Oranges), the rind of two of the Oranges, 4 oz. of loaf sugar, 1 oz. of sheet gelatine, $\frac{1}{2}$ pint of water, the rind and juice of one Lemon. Method: Wipe the Oranges and Lemon with a damp cloth, and then peel—very thinly—the rind required. Put this into a saucepan with the gelatine, sugar, and water, stir over the fire until the gelatine is dissolved, and then simmer for ten minutes. Strain this mixture into a basin and to it add the strained Orange and Lemon juice; stir until it begins to thicken, then pour into a wetted mould, and set aside to cool.

ORANGE MARMALADE.—Ingredients: $3\frac{1}{2}$ lb. Oranges, three Seville Oranges, $15\frac{1}{2}$ pints of cold water, sugar, $\frac{1}{2}$ pint of boiling water. Method: Wipe the Oranges with a damp cloth and cut them in halves. Squeeze the juice out on a Lemon squeezer, and then strau it into a basin. Put the pips into a small basin, add the boiling water, and let them stand to extract the flavour. Cut the skins of the Oranges into strips, not too thin, and put them into a large basin with the cold water; let them soak for twenty-four hours. Now put into a preserving-pan, and boil until the peel is tender; boil the pips for fifteen minutes, and then strain the water from them into the preserving pan. When finished cooking pour all into a large basin, add the Orange juice, and let it stand for at least twelve hours. Next day measure the liquid, and to every pint allow 1 lb. of preserving sugar. Boil again for about twenty or thirty minutes, then pour into pots and cover while hot.—*Guardian.*

NOTES AND REPLIES.

D'Arcy Apple.—"Now that Cox's Orange Pippin is out of season, by far the best dessert Apple that I have ever tasted is D'Arcy Spice Pippin, which was improperly re-named Baddow Pippin, and is known by the latter designation to many people. By the way, it seems to me that no encouragement, or even tolerance, should be accorded to men who re-name an old variety. The Apple mentioned is quite as spicy as Cox's Orange Pippin, but less sugary. It is vastly superior in flavour to

Claygate Pearmain, Duke of Devonshire, or Mannington's Pearmain—all three late keepers."

[The above is from the *Gardeners' Chronicle*. For years I have done my best to help on the cultivation of this Apple. The nurserymen tell me it is a bad grower. I do not believe it. Slow it may be, and not like some of their stocks. The best name for it is the D'Arcy Apple—"Pippin" and "Spice" are alike unnecessary.—W.]

The Chinese way with Tea.—The winter-feeding of cattle is often of a kind that imparts a disagreeable taste to milk and cream. This is so unpleasant to me that I gave up milk and cream and began to look into the Chinese way of taking Tea. It is very much more pleasant than the common way, by which Tea-drinking is degraded to a totally different thing from what it was originally. The Chinese use boiling water and a pinch of a good Tea, and add nothing more except a slice of Lemon. This means that the pure water enters the blood at once with a little flavouring of tea. I had a choice of three Teas, namely, Nynghow, Caravan, and Formosa Oolong. I chose the last, and like it very much. It is a little dearer than ordinary Tea, but one uses very little of it, so that it is really more economical. I get mine from Ridgway's, 182, Oxford Street, London. The addition of milk, cream, and sugar to Tea is a call on the digestion. The over-drawn and inferior Tea with plenty of sugar and milk is a cause of dyspepsia, and many would do well to turn back to the Chinese way. A saltspoonful of Tea is enough for each person. The Tea should be drawn not more than a minute or two. If any sugar be desired use a very little.—W.

Cape Broccoli.—I have sent you a sample of the real Cape Broccoli. It is distinct from the Purple Sprouting Broccoli, which never comes to a large head, but in small shoots. The seed may be obtained from Messrs. Watkins and Simpson, Tavistock-street, Covent Garden, who supplied the seed for the enclosed sample to Mr. Lob-jolt, who is one of our largest market gardeners. It is known in Covent Garden simply as Cape Broccoli.—H. A. CHANTER.

[A distinct vegetable, and like the Purple Broccoli. We have too many Cauliflowers of poor flavour, but this has a delicate and good flavour and not a trace of the unpleasant bitterness of many Cauliflowers.—Ed.]

Salad-dressing.—Some object to the use of oil and, with better reason, the ordinary British salad-dressing. They may take courage when we say that a well-chosen salad, winter or summer, is best without any dressing. One gets the true flavour of things and avoids doubtful mixtures.

Carrot French Forcing or Parisian.—At page 72 "J. S." asks for information as to growing this. To get Carrots at the earliest date at the close of the year I made up in a brick pit a bed consisting of manure and Oak leaves. When settled, about 6 inches of good, light, sifted soil were placed over this. On this the seed, with a few early Radishes, was sown, and when the seedlings came up abundance of air in favourable weather was given, with ample moisture. About mid-April I began to pull nice tender roots. At the same time a sowing was made, in the same kind of soil, in the open to keep up a supply through the season.—DORSET.

Celery crisp and good.—Has "W." ever tried Major Clarke's Solid Red or Standard Bearer Celery for use after the New Year? The former is the earlier of the two, not large, and very crisp. Standard Bearer is of medium size, and, like Major Clarke's Red, of superior flavour. Regarding White Celery, Wright's Grove White is a good sort; but I find the red varieties preferable, as white Celery is apt to rot in the early part of the year. This season has not been particularly favourable for Celery, but the two red sorts above mentioned have done well.—KIRK.

OUTDOOR PLANTS.

A LANDSCAPE AT KEW.

The most interesting part of Kew to the student of landscape gardening or planting is away from the flower garden and all that geometrical arrangement about the big houses. The Rhododendron dell at Kew, here figured, is an example of good planting and good gardening, and is a lesson as to what can be done in our climate.

The accompanying illustration directs attention to one of the most popular features of our national Botanic Garden, for in addition to its containing a representative collection of the best of

cluded. Here and there groups of Box and Holly with an occasional Yew were planted about the margins of the woods and on the banks of the valley. In course of time, when Rhododendrons became popular, this valley was considered to be an ideal place for them, and probably plants were placed in position three-quarters of a century ago. Twenty-five years ago, however, the Dell was by no means so beautiful as it is to-day. At that time it had become overgrown, and a considerable number of the finest specimens were the common *R. ponticum*. It was, however, taken in hand, badly-placed trees were cleared, common Rhododendrons were removed to the surrounding woods, good kinds were given more room, and

Pine, which originally stood on the right-hand side of the section shown in the picture, was a severe blow to artists, for they had been included in many pictures, but they became dangerous, and duty to the general public necessitated their removal, their places being now taken by Rhododendrons. From near this point, entrance is gained to the Bamboo garden, another interesting feature.

One of the finest bushes in the picture is *R. Broughtoni*, a vigorous variety with large foliage and very fine heads of rosy-crimson flowers. *R. Nobleanum* is also represented here by a fine bush, and elsewhere in the Dell by two large groups. The uncommon *R. Luscombei*, an early kind with large, fragrant, rose-coloured

The Rhododendron dell in the Royal Gardens, Kew.

the garden Rhododendrons, it has been tastefully designed and planted so that the various specimens are shown in a natural manner without the slightest formality. It serves as an object lesson as to what may be accomplished with a perfectly level field, for what is now a valley was at one time level ground. The change was brought about during the reign of George III., the design being the work of "Capability" Brown, the actual work, together with the connecting paths, being, it is said, the work of the Staffordshire Militia. The ground on either side of the Dell was planted with common timber trees, the most prominent being Beech, Sweet Chestnut, Oak, and Elm, with a few Lebanon Cedars and Weymouth Pines, odd large-growing trees of other sorts being in-

up-to-date kinds were procured, so that in the course of time the present condition was reached.

In addition, the planting has been extended by opening out a side valley at the south end and by planting the ground about the top of the slopes at either end with Rhododendrons. When removing superfluous trees care was taken to retain the Cedars and the various groups of Box and Holly, together with a number of fine specimen trees, and the usefulness of these is well illustrated at the northern end of the valley, where large Hollies and Rhododendrons are charmingly intermingled and where a magnificent specimen of the London Plane tops the bank and spreads its shade over a very wide area. The death of several old examples of Weymouth

flowers, also enters into the picture; other large plants being *R. campanulatum*, *R. purpureum elegans*, *R. Fortunei*, and *R. Cunninghami*. At the south end of the Dell is a group of the fragrant Kew hybrid *R. kewense*, and a few of the many varieties found elsewhere are Pink Pearl, Gomer Waterer, Michael Waterer, Sappho, Queen, Sigismund Rucker, Doncaster, Lord Palmerston, Mrs. John Waterer, Manglesi, Mrs. Holford, Lady Grey Egerton, and catawbiense.

As a rule, Azaleas or deciduous Rhododendrons are confined to the Azalea garden, which stands some 200 yards to the east of the Dell, but a mass of the yellow-flowered *R. flavum* has been included with the idea of introducing a colour which was only present in the pale yellow *R. campy-*

locarpum. A group of Camellias about half way along the valley is an interesting feature, for the plants are thoroughly hardy, and they usually blossom freely. On all sides the plants are surrounded by Grass, except, of course, where they have encroached upon the central gravel path.

Although the Rhododendron Dell contains a fair number of species, it is chiefly planted with garden hybrids and varieties, a large collection of species finding a congenial home in the vicinity of King William's Temple, near the north end of the Temperate House. D.

NOTES AND REPLIES.

The Jalap plant.—I am anxious to grow the Jalap plant, which I have seen described in GARDENING ILLUSTRATED, also in "The English Flower Garden." I understand it is sufficiently hardy to grow out-of-doors in this county, and I, therefore, presume it does not object to lime in the soil. I thought of putting it in, in a well-drained border against a 7 feet wall facing south, where it would get all the sun possible. Would this be a suitable position? When ought the tubers to be planted, and how deep? Will they require protection in the winter? How much head room would the plant require? Would the soil require much enriching before planting the tubers? Do they want any stimulant in the summer, or water?—G. STRICKLAND, Poulton, Fairford, Gloucester.

[You have a good idea what to do to begin with. Plant at the foot of your warmest wall, if near a wall shrub all the better. We have never given any protection. Give all the head room you may. Give good, free soil, no need for much enriching. Judging by the fine way the plant does at Hillbrook Place, a chalky soil suits it, but it is not essential. We got our plants from Barr's nursery at Taplow, and much depends on getting good roots. The plant comes rather late into flower, and wants all the sun that comes to us.—Ed.]

Iris Danfordiæ.—This came to me a good many years ago from the late Herr Max Leichtlin, when he distributed it under the name of *I. Bornmuelleri*. It is now generally recognised that *I. Bornmuelleri* and *I. Danfordiæ* are the same, and that the latter name should have the preference. It is a remarkably neat little Iris of the reticulata group, and the only one which has yellow flowers. It has a marked peculiarity in the small, almost suppressed standards. It is only about 3 inches high, and when in bloom, which is generally in February, is quite bright with its golden-yellow, brown-spotted flowers. Unfortunately, *I. Danfordiæ* does not take very kindly to our climate, and I have lost it several times. I cannot remember retaining it for more than two years in the open, although covered with a hand-light during the flowering period and for some time afterwards. I grew it on sunny rockwork in loam, peat, or leaf-soil and sand, planted about 2 inches deep. It is a beautiful Iris for pots.—S. ARNOTT.

Double-flowered Godetias.—Many who object to double flowers might modify their opinion were they to give the double-flowered forms of *Godetia* a trial. The flowers are by no means heavy; on the contrary, they are almost as elegant in character as those of *Clarkias*. These *Godetias* are perfectly hardy, and, as the spikes of bloom run from 2 feet to 2½ feet in height, they are very useful for cutting. The double rose, double lilac, and double crimson are all worthy of attention, producing quantities of flowers for indoor decoration during the late summer and autumn from sowings made in April.—Kirk.

The Persian Tulip.—In this we have a charming little Tulip species which might be more largely utilised for the front of the border or the rock garden. It is well suited for either position, especially as it is one of the species which does not call for frequent lifting and resting, as is the manner of some. I have had it for years in the same position, increasing in numbers, if slowly, and blooming freely. The flowers, which open out almost flat to the sun, are large for the size of the plant, which is only some 6 inches or 9 inches high. The flowers are bright yellow, marked on the outside with a ruddy bronze.—S. ARNOTT.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM FEBRUARY 17TH.—*Arbutus canariensis*, *Oso Berry* (*Nuttallia cerasiformis*), *Berberis* (in variety), *Daphnes* (in variety), *Periwinkles* (various), *Forsythia suspensa*, *F. spectabilis*, *Andromedas*, *Rhododendron Nobleanum*, *R. praecox*, the *Purple Plum* (*Prunus Pissardi*), *Cydonias* (in various colours), *Edgeworthia chrysantha*, *Yellow Jasmine*, *Coronilla glauca*, the *Cornelian Cherry*, *Ericas* (in great variety), *Ribes sanguineum*, the *Goat Willow* (*Salix caprea*), *Alnus*, *Hazels* (in variety), *Azara microphylla*, *Saxifragas* (in variety), *Snowdrops*, *Violets*, *Primroses*, the *Greek Anemone* (in many shades), *Anemone Hepatica* (in variety), *Anemone nemorosa*, *Narcissus pallidus praecox*, *N. minimus*, *N. Tozzetta*, *N. Grand Monarch*, *Tenby*, *Crocus* (several species and varieties), *Cyclamen Coum*, *Iris unguicularis*, *I. reticulata*, *Snowflakes*, *Lenten Roses* (in many shades), the *Corsican Hellebore*, *Aubrietias*, *Puschkinia scilloides*, the *Bitter Vetch* (*Orobus vernus*), *Iberis* (in variety), *Scilla sibirica*, *S. taurica*, *S. campanulata*, *Muscari botryoides*, *Dog's-tooth Violets*, *Violet Cress*, *Aconites*, the *Scarlet Windflower*, *Corydalis cheilanthifolia*, *Blue-eyed Mary* (*Omphalodes verna*), *Triteleia uniflora*, *Anemone coronaria* (in various colours), *Chionodoxas*, *Hyacinthus azureus*, *Viola gracilis*.

WORK OF THE WEEK.—The forking over of shrubberies is still being pushed on, as where large vacant plots are left for the sowing of annuals it is advisable to get the soil well exposed to the weather before sowing. A small stream which runs through beds of Red Willows—with a few clumps of Japanese Iris studding its banks—has been cleared of all decaying foliage in order that its course may be clearly seen. Groups of the large Water Forget-me-not appear at intervals in summer, and a few seeds of Watercress are scattered along its banks when the winter rush recedes. A small group of the Red Dogwood has been planted, the soil being stiff clay. A group of Pampas Grasses growing near the waterside has been thoroughly cleaned. The foliage was first of all set on fire in order to clear out the accumulations of several years, and afterwards cut over close. This is a very good plan when Grasses of this description have become overcrowded with old foliage, as the burning does not injure them. The cutting and preparing of Willows for tying have been carried on during bad weather. A start has been made with the pricking over of Azalea beds. This requires care, and should only be done where the shrubs are not crowded. Crocuses are very pretty among Azaleas, and increase rapidly on warm soils. Some spare plants of *Epimedium sulphureum* have been planted in a long line as an edging, replacing a Grass verge, which had to be cut by hand, thus saving time. A large group of *Vaccinium pennsylvanicum* which had become very old has been grubbed up and in its place a group of *Andromeda japonica* has been planted, linking up with other established shrubs of the same kind. Having about fifty plants of *Rhododendron maximum*—an American species—it was decided to plant them in one of the home woods. A favourable position has been cleared, and the plants put out 6 feet apart near a ride which will shortly be gay with Daffodils. A further plantation of the *Nootka Cypress* has been made on a poor clayey ridge, and a hedge has been made of two-year-old Quicks. Two large specimen

Pomegranates which have been growing in tubs, but rarely produced flowers, have been planted out in a favourable position at the foot of the fruit wall. E. M.

Sussex.

SOUTHERN COUNTIES.

Peas.—A further sowing of Peas in the open has been made, the rows standing 6 feet apart, which allows of two rows of early Potatoes being planted between them. To ensure a good succession of Peas two varieties of a second early and one of a maincrop sort were selected. The drills are drawn 6 inches in width and about 3 inches in depth, in which the seeds are scattered with a less liberal hand than was the case at the previous sowing. The soil is now in capital condition, there being not the slightest difficulty in obtaining an ample quantity of the finer particles with which to cover the seed.

Turnips.—Winter Turnips are holding out well, but they will be over before the earliest crop raised this season is fit for use. To render the interval as short as possible seed of Early Milan will be sown at once on a south border and protected with Pea-guards, for the twofold purpose of preventing birds destroying the plants as they appear and that, in case of emergency, they may be shielded from severe frost either with mats or litter. Another sowing of the same variety, and a good one of Early Snowball, will take place, weather permitting, in a fortnight.

Short-horn Carrots.—A first sowing outdoors of this will now be made. The plot selected is not only sheltered, but owing to its position enjoys a maximum of sunshine. The seed will be sown in drills, one half of the plot with Inimitable Forcing and the other half with Early Gem.

Potatoes.—Contrary to anticipation, late Potatoes have kept well, and the quality leaves little to be desired. They now require turning over and the shoots rubbed off from those which have started to grow. To prevent them making more growth than can be avoided the store will be kept as cool as possible. The seed tubers of these late varieties will be laid out in another place, which, to prevent premature growth being made, will be thoroughly ventilated.

Strawberry-beds.—The plants will now be relieved of dead leaves and a suitable fertiliser strewn on the soil between the rows and hoed in. Should any gaps in the rows have been over-looked at planting time they will be made good with pot-plants intended for late forcing.

Pinks.—These were replanted last season, the method pursued being the rough-and-ready one of selecting tufts of young growths from the outside of the old plants and planting them with a trowel 9 inches apart each way, in a long border 3 feet to 4 feet wide. Out of the hundreds of tufts so planted scarcely a dozen have failed to grow. The remainder look remarkably well and have had the vacant spaces between them lightly stirred to get rid of weeds and aerate the soil. In the course of a few weeks a light dressing of Carnation manure will be applied and hoed in.

Border Chrysanthemums.—The majority of the plants having made a good start will now be placed in a cold pit and gradually hardened off, with a view to getting them planted out as early as circumstances permit. Those not quite ready, or of which stock is still scarce, will be kept in slight warmth a short time longer.

Tomatoes.—The plants required both for main crop under glass and for growing outdoors will now be raised in gentle

heat. Seven-inch pots, well drained, and filled with light, loamy compost, will be employed for the purpose, and the seed, in order to avoid drawn and weak plants resulting, will be thinly distributed on the surface and lightly covered with fine sandy soil. Well-tried varieties which in the past have yielded satisfactory results are chiefly relied on.

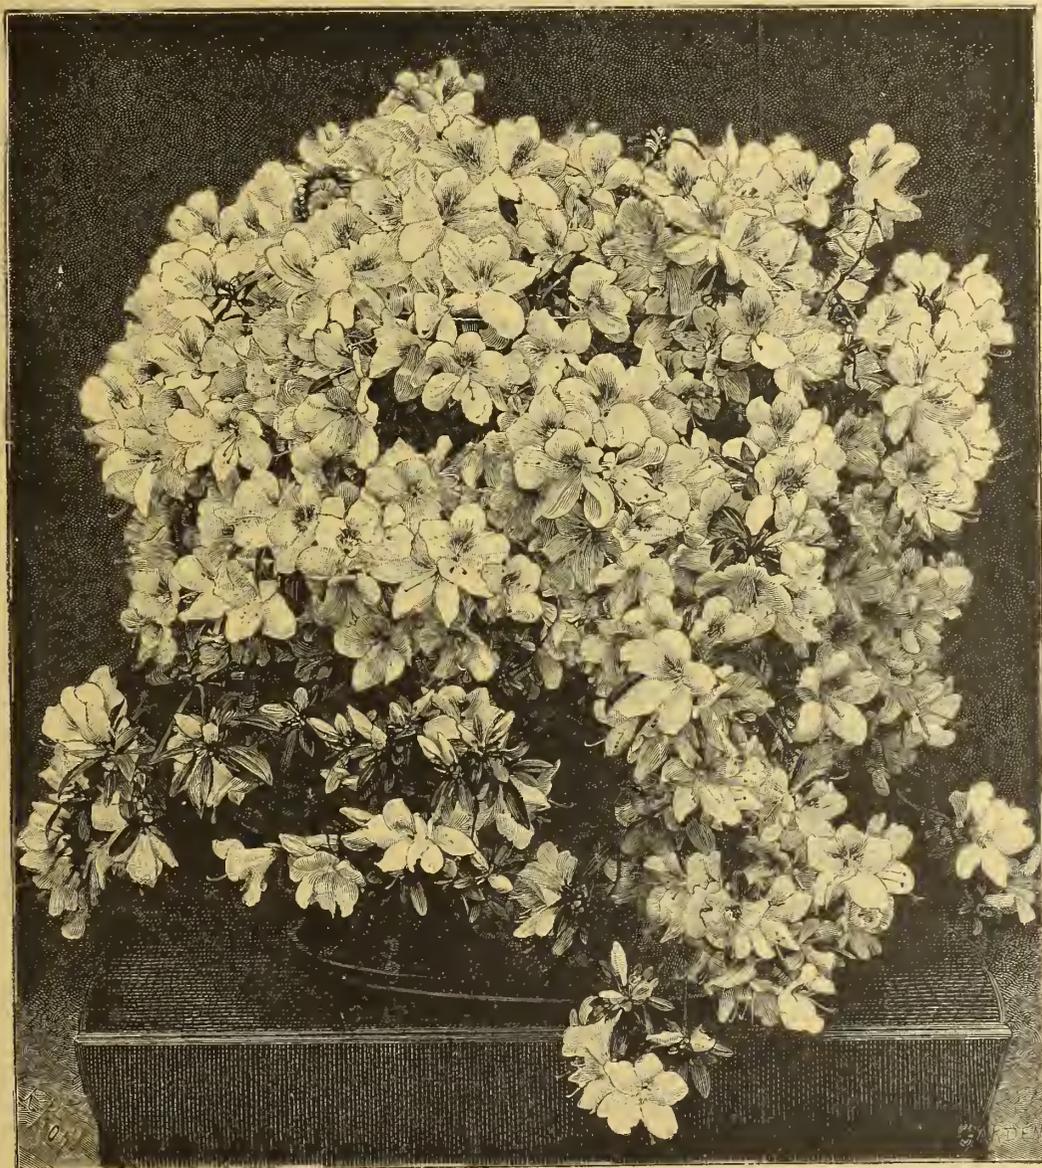

Muscat Grapes.—These will now be started. The Vines have had a longer rest than usual. When the house is closed, the border, after having been dressed with a fertiliser, will be well moistened with tepid water, and a humid atmosphere, with the aid of daily syringings and

comes necessary both by day and night. The starting of this house places more shelves at disposal for the forwarding of Strawberries in the initial stage of forcing, but care has to be taken not to leave them too long in the house in case red-spider should put in an appearance and lead to the foliage of the Vines becoming infested.

Cucumbers.—Plants raised from seed sown early last month should be planted without further delay. With an increase of daylight, combined with a good sharp heat both top and bottom, the plants will make rapid progress once the roots get to work in the compost made up in the form of mounds near to the front wall of the

Market, Every Day, and a good strain of Telegraph, are best.

Early Melons.—These should now be planted out, keeping the balls somewhat higher than the surrounding soil in the pots, so that water will drain away from the stems and so avert risk of canker. Planting needs to be carefully done, and not only should breaking of the balls when knocked out of the pots be avoided, but the holes should be opened large enough to receive them, so that soil can be worked in round them and made firm with a potting-stick. A soaking of tepid water then settles them into place, after which sticks to tie the plants to until they

A naturally-grown Azalea.

damping footpaths and dry surfaces, maintained. The temperature for starting will be 50 degs. at night, 55 degs. by day, with a further rise of 15 degs. with sun-heat before admitting air by the top ventilators. To economise fuel the valves will be shut off early in the morning whenever the day promises to be bright, and closing for the day done sufficiently early to command a temperature of 80 degs. to 85 degs. Artificial heat will then not need to be turned on until the thermometer indicates a near approach to the night temperature, and then only sufficient to keep it at the figures stated. As soon as the buds begin to swell, and are on the point of breaking, a further rise of 5 degs. be-

house. Tepid water, both for watering and syringing, being necessary, a bucket should be placed on the pipes and kept filled for the purpose when there is no other means of obtaining it. Compost for top-dressing should also be kept in readiness and be placed somewhere for a day or two before it is required for use to get the chill off. Strict attention to these simple details makes all the difference in the progress the plants will make and the time they commence bearing. Seed should be sown now to provide plants for growing in frames or hot-beds, or in pits into which a good bed of fermenting materials can be introduced. For general purposes free-fruited varieties, such as Pride of the

reach the trellis are placed one behind each plant. A top heat of 70 degs. to 75 degs. by day is necessary, and from 65 degs. to 70 degs. by night. The bottom-heat should not fall below 80 degs. nor exceed 85 degs. A. W.

MIDLAND COUNTIES.

Early Peaches under glass.—The fruits in the earliest house are now swelling freely, and the temperature at night may be increased to 60 degs. unless the weather is very cold, when 5 degs. less are sufficient. Disbudding should be done gradually—at intervals of a few days—eventually leaving one shoot at the base and one at the point of the fruiting wood, ex-

cept where it is desirable to encourage young wood so as to allow of the subsequent removal of bare and old branches. Care must be taken that the trees do not suffer from want of water, and in the case of old trees carrying good crops plenty of stimulants may be given. The trees must be thoroughly syringed on fine days or red spider will be troublesome. If the trees are attacked with this pest syringe with a solution of Quassia extract and sulphur on two or three successive days. The trees in late houses which it is desirable to retard as long as possible must not be allowed to get dry at the roots or bud-dropping will result. They should also be syringed on fine days. Fumigate the house before the trees come into flower.

Begonia Gloire de Lorraine.—Plants that have been cut back are now making young shoots. These will be taken off when $1\frac{1}{2}$ inches to 2 inches in length and inserted in pots to provide a batch of plants for early flowering. These strike readily if inserted in pots of sandy soil and placed in the propagating-pit or under a hand-light in the stove. If the Begonia mite has attacked the stock plants dip the cuttings in weak Tobacco-water before inserting them, and make every effort to keep the pest under. Cuttings for successional batches will be inserted later as required.

Chrysanthemums which are well rooted in small pots will shortly be transferred to 48's or 32's, according to the strength of the plants. The soil for this potting should not be too rich, good fibrous loam, leaf-soil, and sand being a suitable compost. If the loam be heavy or stiff add plenty of coarse grit. After potting, place the plants in a cold pit or frame and shade lightly for a few days if signs of flagging should appear. Water carefully and air freely by tilting the lights, and when the plants are established in the pots remove the lights during the day upon every favourable opportunity.

Forced shrubs.—As these pass out of flower they are placed in a house with a temperature of about 55 degs. to 60 degs. to make their growth. Many require cutting back, but not so hard as when growing in the open. Pick off all old flowers and seed-vessels, taking care not to injure the young growing shoots. Repot any that require it, taking care not to over-pot. Syringe the plants morning and afternoon, and afford liquid manure-water to those not repotted.

Globe Artichokes are often allowed to remain too long without division and in one spot. It is important to maintain a supply of this vegetable for as long a time as possible, and the cultural details that should be adopted to extend the season may well be considered at this season. It is a good plan to take up a part of the plot (say a third of the total number of plants) each year, divide them carefully into pieces having two strong crowns, and replant these, three in a clump 4 feet apart each way. The ground intended for this crop should, without delay, be prepared by trenching and working in plenty of farmyard manure. Transplanting may be done at the end of the month, choosing a mild, dull day for the purpose, as, if sunny or windy, the roots soon become dry, and harm will result. The work should be done as quickly as possible, and when completed give a good soaking of water to settle the soil about them.

Broad Beans.—The main crop of these will now be sown on an open break, 3 feet from row to row and from 4 inches to 6 inches between the seeds. Favourite varieties are Improved Green Windsor and Mammoth Longpod.

Peas.—As soon as the ground and weather permit, seed will be sown in quantity on ground that has been deeply trenched and well manured. Drills should be drawn out in the early part of the day and the Peas sown in the afternoon, sowing rather more thinly than was the case with the earliest lot. Leave ample room between the rows. At least three different varieties of Peas should be sown at this date. As soon as the early sowings show above ground it is a good plan to dust frequently with soot to ward off slugs, etc., earthing up and staking the plants as soon as they are a few inches high. Keep a sharp outlook for sparrows, which pick off the tops. Peas raised under glass are kept cool, and will be well hardened off before they are planted on a warm border. When planted they will be staked forthwith and protection afforded on the more exposed side of each row.

Herbs.—The herb border should be given attention at this season. Perennial herbs require lifting and transplanting every three or four years. Mint, especially, should be attended to in this respect or the stems will become wiry and the leaves very small. If not transplanted a good top-dressing of rich soil should be afforded without delay. Transplant Tarragon, Thyme, and Pot Marjoram. Sorrel can be either transplanted or raised from seed. If transplanted, all the flower-stems should be broken out as they appear, or small leaves will result. Sage is easily raised from seed or increased from cuttings struck in the autumn. Chervil may be sown now, choosing a warm corner for the first sowing.

Annuals.—Seeds of various kinds of annuals will be sown now. There are many which may be sown out of doors in their flowering quarters as soon as the soil is in a suitable condition, but many are better raised under glass and pricked out into frames. Antirrhinums sown in pans in January have been pricked off into boxes of light soil and are making good progress. Of these the Intermediate varieties are the best. Planted in masses some of the varieties are splendid and make a gorgeous display throughout the summer. In the present month there is much to be done in the way of

Propagating summer-flowering plants, both by seeds and cuttings. *Salvia patens* gives us one of our finest blues and is indispensable. It can be raised from seed sown in heat, or from cuttings obtained from tubers which have been placed in heat.

Begonia tubers which have been resting during the winter may now be placed in heat. Keep them in a moist, warm atmosphere till they have made considerable growth, when they can be planted in a frame.

F. W. GALLOP.

SCOTLAND.

Ferns under glass.—Ferns are now growing freely, and the present is a good time to undertake any needful repotting. *Adiantums* of all kinds, with the possible exception of *A. Farleyense*, appear to relish a little finely-sifted lime-rubbish in the compost, and where this is given less sand may be used. Peat is sometimes recommended for Ferns, but if some well-decayed leaf-mould and a few nodules of charcoal, together with well-rotted fibrous loam are used, peat can quite well be dispensed with. Such a mixture will be found suitable for Ferns generally, but *A. Farleyense* thrives best in pure loam without even the addition of sand. When repotting, the older fronds may, with advantage, be cut cleanly out, a pair of Grape-scissors being very useful for this purpose. In the case of large specimens

in 10-inch pots there is no necessity for the usual annual repotting, but in such cases free supplies of weak soot-water or of well-diluted liquid manure must be given from now onward. In the case of all Ferns, after repotting has been completed, watering ought to be in careful hands, and the plants must be shaded from the direct rays of the sun for a time.

Selaginellas and Lycopodiums, like Ferns, are also showing new growths, and the plants may be broken up and repotted. These useful subjects, I think, are much more valuable when grown in good-sized shallow pans than in pots. The general cultural details applicable to Ferns will be found suitable in the case of *Selaginellas* and *Lycopodiums*.

Bulbs.—Dutch Hyacinths are useful at this time, and by bringing them into heat a few at a time the season is prolonged. Of course, with the advancing spring, these bulbs are, naturally, making progress, and very little artificial heat suffices to bring them into bloom. Other useful bulbs at this time include some of the larger *Narcissi*—*Sir Watkin*, *Golden Spur*, *Monarch*, and *Emperor*, among others. When in bloom if given cool greenhouse treatment the flowers have more substance and the stems are not unduly long and spindly. Apart from their use for greenhouse decoration the blooms of such *Narcissi* are of much service when cut, and when so used nothing harmonises so well with them as their own foliage. The bulbs will be given cooler treatment after flowering, but watering will continue till the foliage ripens off, when they will be planted out in the bulb quarter to recover.

Swainsonia galegifolia.—Some cuttings of this plant having been procured, these were put into the propagating pit. This is a greenhouse plant of some merit, and was formerly met with much more frequently than is now the case. While it succeeds well enough in pots, perhaps it is seen to more advantage when grown up a pillar or rafter, its lilac-blue Pea-shaped blooms being freely produced over an extended period.

Sweet Peas.—A further lot of Sweet Peas has been sown in the course of the week. These consist entirely of the old *grandiflora* varieties, which, after all, are quite as handsome as, and, I think, more sweetly perfumed than, the Spencer types of Sweet Peas. A good quantity of the ever useful white, *Dorothy Eckford*, was included. This is still one of the best, if not quite the best, of the white forms. *Jeannie Gordon*, *Lovely*, *Prima Donna*, *Lady G. Hamilton*, *Helen Pierce*, *Miss Willmott*, *Zarina*, and *Black Knight* are also among the old favourites sown at this time. While the Spencer varieties previously sown will be used in clumps and on wire pillars, the *grandiflora* varieties will be grown in lines, and for cutting they are quite as useful as the *Spencers*, and much less liable to be affected either by weather or by disease.

Hardy flower borders.—Owing to a decided improvement in the weather much progress has been made with the delayed work among the hardy plant borders. Forking and digging, together with a little re-arranging, have been well forwarded during the week, and it is hoped to finish the work in the course of the ensuing week. Among other things planted was a good number of *Lupinus polyphyllus*. These plants were grown in beds during last year from seed. Stray seedlings bloomed, in late autumn, and now they have been planted in good colonies through the borders, and may be expected to give a good account of themselves. An effort was made to thin out the roots of *Physalis Bunyardi*—an ex-

tremely fine Winter Cherry, but a trifle inclined to take possession of more than its allotted space. In the course of the work it was noticed with regret that a fine piece of *Phygelius campensis* has succumbed, owing, most probably, to the prolonged wet. I have always been rather suspicious of the entire hardness of this splendid plant, but as it has endured without injury some rather severe winters it appears that damp is more to be dreaded than frost. A comparatively large area, in which many different kinds of *Narcissi* and of *Tulips* are grown, was also during the week forked lightly over. Previous to forking a good dressing of soot, sufficient to make the surface uniformly black, was sown over the quarter.

Dahlias.—In the course of the week the tubers of Dahlias in store were looked over. Many of them give indications of growth, and in a short time a beginning will be made with propagation. This, however, will only be carried out to a limited extent during the present season, as many of the tubers will be planted out in late April just as they are.

Hardy fruit.—Owing to the comparatively mild winter the buds of Gooseberries are on the move. Where these are permanently wired in no danger is to be anticipated from the ravages of birds, but, on the other hand, owing to their being enclosed, there may be danger from sawfly. In the latter case let the bushes, as soon as they are uniformly green, be liberally dusted with soot. This will prevent the fly depositing its eggs in the tissues of the tender foliage, and if this treatment is renewed a time or two no danger from the caterpillar need be apprehended. Soot, in this case, is quite as good a preventive as is Hellebore powder, and if a little more messy it is decidedly safer. In unenclosed breaks the same practice, if followed, will prevent bud-eating birds doing damage. A damp, but not a wet, morning is best for this purpose, and care must be taken that the under sides of the leaves, as well as the surfaces, are well attended to. In these gardens, among Black Currants, "big-bud" is, fortunately, absent; but where it is known, or suspected, a sharp lookout for deformed buds is advisable. Much can be done by promptly picking off these buds, to keep the disease in check. Strawberry-beds have been lightly hoed over, in order to aerate the somewhat sodden soil, while in the course of the week some little spraying of wall trees, chiefly Pears, was attended to on suitable days.

Herbs.—If there is any necessity for sowing seeds of herbs now is the time to do so. Most of these things are easily obtained from cuttings, but from time to time it is wise to raise a few plants from seed. Seedlings, if not so quickly available, ultimately grow into strong and vigorous plants, and a change of stock is sometimes advisable. Seeds of Thyme, Sage, Marjoram, Basil, Tarragon, and so forth, if sown now will make useful plants for putting out during May.

Under glass.—The weather having been suitable for outside work, that under glass has been, during the week, limited to the ordinary routine of watering, ventilating, and firing. Seeds sown some short time ago are germinating freely, and many of them will require immediate handling. This will be undertaken during the ensuing week, and, meantime, a quantity of suitable materials has been sifted and got under cover in order that there may be no delay when a beginning is made with the pricking off, etc., which are necessary.

W. MCGUFFEOG.

Balmac Gardens, Kirkeudbright.

ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 22ND, 1916.

THE meeting held on this date was without doubt the most attractive of the present season, and, withal, the best attended. Forced bulbs were strongly in evidence, one group entirely of *Tulips* from Southgate, the other of many bulbous plants from Lady Tate, Streatham Common. Another collection of bulbous flowers from Messrs. R. H. Bath, grown in bowls in fibre, was of the educational order, and rarely, if ever, has this phase of gardening been better done. Alpines, well grown and attractively displayed, were frequent. *Primulas* of an excellent strain from Reading evidenced high-class culture, while *Orchids* and other flowers contributed not a little of both interest and variety.

FORCED BULBS.

In this section we were particularly struck with the excellence and variety of those grown in bowls of fibre and staged by Messrs. R. H. Bath, Limited, Wisbech. In all probability no similar exhibit has so fully demonstrated the value and possibilities of this interesting phase of gardening. Eminently suited to town and suburban dwellers, the exhibit also demonstrated that as high a standard of flower excellence was possible by these means as under the most skilful method of soil-cultivated examples. Variety, too, was not lacking. *Daffodils*, *Chionodoxas*, *Crocuses*, *Tulips*, and *Hyacinths* were in plenty and of the best. The rich golden Montresor *Tulip* we have never seen finer, or of a more glowing tone of colour. The handsome Leeds *Daffodil*, Crystal Queen, proved that the choicest sorts lend themselves well to this method of culture. The pretty dwarf white sort, W. P. Milner, was also good. *Hyacinths* *La Grandesse* and Grand Maitre were of exhibition excellence; *Chionodoxa sardensis* could hardly have been finer.

Messrs. R. and G. Cuthbert, Southgate, N., filled a double table with forced *Tulips* in groups, Orange Prince, Montresor, Pottebakker (white), Royal Crown, and the yellow Prince de Ligny being remarked among many sorts. The double table of forced bulbs sent by

Lady Tate, Streatham Common (gardener, Mr. W. Howe), evidenced good culture. Here *Hyacinths*, *Daffodils*, *Tulips*, and *Freesias*, among others, joined forces, and to the accompaniment of *Palms* and *Clivias* presented a very effective whole. With the *Palms* at intervals, and surrounded by the *Clivias*, the finer *Tulips* and *Daffodils* were grouped around, usually a circle of one colour. The white Joost Von Vondel *Tulip* was very fine, and not less so the bicolor *Daffodil* *Vanilla*. The groundwork was chiefly of *Hyacinths* and *Tulips* in groups, the two ends having miniature *Hyacinths* (pink and white) and *Freesias* and single and double *Campernelle Jonquils* respectively.

SHRUBS.

The exhibit of cut imported sprays of *Eucalypti* and other things set up by Messrs. R. F. Felton and Sons, Hanover-square, attracted many visitors, *Eucalyptus resinifera*, by reason of the array of reddish-scarlet buds and creamy filaments, constituting in such an exhibition a rare feature. Several other species were included, one of the more distinct being *E. longifolia*. *Grevillea angustifolia*, jagged of leaf, of silvery whiteness below and dark green above, and with reddish flower racemes, was most effective. All are highly ornamental and valuable in decoration by reason of their endurance.

Messrs. J. Cheal and Sons, Crawley, contributed sprays of *Abies* and *Picea* showing considerable variety.

Messrs. R. and G. Cuthbert, Southgate, N., filled a corner with forced *Lilacs*, of which the dark-flowered *Souvenir de Louis Spath* was one of the best. The pretty, white-flowered *Spiræa confusa* and *Staphylea colchica* were also in plenty. In a mixed group of alpines and shrubs from

Messrs. G. Jackman and Sons, Woking, *Erica carnea* was seen in good colour, the more telling plant, however, being Wood's variety of *Prunus Pissardi*, decidedly pinky in bud, the flowers more pinky than white. Of the typical kind there was also a good display.

Messrs. R. Gill and Sons brought from Falmouth a brilliant lot of early-flowering *Rhododendrons*, forms of *R. arboreum* and others. *Shilsoni* (crimson), Mrs. Henry Shilson (pink), and *Cornubia* (one of the most brilliant) were a few of the best. Yard-long sprays of *Erica lusitanica* (*E. codonodes*) showed the wealth and beauty of the Portuguese Heath at this early period in the more favoured districts.

Messrs. W. Cutbush and Sons, Highgate, N., contributed Tree *Pæonies*, *Prunus* in variety, *Magnolia Soulangeana*, and *Camellia reticulata*.

CARNATIONS.

The finest flowers of these came from Messrs. W. Wells, Limited, Merstham; better coloured examples, indeed, of *Pink Sensation* we have not seen. Informal in character, strong of stem, large of flower, and of ideal colour, a dozen or two of its flowers make an imposing stand. *Aviator* and *Champion* (crimson and brilliant scarlet respectively) are also notables in their way.

Messrs. Allwood Brothers, Haywards Heath, showed Mary Allwood very finely in a large collection of the best. Terrific, a pink-flowered perpetual *Malmaison* sort, a pioneer in the new race calculated presently to displace the older types of *Malmaisons*, is full of promise.

Messrs. Cutbush also showed one of these perpetual *Malmaisons* in the rich scarlet *Sabina*, a novelty of the moment quite equal to the largest *Malmaison* we know. *Lady Jugestre* (exquisite salmon-pink) was very good.

GREENHOUSE PLANTS.

The extensive table of *Primula sinensis* from

Messrs. Sutton and Sons, Reading, was a feature, circular basket groups, to colour of the best, being arranged interspersed by a groundwork of other distinct sorts. One of the more conspicuous was the still indispensable *Duchess*, one of the greatest gains to the fancy section of these flowers. *Prince of Wales* is a new, intensely coloured crimson, with deeper crimson eye. *Terra-cotta*, *Crimson*, *White*, and *Pink* are of the *Giant* set, while *Giant* mixed afforded a good idea of the excellence of this strain.

Messrs. H. B. May and Sons, Limited, Edmonton, staged a fine array of *Cyclamens*, in several shades of colour, representative of the *Giant* strain throughout. *Columnea magnifica* was noted in the group with *Davallia Lorrainei*, *Osmunda palustris undulata*, *Gymnogramma schizophylla superba*, and other ferns.

Mr. Elisha Hicks, Twyford, exhibited the climbing form of *Lady Hillingdon Rose*, together with a batch of the single crimson *Princess Mary*. Obviously both force well. Large-flowered *Cinerarias* in variety, and of excellent strain, came from

Messrs. Camell and Sons, Eynsford, Kent, the blue and crimson shades being very striking.

Messrs. Robert Veitch and Sons, Exeter, staged the new red *Cineraria Matador*,

which gained an Award of Merit. The shade of colour is novel and distinct.

Messrs. Stuart Low and Co., Enfield, contributed Epacris and a variety of Acacias not usually met with to-day.

Messrs. J. Carter and Co., Raynes Park, contributed largely of their new *Primula malacoides* King Albert, which gained an Award of Merit. On the occasion of the last meeting the variety was unwittingly presented for certificate as "Rose Queen." That name having been already appropriated for a *malacoides* *Primula*, no second award could be made, despite the fact that the newcomer was recognised as distinct and a great advance. As King Albert it gained, as it also merited, the Award of Merit by a unanimous vote.

Mr. L. R. Russell, Richmond, filled a table with Indian Azaleas, which afforded a mass of rich and varied colours.

HARDY FLOWERS AND ALPINES.

Messrs. Cutbush and Son, Highgate, N., showed many alpiners, notable being *Saxifraga Stracheyi*, *Adonis amurensis*, fl. pl., *Soldanella alpina*, and *Tulipa Kaufmanniana*, the bulbous *Iris Krelagci* and *Hepaticas* being also good.

Messrs. George Jackman and Sons had good examples of *Iris stylosa* (*unguicularis*), Lenten Roses, many choice *Saxifragas*, and their new multipetala variety of *Cyclamen Coum*.

Messrs. Waterer, Sons, and Crisp, Twyford and Bagshot, showed the choicer *Saxifragas* well on a bank of rockwork. The true Cherry Trees (yellow) was excellent, likewise the inimitable Faldonside. *Oppositifolia* forms, *alba*, *pallida*, *pyrenaica*, major, and the type were strongly in evidence.

Messrs. Tucker and Sons, Oxford, had some of the choicer alpiners. Among *Saxifragas* we noted the pretty primrose-yellow *S. Rocheliana lutea*, delicate of colour. *S. Obristi* is among the largest of pure whites. *Stuarti*, *Griesbachi*, *thesalica*, and others represented the red-flowered set. *S. dalmatica* is a good white, not far—if at all—removed from some of the forms of *S. scardica*.

Messrs. Whitelegge and Page, Chislehurst, showed fine groups of *Saxifraga apiculata*, *S. Elizabethæ*, *S. oppositifolia alba*, and others. We thought *Pulmonaria angustifolia azurea* one of the best bits of blue among early hardy flowers.

Mr. M. Prichard, Christchurch, had a well-flowered specimen plant of *Saxifraga Burseriana Gloria*. *S. B. tridentina* was also good. *Apiculata*, L. G. Godseff, *Paulinæ*, Faldonside, *Elizabethæ* (all yellow-flowered sorts) were in generous and telling groups.

Mr. G. Reuthe, Keston, had the rare and choice *Saxifraga ochroleuca*, a distinct yellow. *S. Boydi* and *S. Faldonside* were full of yellow blossoms, and no two yellows equal them. *S. Borisi* is also yellow and of goodly habit. *S. apiculata alba* was very finely presented. The gems of the group, however, were the inimitable *Shortia uniflora grandiflora* and the equally unique *Crocus aeriis*, a Grecian species whose deep violet-blue petals, with paler interior, defy description.

Messrs. Barr and Sons had pretty colonies of *Narcissus minimus*. Such *Saxifragas* as *Mrs. Leng* (yellow), *S. oppositifolia magnifica*, and *S. Burseriana magnifica* were well shown. *Iris unguicularis* and *I. tingitana* were among unusual things.

Messrs. T. S. Ware, Limited, Feltham, showed well of Lenten Roses, *Morisia*, *Polygala Chamebuxus*, *Saxifraga Faldonside*, *Anemone blanda*, and other early flowers.

ORCHIDS.

Messrs. Charlesworth and Co., Haywards Heath, showed the remarkable *Odontioda Dora*, which gained an Award of Merit. It is a dark, richly-coloured form.

Messrs. J. and A. MacBean, Cooksbridge, showed the lovely white-flowered *Cattleya Cowanæ alba*, together with a variety of *Cymbidiums* and *Odontoglossums*.

Messrs. J. Cypher and Sons, Cheltenham, had many choice *Cypripediums*, notably *Beckmanianum*, *C. Victor Hugo*, *C. Maudie*, and *C. Helen II*. *Dendrobium nobile virginale*, full of pure white blossoms, was very beautiful. *D. Ainsworthi intertextum*, with white and crimson flowers, was also fine.

Messrs. Armstrong and Brown, Tunbridge Wells, showed the new *Lælio-Cattleya Erzerum*, satin rose sepals and purplish crimson lip. *L. C. Myra* (yellow and crimson) and the white *Dendrobium nobile virginale* were also noted.

Messrs. Stuart Low and Co. had well-flowered examples of *Vanda Amesiana* and the white-flowered *Dendrobium Jamesianum*.

FRUIT.

Messrs. Cannell and Sons, Eynsford, showed forty-two varieties of Apples. The central basket of Newton Wonder was perfection, every fruit of model character. Wellington was in the nature of a revelation. Little known—albeit excellent—sorts were here too, and of these we selected Stayman's Winesop, Calville Malingre, a fine late sort, and Rymer. Betty Geeson, Lord Derby, Northern Spy, Alfriston, Nancy Jackson, and the yellow-skinned Atalanta were also good.

A complete list of the plants certificated and medals awarded will be found in our advertisement columns.

CORRESPONDENCE.

PLANTS AND FLOWERS.

***Polygonum baldschuanicum* (A. H. Maude).**—This is practically a deciduous climber, which in severe weather may be cut to the ground to break away freely in the spring. In mild winters the twining stems retain their vitality and send forth fresh growths in spring from axillary buds along the stem. The beauty of the plant is enhanced when allowed to grow naturally through the branches of some tall tree, as may be seen in its flowering season in the Royal Gardens, Kew.

***Clematis Flammula*, pruning (A. H. Maude).**—As this blooms on the wood of the current year, the best way is to prune after the flowering season is over—say in November. It may then be cut hard back, and it will in the following spring make vigorous growth. If allowed to remain unpruned for several years it forms a dense mass of tangled shoots that spoil the naturally graceful appearance of the plant. When sending queries in future, please write on one side of the paper only, and let each query be on a separate sheet.

***Odontoglossum Lindleyanum* (Netherton).**—The name of your Orchid is *O. Lindleyanum*, and that it should flower among a batch of *O. luteo-purpureum* is nothing unusual, as the two species grow together in the district around Bogota. If you purchased the plants as newly-imported or unflowered in this country, even a firm of standing could not ascertain whether the whole would be absolutely true to name, but if approached they would in all probability exchange them. In these days *O. Lindleyanum* is of but little value.

Good single *Chrysanthemums* (Memorial).—There are many fine, large-flowered single *Chrysanthemums* well suited for the purpose you name. The following are consistently good and can hardly be regarded as novelties: Four beautiful singles of the largest size are *Sussex Yellow* (a golden-yellow of splendid quality), *Jessica* (a reddish-bronze flower having golden tips to the florets, and a flower of beautifully even form), *Molly Godfrey* (a good variety, the colour of the blooms being deep pink with a white zone round the disc), and *Portia* (a large and handsome rich bronzed flower of splendid quality). *Sandown Radiance* when well grown is one of the most beautiful and striking singles. The colour is rich chestnut-crimson, and no collection can be considered complete without it. *Bertha Fairs*

is somewhat new, but it is such a fine single that it should be included in your selection. The colour is orange flushed rose, and the form is superb. *Isobel Felton* is a very large light golden-yellow sort of high quality; and *Junno*, a 7-inch flower of a rosy-lilac colour with silvery zone. We would advise you to allow your plants to break naturally, retaining buds that develop towards the end of August or early September.

The Winter Sweet (*Chimonanthus fragrans*) not blooming (A. H. Maude).—You say nothing as to whether you prune your plant or not. If you do prune, it is possible that you do this at the wrong season. Seeing that the flowers are borne on the previous year's growth, pruning should always be done after the plant has flowered. Then the shoots that have bloomed should be cut back to the main branches, and when growth again starts shoots that will flower the following season will be plentiful. These, again, should be pruned in the same way as those that preceded them. A few twigs in bloom last a long time. No harm is done by cutting away these twigs, as they would be cut away after the flowers have faded.

TREES AND SHRUBS.

Pruning shrubs (A.).—No general rule can be given for pruning all kinds of shrubs, as the operation should vary according to the habit of growth and flowering of each kind. Some kinds bear flowers on the current season's growth, others upon the shoots made the preceding season, and as the object of pruning is to encourage plentiful bloom, the aim of the pruner should be to cut away all growth that appears to be useless in the formation of new wood which will bear flowers. If the bush is very much crowded with shoots, the worst of these should be cut away, so as to give the bush a better chance of producing vigorous growth and ripening it. You had better defer pruning till next season, and in the meantime observe carefully the varying modes of flowering among shrubs, and by next pruning time you will be able to judge for yourself as to the proper way to prune. The principles of the operation of pruning are those given above.

FRUIT.

Protecting Pear blossom (A. H. Maude).—No; if you can, try and protect the blooms. If the trees are on walls protection is easily given by fixing some Bamboo canes to the coping with the other end of the canes in the ground, and on these stretching two or three thicknesses of fishing-net.

VEGETABLES.

Cabbages clubbing (Maeking).—The best remedy for clubbing is gas-lime. That should be applied to vacant ground in the autumn at the rate of 2 bushels to 3 rods if clubbing is very bad. If it be not, then put 1 bushel on 2 rods of ground. After lying on the ground from four to six weeks, dig the dressing in. On the ground which has been dressed with the gas-lime do not plant any of the Cabbage tribe. Plant Potatoes, Seakale, or Rhubarb, or sow Onions, Parsnips, or Beet. By doing so for a couple of years the club trouble may disappear. Peas or Beans also may be sown with advantage. Of course, you must understand that ground dressed with gas-lime cannot be cropped for three months after the dressing has been applied.

MISCELLANEOUS.

Millipedes (A Twenty Years' Subscriber).—The insects you send are millipedes. They are very destructive to the roots of plants, and can only be destroyed by using one of the soil fumigants of which there are now several on the market. We have seldom seen such poor soil as that you send. What it wants is an addition of some loamy soil and a heavy dressing of cow-manure. In soil such as that you send *Violas* will do no good unless you have it thoroughly well manured. There is no body in it whatever.

Leaf-mould (T. D. Lawson).—The best of all leaf-soil is that from decayed Oak leaves, as these seem to be more of a woody nature than are larger leaves. Gardeners, however, collect all leaves irrespective of the trees which produce them for the making of leaf-soil, and so long as they are thoroughly rotted we can see that no harm can follow the use of whatever leaves can be had. Leaves ought to lie for one year before they are used, and in the meantime they should be freely turned, and, if need be, wetted, in order to hasten decomposition. A little lime mixed with them is also very beneficial.

Acetylene gas refuse (Oak, Prestbury).—From an analysis of the residue from acetylene gas it has been found that the value of this product is entirely due to the lime it contains, other plant foods, as nitrogen, potash, and phosphates, being absent. The lime is present either as slacked lime in fresh samples, or carbonate of lime (mild lime) in samples which have been exposed to the air. It should prove an effective and cheap dressing for all purposes for which lime is recommended, and should be of special value on soils which are sour, or deficient of lime, or inclined to be stiff, and as a top-dressing for pasture.

NOTES OF THE WEEK.

The Cherry Plum in the house.—I have branches of the purple Cherry Plum and Forsythia in the house picked more than a week ago—before the snow—now a sheet of blossom. The Prunus is really lovely, with its white buds and flowers, and little brown leaves just showing.—E. V. P. D.

Mezereums have been this year, particularly the white, a sheet of blossom, and there are two distinct shades of the mauvy-pink ones, all grown from seed. It is sad they take so many years to grow to a good size, but when they arrive at that they are, indeed, beautiful and sweet beyond words.—E. V. PORTMAN DALTON.

Narcissus minimus.—The earliest flowers of this were noticed fully expanded on February 22nd. This is earlier than usual, although at Gatehouse-of-Fleet, some ten miles distant, *N. minimus* was in bloom on the 2nd of the month. Gatehouse is, however, in an exceptionally favoured position.—W. McG., *Balmac, Kirkcubright*.

—This Daffodil has been in bloom for the past two or three weeks. A small group nestling at the foot of a large Elm, where the morning sunshine plays among the flowers, is very pretty, the rich yellow flowers, each scarcely $\frac{3}{4}$ inch across, borne on slender rush-like stems about 5 inches high. It is naturalised in the Grass, and is annually one of the heralds of spring, preceded only in earliness by *N. pallidus præcox*. Both of these should be grown by everyone fond of choice early flowers.—E. M.

Overdoing wild gardening.—The good of this plan is now admitted, and it is practised with success in many places. The danger is in overdoing. In *Country Life* for February 26th there are two views showing Crocuses as thick as the Grass in which they grow. In this way all relief and grace are lost. One-tenth of the number would give a far more pleasing effect.—W.

The dwarf Almond (*Prunus (Amygdalus) nana*) is all too little grown in gardens where early flowers are enjoyed. A bush 2 feet to 3 feet high wreathed with its pink or white flowers on the leafless branches is a source of great delight in the spring. The fully-developed flowers may suffer from frost, but there are generally others to follow, and the little bush is soon as bright as ever.—S. A.

Retirement of Mr. T. Challis.—Mr. T. Challis, for many years gardener at Wilton, has retired, after a long and very active life, fifty-five years of which he spent under four Earls of Pembroke. He now lives in a charming place on the estate with a good garden attached to it, where we all wish him many happy years. Under Mr. Challis, Wilton was as famed for its good gardening as for the beauty of the views in the home landscape.—W.

Humogen—Summary and conclusions of report at Wisley.—Bacterised peat is a preparation of bog Moss acted upon by certain bacteria, and subsequently used as a culture medium for the development of nitrogen-fixing bacteria. The *exact details of its manufacture are not divulged. On this account most of the experiments possible with it are of an empirical nature.* (The italics are ours.) [This must be described as working in the dark.—Ed.]

Primula nivalis in pots.—A native of the Caucasus, the Snowy Primrose is quite hardy. I have seen it thriving luxuriantly as a border plant in central Aberdeenshire, where the thermometer often falls below zero. On the other hand, I have seen it fail in a comparatively mild district, the cause being the lack of proper drainage. This Primula does well in pots, making a brave show during February or March. Five-inch pots are large enough.—ALBION.

The flowering of the Daffodils.—My first Daffodil to flower this year has been *Narcissus pallidus præcox*, which is sheltered beneath a bush of *Spiraea canescens*. It was first observed fully open on February 13th. A day or two afterwards the first flower of *N. minimus* opened. The Saragossa Daffodil, which is usually the earliest here, is not yet open to-day (February 21st). *N. cyclamineus* is considerably later than usual this year.—DUMFRIES.

Crocus *aerius*.—This rare and very beautiful Grecian species gained an Award of Merit at the Royal Horticultural Society's show on February 22nd by a unanimous vote. The predominant colour-shade is deep violet-blue, lighter on the inner segments of the perianth and whiter at their bases internally. The tube portion is golden, the moderately large stigmata of orange-red tone. Although beautiful and unlike any other species, it is quite a gem among the winter-flowering Croci, attracting not only by reason of

colour combination, but also because of its rounded, well-set-up flowers. For alpine house, or frame, where all its unsullied charm would be revealed, it should prove ideal, also, when a stock has been got together, for a sunny, sheltered spot in the rock garden.—E. H. JENKINS.

Viburnum macrocephalum.—Besides the somewhat tender constitution of this fine shrub there is another reason which your correspondent (page 113) does not mention for its scarcity in British gardens. It is usually supplied as a plant grafted on a stock of *Viburnum Lantana* or some other common species. The stock sends up growth at the expense of the scion, and unless this is detected, the choicer species soon disappears. The same mischief lies in wait for the most beautiful of all the *Viburnums*—*V. Carlesi*.—HERBERT MAXWELL, *Monreith*.

Callicarpa purpurea.—This is a very desirable plant for the stove or warm greenhouse, its bright purple berries, freely borne along the long stems, being very effective during the dull days of winter and lasting a long time. Where a moderately high wall is available it is very suitable for clothing it with. It is easily propagated from cuttings in spring, and will make nice plants in 6-inch pots the first season. It can be grown on for several years, larger pots being used. It must be cut close back in early spring.—ALBION.

Apple Bramley's.—I am sending you specimens of Apple Bramley's, just picked from the heap. It is excellent for baking, not bad to eat, and quite the best Apple we have here, as it never fails to bear a crop on standard trees. The tree is very attractive in form, too, so branching and spreading. Do you know Ellison's Orange, a local seedling found in the Rev. C. Ellison's wonderful fruit garden, and thought much of here? On this soil it is a better doer and cropper than Cox's Orange.—G. E. PORTMAN DALTON, *Fillingham Castle, Lincoln*.

Early flowers.—Mr. Arnott having referred to the date at which *Anemone Hepatica* (page 93) and *Iris reticulata* (page 106) usually flower in the north-west, it may interest him to have my notes upon recent years. *Anemone Hepatica*, January 20, 1906; February 2, 1908; January 2, 1909; January 21, 1910 (single red); January 13, 1911 (white and red); January 26, 1913; January 20 (white), February 4 (red), 1916. *Hepaticas* do not luxuriate with me; that is, they do

not increase fast, and there are no seedlings. The most profuse growth of them which I ever saw is in Lord Stratheden's garden at Hartrigg, on Tweedside. There they cover as much of the ground as they are allowed to do—a beautiful sight. Of *Iris reticulata* I have the following dates of flowering:—February 15, 1908; February 19, 1909; February 20, 1910; February 19, 1912; February 15, 1913; February 28, 1915; February 18, 1916.—HERBERT MAXWELL, *Monreith*.

An early-flowering Almond (*Prunus Amygdalus*, var. *præcox*).—In the South of England, particularly in the suburbs of London, the Almond is one of the most popular of all early-flowering trees, and it can be relied upon to bloom freely every year once it has become well established. The majority of the trees grown, however, are of one kind, all blossoming at the same time, although there are several varieties which differ in the colour of the flowers, their size, and the time they open. Of these varieties the one under notice is specially worthy of attention, for it blossoms several weeks in advance of the type or other varieties. This year it was well in bloom during the first week of February. Occasionally the blooms open in January, but the normal time is late February or early March, and they are often about to fall or quite over by the time the flowers of the type expand. Its usefulness in the garden will be readily appreciated, for any tree or shrub blossoming before mid-March is worthy of encouragement. It is as free-flowering as the common Almond, the colour being the same.—D.

Carnation Pink Sensation.—Messrs. W. Wells, Limited, Merstham, who appear to have excelled in the cultivation of this handsome American variety since it first reached these shores, had the best coloured blooms of it I have seen at the Royal Horticultural meeting on February 22nd. There was nothing to equal them in this respect or for size in the entire exhibition. Of a superior type of excellence in many ways, particularly in regard to the easily-disposed petals, their large, uniform size to near the centre of the bloom—ever a strong point in a high-class flower—and the rosette-like formation of the bloom as a whole, it is a variety which appeals forcibly at a glance. Easily the largest of the American class—4-inch large blossoms are not uncommon—and characterised by broad, flaky, roundly-notched petals, it is distinct from all. Size alone, however, would have but little weight with anyone qualified to judge of the merits of a variety, but when to this, colour, good form, and not a little refinement are wedded, we have some of the things that matter and which go to make a Carnation popular. Did it but possess fragrance it would be ideal. Its strength of stem is remarkable.—E. H. JENKINS.

The Dwarf Russian Almond (*Prunus nana*).—This is a miniature Almond in all its parts, for leaves, flowers, and fruits resemble those of the common Almond in all respects except size. It is found wild in Russia, its native habitat being S. Russia and other parts of S.E. Europe. It forms a bush, suckering freely from the roots. The bright rose flowers are each about 3 inch across, borne from the axillary buds of the previous year's shoots. Several forms have been given varietal names. Of these, *alba* has white flowers, and *georgica* and *Gessleriana* have more richly coloured blooms than the type. *P. nana* should be given a sunny position in good loamy soil. It can be increased by detaching suckers, but if such are not available then the lower branches should be layered, for cuttings are very difficult

to root and the fruits rarely ripen in this country. A position near the front of a shrubbery suits it admirably, or it may be planted in a small group on the margin of the lawn.—D.

The purple Cherry Plum.—This is usually called *Prunus Pissardi*. Like all the world I took to it, but never succeeded with it, owing to the birds, which took out all the flower-buds. This may have been only one cause. I think it loves warmer ground than mine. I planted the ordinary trade form, which is grafted on the wild form. Some years ago I planted some from seed which I got abroad. I heard that the tree came true from seed, and so planted some trees in a shrubbery. I notice now they flower more freely than the others. To me it is one of the most charming things we can have in the house—buds and blossoms—at this season. It is a simple purplish form of the old Cherry Plum, long known in England. The common form has been largely advertised as a fence plant, for which it is useless and not nearly so good as our own Quick.—W.

Cydonia japonica, var. *cardinalis*.—The various forms of the Japanese Quince are amongst the most beautiful of early-blooming shrubs; moreover, they have a very long-flowering season, for they are often in bloom soon after Christmas, and blossoms continue to open until late spring. The varieties show a great range of colour, for there are many shades of red, pink, white, and a combination of pink and white. The most beautiful are those with dark-red flowers, and of these *C. j. cardinalis* is perhaps the best, for it blooms freely, and the flowers are each from 1½ inch to 2 inches across. There is, however, another variety which runs it close for first place, that being *sinica*, which has semi-double flowers of a rich crimson hue. Although these kinds can be grown as bushes in the open ground, they flower much earlier when planted against a south or west wall. During the present year plants have been blossoming freely ever since the New Year, and are still in good condition. The better varieties can be increased by cuttings or by layers, the latter being the better method.—D.

Bulbs among border Carnations.—Where Carnations are allowed to remain undisturbed for several years the Turk's Cap Lily (*L. Martagon*) or Narcissi can be successfully grown with the Carnations. The leafage of the Carnations affords that slight shade to the Lily bulbs they so much appreciate, and has no ill-effect on the Narcissi. The planting of both layers and bulbs may be done in early autumn or spring—the former for preference. If, when the Carnation plants are worn out, the bulbs should be still doing well, leave them where they are and replant the site with *Violas* or dwarf annuals. If preferred, the bulbs can be lifted and replanted where the fresh Carnation bed is to be. From the second year it will be found advantageous to both bulbs and Carnations to give a slight top-dressing of old sifted manure and leaf-mould, or burnt refuse and decayed manure. A somewhat similar practice was followed by the late Dean Hole. The Dean's plan was to plant Carnations and Narcissi in alternate rows, so that when the latter were over they were soon followed by a display of Carnations. The system advocated in this note is to plant a Carnation bed or group in the usual way and then plant some bulbs between the Carnations. This plan, of course, is advocated only from a decorative point of view, and would be of no use to those who grow for exhibition.—C. TURNER.

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

SUMMER ANNUALS IN THE FLOWER GARDEN.

If it is a fact that alike in the majority of public and private gardens there is to be little or no attempt at summer bedding, those whose flower gardens are already well stocked with Roses and a representative collection of hardy plants will have reason to congratulate themselves, otherwise the beds will have to remain bare and untenanted unless they are filled with annuals. There is, fortunately, a goodly number of these available, but if one has to rely on them almost entirely for the summer display it is necessary to make a careful selection alike of the most enduring, the most suitable respectively for large and small beds, variety of colour, different shades in the particular colours, and other matters. There are some annuals possibly more brilliant than anything else one can plant, but which, unfortunately, are only short lived, like some of the *Viscarias*, as *cardinalis* and *fulgens*. The best and most enduring annuals for small beds in different colours would be *Linum grandiflorum* (scarlet), *Marigold Legion of Honour* (chocolate and yellow), the latter shade predominating, *Nemesia Blue Gem*, and *Petunia Rosy Morn*; or if a dwarfier rose was required a *Tufted Pansy* of the shade and habit of *William Niel*. The flat appearance of such beds can be relieved by one or more plants, as may be required, of *Grevillea robusta* or *Eucalyptus cordata*, and a very charming effect is produced with the light, graceful foliage of the taller things. About a dozen of each of the dot plants will be sufficient for quite a considerable area, and the little extra trouble in raising and growing them on will receive compensation in the general effect produced. In taller flowers the scarlet-purple and rose shades will probably be best represented by *Antirrhinum*, *Clarkias*, and *Pentstemons*, and of the three I prefer the last named, for they combine rich colour with endurance and a light, graceful appearance. When treated as annuals it is advisable, if distinct colours are required, to sow seed of a good strain. Not much trouble or labour is required to keep over in a cold frame sufficient to plant two, or more, beds. Representatives of the colours above-named to guide in the selection of seedlings are *Southgate Gem*, *Paul Cambon*, and *Louis Grandeau*. If the planter is content with beds of mixed colours the seed can be sown in February.

Yellow, or rather its many shades, from deep orange to primrose, might be used for one or more large beds, and is easily obtained. A pleasing arrangement is to mark out a few irregular groups and put in a few seeds of the *Canary Creeper*. These can be enclosed with twiggy *Pea* boughs not too symmetrical in outline, and the remainder of the bed filled in with dwarf *Nasturtiums*, either in one shade or several, according to taste. Careful selection and seed saving will give in time a splendid variety of rich and soft colours. If a regular, somewhat flat, surface in yellow is not objected to it can be supplied respectively in tall and dwarf annuals by *Calendula Orange King* and *Tagetes pumila Golden Gem*. In brilliant rose and pure white we have *Lavatera splendens* growing well over 30 inches in good soil, and making, either individually or mixed, a pleasing and enduring display; indeed, when one notes the delicate nature of the petals, the endurance of the flowers, either in the open or in a cut

state, is remarkable. Another very enduring annual, noteworthy, perhaps, for individual beauty of flower rather than the striking display made in the beds, is *Salpiglossis*, a new dwarf strain of which is decidedly attractive, producing a great variety of different shades. E. B. S. Hardwick.

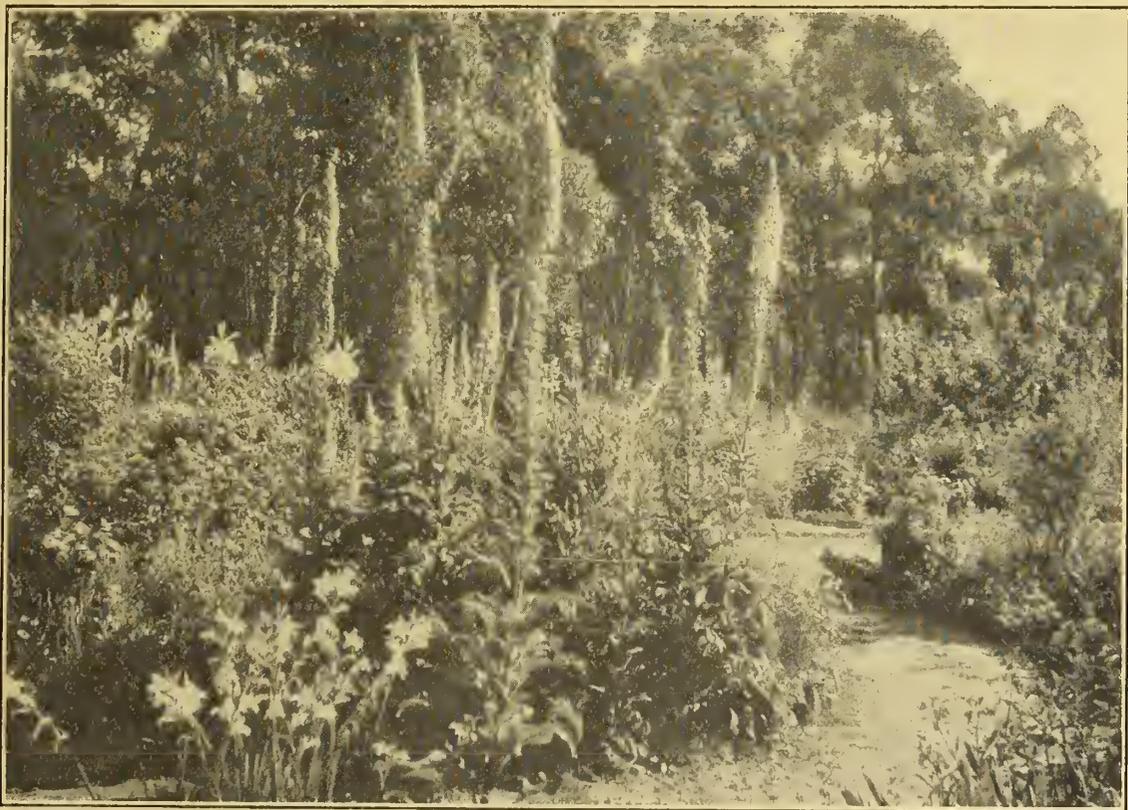

AUSTRALIAN NOTES.

It has taken the people of Australia close on a century to realise the vast decorative possibilities of Australian vegetation. Other folk, then, may well be forgiven their ignorance of the fact that Australia in her flowering trees and shrubs possesses a wealth of beauty calculated to give any garden-lover pause. In Victoria alone, a few miles from the heart of the capital, starry Ti-tree (*Leptospermum scoparium*) blossom, fragrant Wattle, royal purple Sarsaparilla, and creamy Clematis blossom are present in such abundance that the visitor is apt to overlook the

No one who has seen these Wattles in bloom, almost meeting 20 feet above a creek, covering the water below with golden pollen, or overhanging some wide river is ever likely to forget them. The blossom appears to gather up the sunshine of early spring till the trees actually vibrate with colour. So dense is the blossom in good seasons that one may thrust an arm amongst it and, with the shoulder pressing into the fragrant mass, the finger-tips may not have entirely fathomed it. The trees are singularly shapely, and, though somewhat short-lived, make lawn trees of exceptional beauty. In Australia, where Wattle-bark is used largely in the tanneries, big tracts of Wattle-tree are grown solely for utilitarian purposes. Bee-keepers also regard the Wattle family with very friendly eyes, and the farmer is the exception who does not have a group of one kind or another about his homestead. Very few trees will thrive on so many different soils or in

its most forcible appeal. As an individual tree the quaint, almost grotesque lines of its rough trunk are delightful, while its crest, affording a most excellent shade, somewhat suggests the Cedar of Lebanon with its horizontal foliage. The tree realises its greatest glory very shortly after midwinter, when it blossoms with an abandon characteristic of no tree subjected to the climatic wear and tear that the Ti-tree gets in its native habitat. The blossom resembles Hawthorn, though it is considerably larger. The method of propagating Ti-tree is interesting and unusual. When the trees are in full bloom branches are cut off and dried for a week or two. They are then burned and the ashes spread over the soil. The burning liberates last year's seed, and this seed comes up readily in the ashes of this year's foliage.

In praise of the Gum-trees (*Eucalyptus*) known specially as flowering Gum-trees there is a vast amount to be said. The

Foxgloves in an Australian garden, with the bush beyond. From a photograph sent by Mrs. C. Walker, Wombolano, Ringwood, Victoria, Australia.

claims of scores of less important though equally beautiful flowers.

One of the chief characteristics of these Australian trees and shrubs is their extreme adaptability. Australia itself presents an immense diversity of climate, and the fact that the various Gum-trees, Wattles, and Ti-tree have been successfully established from end to end of this Continent indicates the possibility of their thriving equally well in almost any country of the world. The Wattle, practically adopted as the national flower of Australia, usually has first claim on gardeners. The varieties of Wattle seem endless, and though few gardens of any note fail to show the Cootamundra (N.S.W.) Wattle, either singly or in groups, or the magnificent Golden Wattle that comes originally from the mountains, the equally beautiful Silver Wattle and the Black Wattle are rarely cultivated seriously. Both these latter varieties denote watercourses, though both will thrive away from water.

such varied climates, and, given the necessary shelter, they are particularly happy in the southern counties of England.

Another tree with great decorative possibilities is the

TI-TREE (*Leptospermum scoparium*). As a hedge plant it has few rivals. No drought is so intense but what the Ti-tree will retain its greenness through the very worst of it. No weather is too cold, too dry, too wet, or too rough for it. It quickly forms a shelter of the most perfect kind, and in several of the small coastal towns a Ti-tree hedge is grown round public school gardens before the children start the little ornamental and utilitarian plots in connection with which most Australian school-children are taught the elements of horticulture. The pleasure-gardens in exposed places are also frequently given the benefit of a Ti-tree hedge, and no gales are ever strong enough to damage it. It is not, however, as a hedge plant that the Ti-tree makes

trees have large, tough, dark green, oblong leaves, showing, after the fashion of all the *Eucalyptus* family, a great deal of red in the younger stems and leaves. The trees are beautiful from the first, and attain a growth of from 30 feet to 50 feet in a few years. The flowers, each of which is about as large as a Walnut, grow in great clusters. They are of the same fluffly nature as Myrtle blossom, with an infinity of thread-like petals, and very beautiful. They vary greatly in colour—flame-red, rose-red, pink, deep cream, and a greenish-white being among the most familiar kinds. They have found their way into the majority of suburban gardens in Australia, and their gorgeous blossom often gives the only distinction to a quite common-place thoroughfare. Like most Australian trees they are, however, frequently to be found living in perfect harmony with flowers and trees from other lands. HENRIETTA C. WALKER.

Victoria, Australia.

NOTES AND REPLIES.

Antholyza crocosmioides.—I have a very large clump of *Antholyza crocosmioides* which has not been disturbed for many years. There are quantities of flowers, and I think last autumn they were even better than usual. I have been taking up a good many tubers lately for my friends, and am surprised to see what an enormous quantity there are—five or six all joined together. Can you tell me whether these tubers should be pulled to pieces and only the top one replanted?—E. CHARLES BUXTON, *Coed Derw, Bettws-y-Coed.*

[While we are inclined to regard the chain-like arrangement of tubers as in the nature of reservoirs—not so much in British gardens, perhaps, as in the native country of the plant—it is fairly clear that that most recently formed is the most important. For preference we should retain two, though the commercial grower often sends but the one. Some South African terrestrial Orchids have the same chain-like formation of underground tubers. Receiving a batch a few years ago we planted some intact and divided others, but only the former flowered the following year. Hence, we concluded the removal of the others constituted a check.]

Border Carnations.—With a view to reducing labour as regards watering, etc., anything that can with safety be planted out now will be dealt with. The above-named, which have been well hardened off, will be planted in a long border prepared for them some weeks ago. Carnations need an occasional change of soil and site. The border mentioned is situated in quite another part of the garden. The plants will be set out in groups, each group containing three plants of each particular variety, the groups being 18 inches apart each way. To prevent sparrows despoiling the plants by cropping down the young, tender leaves on the point growths, the border will for a time be netted.—A. W.

The Carpathian Snowflake (*Leucojum vernum carpathicum*).—Is not Mr. Markham (page 82) referring to *L. vernum*, var. *Vagneri*? According to Mr. J. G. Baker, who refers to the *Botanical Magazine*, *Erinosma* (now *Leucojum*) *carpathicum* of Herbert, "is a form with the perianth segments tipped with yellow instead of green." *L. Vagneri* is the tall, robust variety, which generally produces two flowers to a stem, blooms earlier, and has very fine, deep green spots. *L. v. Vagneri* is often sold for *L. v. carpathicum*, which is later than the other. *L. v. carpathicum* is not yet (February 9) in flower, although *L. v. Vagneri* has been in bloom for about a month.—S. ARNOTT.

Aster Thomsoni.—This beautiful *Aster* is frequently lost in the process of propagation. The following advice, given me a number of years ago by a successful amateur, has been so useful that I reproduce it for the benefit of other growers:—"If you want to increase it, take it up just as it begins to shoot in spring, and cut it up. I generally select three or four crowns, start them in moderate warmth, harden off, and then plant out. If you try to divide it as the ordinary Michaelmas Daisies, you will lose it." Still another method is to lift the plants in autumn, divide them, pot the pieces, and keep them in a frame all winter.—S. ARNOTT.

Dahlias.—The tubers have now been placed in heat in order that shoots may be produced for propagation. These, slipped off with a heel, or, better still, taken with a small piece of the parent tuber adhering, if kept close in a warm house soon root. The various sorts of Dahlias required, if packed closely, with a little leaf-mould, in spare window-boxes and placed upon hot-water pipes, will soon furnish plenty of good cuttings. This method, if a little rough-and-ready, will be found to answer admirably, and space, always a consideration in spring, is economised.

Gladioli.—As these are useful over a long period, the first batch has been boxed-off and placed in a greenhouse, followed by a second lot put in about three weeks after. In addition, large quantities are planted in a dormant state, at intervals, in the open, and by this means a succession of spikes is secured almost until the end of the season. Those planted dormant are put fairly well down—as, indeed, are those started in boxes—this helping to steady the foliage until stakes can be given.

Crocus Imperati.—I am glad to see, in GARDENING ILLUSTRATED of February 26th (page 111), that Mr. Cornhill praises this *Crocus*. It is early, the flowers have more substance than those of several of the others, and are thus better able to withstand the rigors of the earliest months. It is pretty even in the bud state.—S. ARNOTT.

GARDEN FOOD.

NOTES AND REPLIES.

The Celery Cabbage.—The *Celery Cabbage* is a new vegetable introduced into this country from China. It supplies a long-felt want—a vegetable which can be eaten either cooked or raw, and is quite equal to boiled Spinach. It is also first-rate as a salad, or for sandwiches or soup. The plant is a very rapid grower, and is fit to be cut in eight weeks from the time of sowing, and would be splendid for *cloche* work or in a cool frame. Salad could be grown all the winter. It grows to about the size of a *Cos Lettuce*, having the same upright growth, and it has a white midrib, which is excellent when boiled. Seed should be sown in early spring and autumn in rows 15 inches apart, and it should be thinned out to 9 inches between each plant. In the hot season the plant is liable to run to seed. In Canada it is used for cold slaw, which is made as follows:—Cut the *Celery Cabbage* in half and lay in cold water, then shave it very fine; boil from half to a pint of vinegar, stir into it the well-beaten yolk of an egg, and then pour it over the *Cabbage*, and serve with cold meat.

[Can any reader tell us anything of this?—Ed.]

Food in the garden.—The most important crops are Potatoes and other roots usually termed tap-rooted. The land for the latter should be thoroughly aerated by exposure, but no fresh manure applied. Early Horn Carrots may be sown in shallow drills in February and again in March or April. The small early Horn Carrots do not require much thinning, as they are fit for use when quite small, and, by drawing the largest for use, the smallest will continue to grow. A small bed of the early Horn Carrot will produce many dishes. Parsnips, if large roots are wanted, may be sown early in March, but if flavour is considered, delay sowing till April, or even the beginning of May. Beet transplants well, so seeds for early roots of the Turnip-rooted variety may be sown in boxes under glass and transplanted to a suitable position outside when well hardened off. From this time onwards Peas and Beans may be sown as required in succession, fortnightly or otherwise. Cabbages may be transplanted at any time during spring and summer so as to have a regular succession. Brussels Sprouts are sown in boxes under glass in February, and outside for later planting in April. Spinach can be sown as a catch crop between rows of Peas or wherever land is vacant. Those who are often brought into contact with amateurs or allotment-holders know that more attention is given now to easily-grown food products than formerly, and the matter is worth consideration.—E. H.

Cape Broccoli.—A reader lately inquired where to get the seed of this, as he liked the flavour of it. At first we thought he referred to the Purple-sprouting Broccoli, which, to the taste of those who know the Kales, is the most delicate of vegetables for the spring. But we have since found that there is another form of Broccoli which makes a head something like a Cauliflower, but rather different in colour, and has the excellent flavour of the Purple Broccoli. Many of the Cauliflowers have a disagreeable after-taste, from which these Broccoli are free. It is curious how a difference in colour often goes with a distinct gain in flavour. Cape Broccoli is the market name for the plant which is grown by market gardeners near London, the seed of which is supplied by Messrs. Watkins and Simpson, Covent Garden.

SAVOURY VEGETABLE COOKERY.

A NICE savoury can often take the place of a pudding, and prove not only economical, but a pleasant change, many people preferring a savoury dish to a sweet. As a rule, a savoury is considered a small "snack," but where strict economy is the rule the savoury can be made one of the substantial dishes of the meal. These dishes are particularly nice for supper. The following is

A DELICIOUS SAVOURY PIE which might be the sole hot dish provided for supper or luncheon. Grease a deep pie-dish with butter or other fat, and cover the bottom with cold boiled Rice which has been nicely flavoured with salt and pepper. Slice a large Tomato and spread thinly on top, then a sprinkling of finely-chopped sweet Herbs and a little finely-minced Onion. Cover this with thin slices of cheese, then a layer of bread-crumbs. Repeat the layers, with a little cayenne pepper, until the dish is full. The top layer should be of Rice. Pour in a small cupful of brown gravy or rich white sauce, add a little dissolved butter on the top, and bake in a hot oven until the top is richly browned. Send to table in the same dish with a serviette folded around.

STEWED CABBAGE is a change from the usual way of serving this vegetable. Take six cupfuls of finely-shredded Cabbage. Only the white heart must be used, the rest can be boiled in the ordinary way. Melt a tablespoonful of butter in a clean saucepan, and fry a thinly-sliced Onion for five minutes, then add the Cabbage and continue frying for ten minutes longer; add a liberal allowance of salt, a pinch of sugar, half a cupful of water, and two tablespoonfuls of white vinegar. Cover closely and cook for half-an-hour. Add a pinch of cayenne pepper, or white pepper if preferred. Roll a dessertspoonful of flour in the same quantity of butter and stir into the mixture. Cook for three minutes longer. Lay a large piece of buttered toast at the bottom of the vegetable dish, pour the Cabbage over, and send to table very hot.

SCALLOPS are always nice as a supper dish and can be made with Jerusalem Artichokes, Parsnips, or Salsafy. Any of these vegetables can be used, with layers of bread-crumbs, pepper and salt, and a little white sauce or stock. The mixture can be baked in scallop-shells or else in a deep pie-dish. The latter is better when the dish is to be the main one at a meal, the shells being used for special occasions. Almost any recipe for scallops may be used. I boil the Jerusalem Artichokes in sufficient water to cover, and a few minutes before they are done I add a cupful of good milk and simmer until the vegetable is quite tender. Then a dessertspoonful of butter is fried in a pan with the same quantity of flour, and the mixture stirred into the liquid of the boiling Artichokes. Have ready a deep pie-dish which has been well greased (butter should be used, as the flavour is nicer). Spread a layer of bread-crumbs at the bottom, sprinkle with salt and pepper, and then add a deep layer of the Artichokes (which must have been chopped coarsely) and sufficient of the sauce to soak the bread-crumbs. Dot a few pieces of butter on top. Repeat the layers of bread-crumbs and Artichoke, finishing with a layer of bread-crumbs. Pour a little dissolved butter on top and bake in a quick oven until nicely browned. Serve very hot. Cheese or chopped sweet herbs may be used to vary this dish, but I think the flavour of the vegetable is nicest when unmixed with anything else.

H. THOBURN-CLARKE.

TREES AND SHRUBS.

OLEARIA AVICENNIFOLIA.

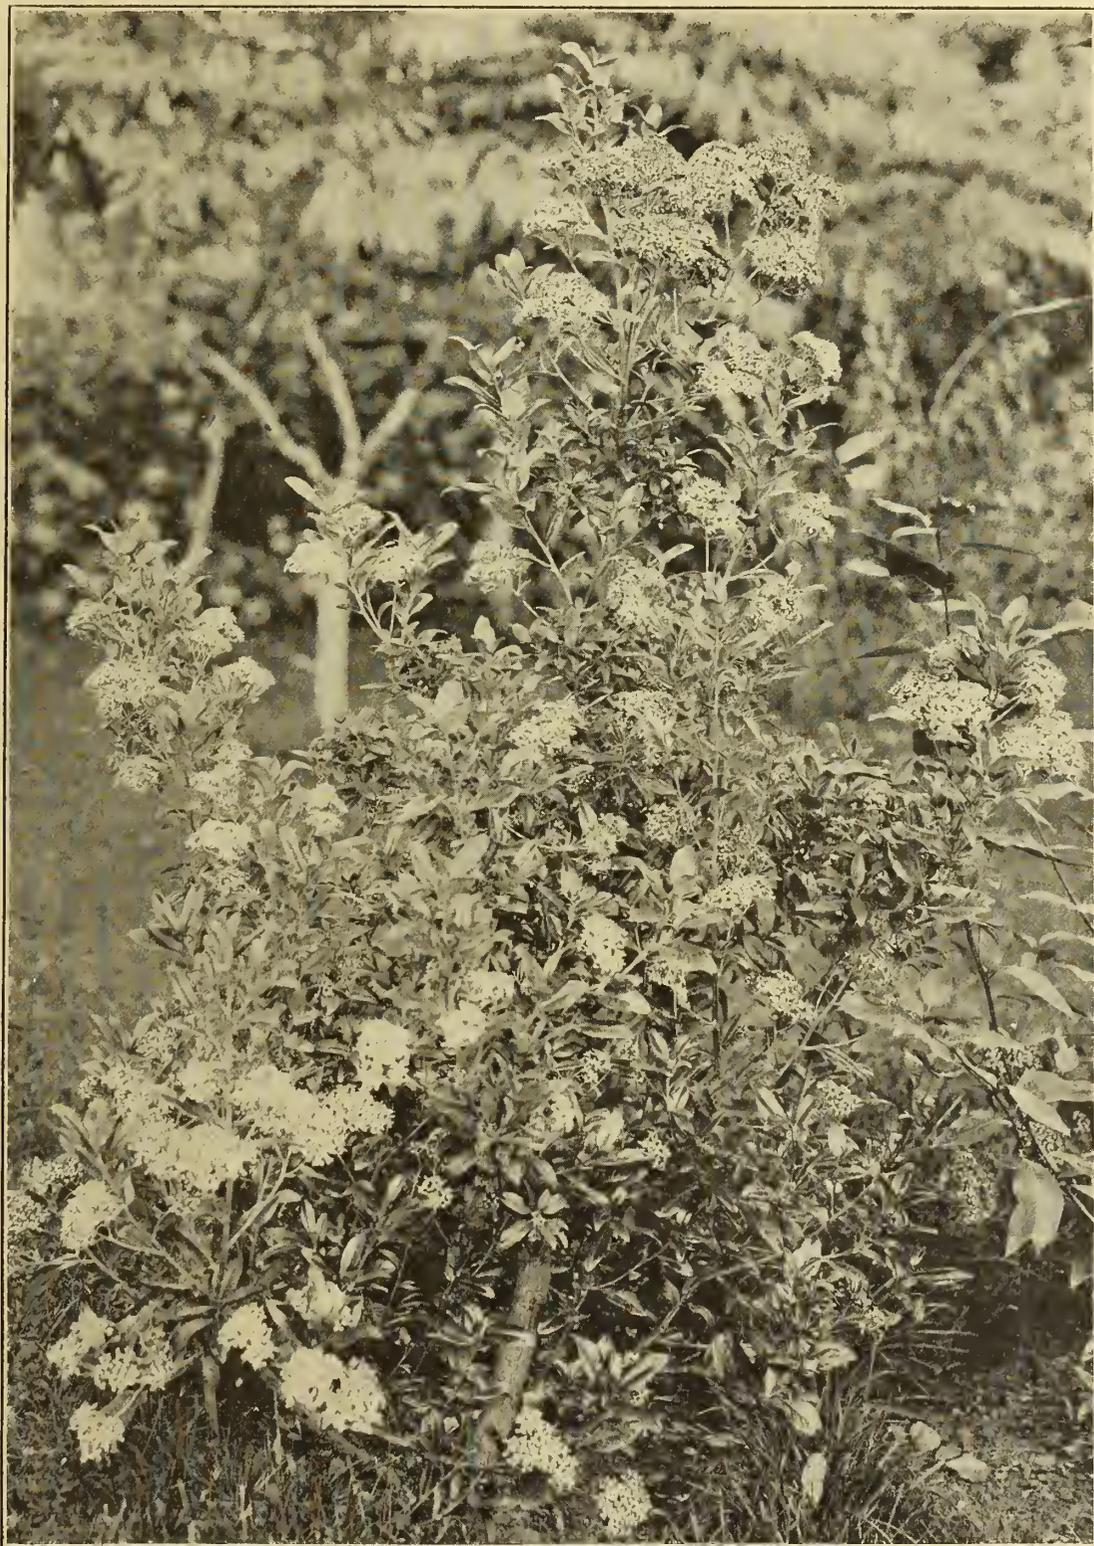

A SMALL branching tree from New Zealand, but apparently hardy in the south of Ireland. Its leaves are glaucous green,

CEANOTHUS GLOIRE DE VERSAILLES.

THE protection of a wall for this handsome shrub is in most cases unnecessary south of the Thames. Although it is undoubtedly very fine when thus grown, there are so many other beautiful plants

margin, and spreading out on the Grass, flower almost as freely as the better-placed growths.

Now is the time to prepare the soil and purchase the plants, which are usually sold in small pots, and are comparatively cheap. On arrival, if root-bound, they

Olearia avicenniifolia at Ashbourne, Glounthaune, Co. Cork.

and its heads of flowers are numerous, white, and last for a long time. The flowers remain upon the tree for months after they have withered and turned to a brown colour. It thrives in the sunniest spot in the garden in poor, open soil, and the wind does not affect its growth.

Cork,

R. H. BEAMISH.

which really require such shelter that it becomes very important to reserve as much wall space as possible for them. For the past ten years I have grown this *Ceanothus* as a group on the lawn, and it is one of the best plants I have used for that purpose. The lower branches droop sufficiently to hide all the soil and turf

should be potted at once and placed, if possible, in a cool frame or house. The site should be carefully chosen. Bear in mind that the height of the plants will probably not exceed 6 feet, and that the colour of the flowers, produced from July to October, is a rich lavender-blue, just the colour which is so valuable to

associate with pink flowers, such as those of Rose Debutante and others. Dig the ground thoroughly, adding anything, such as wood-ashes or leaf-mould, which will help to lighten it in the case of stiff soil, or retain moisture in a light one. Plant out in April 4 feet apart. If the plants were potted when advised the young roots should be showing through the outside of the ball, and in good order to start foraging at once in the new bed. Place a stake to each plant and mulch and water during summer if the soil is light or the weather very dry.

When grown in bush form this *Ceanothus* should be pruned late in February or early in March. If a height of 4 feet is sufficient the previous season's growths may be cut down to within a few inches of their base, but if a taller group is desired the points of the main branches may be shortened only, as in pruning the Red Currant, all side growths being reduced to a few inches. As soon as pruning is finished a coat of manure or other top-dressing may be forked in. Such liberal treatment will encourage vigorous growth and abundant flowers. A shoot 4 feet long will often produce as many as twenty panicles of flowers in summer, and five or six more in autumn.—J. COMBER, *Nymans Gardens, Handcross.*

SOME EARLY-FLOWERING RHODODENDRONS.

ALTHOUGH May and June are usually looked upon as the months for Rhododendrons there are many kinds which bloom at an earlier date, and in mild weather in those gardens where a representative collection is grown one or more sorts may be found in blossom from Christmas until the middle of July. In the south and south-west counties of England and in various parts of Ireland and western Scotland the largest number of early-flowering kinds is to be met with, for there many of the Himalayan species and their hybrids grow luxuriantly, and they are usually at their best before the end of March. In less-favoured localities a goodly number of species, hybrids, and varieties bloom early, though sometimes they are severely injured by frost.

The mild weather of January of the present year was peculiarly favourable for the earliest kinds, and the bright red *R. Nobleum* was in first-rate condition from the middle to the end of the month. Sometimes it does not bloom before the middle of March, and occasionally flowers open in November. Plants 12 feet high and almost as far through are sometimes met with, although it is often smaller. Thirty years ago this variety was grown rather largely in the neighbourhood of Liverpool for forcing. As a contrast to this noble variety we have the small-growing *R. parvifolium*, a straggling bush with thin, wiry branches, small evergreen leaves, and rosy-purple flowers which open in January. It is a native of Manchuria and Korea, and is quite at home in the rock garden. *R. dahuricum* is another January-flowering bush. It is of erect habit, usually deciduous, and bears rosy-purple flowers each upwards of an inch across. The variety *sempervirens* has evergreen leaves. This species is from Siberia, and flowers are often open by Christmas. A closely allied form from N. China, Manchuria, and neighbouring countries is found in *R. mucronulatum*. Of upright habit, it is deciduous, and the flowers, which are pale rosy-purple, are produced freely in January and February. It is more effective than *R. dahuricum* and will probably largely displace that plant as it becomes better known. A few flowers may be found on the dainty little

R. intricatum in February, but it is usually at its best towards the end of March or early April, the point of every shoot at that time bearing a small head of pretty violet-coloured flowers. Of dwarf, compact habit, it will probably not exceed 12 inches in height, but it is of good constitution and is well fitted for planting in groups in the rock garden. Allied species with flowers somewhat similar in colour are *R. fastigiatum* and *R. nigro-punctatum*. A hybrid that has long been popular in gardens is *R. præcox*, an evergreen bush 2 feet to 3 feet high of shapely habit bearing pale rosy-purple flowers in February. It was raised by the late Mr. I. Davis, of Ormskirk, by crossing *R. dahuricum* and *R. ciliatum*. Early Gem is not sufficiently distinct to warrant its being kept separate from *R. præcox*, but *R. Rosy Bell* is a charming kind showing a good deal of the blood of *R. ciliatum*, its bell-like flowers being deeply stained with rose. They are at their best in March. Amongst the

HIMALAYAN kinds one of the finest is *R. grande*, growing sometimes 20 feet high. It has very large evergreen leaves with a silvery under-surface and large, dense heads of creamy-white flowers, the clusters sometimes 9 inches long and as far through at the base. *R. Falconeri* is another very fine Himalayan species, whose dark green leaves are thickly covered with brown felty hairs beneath, and its heads of creamy-white flowers are as large as those of *R. grande*. *R. arboreum* is also a very attractive kind. In the best forms the flowers are blood-red, but there are kinds with light red, pink, and white flowers. As a rule, the plants which have a silvery under-surface to the leaves are fine-flowered kinds. Cornish growers have raised many hybrids, some of which bear larger heads of flowers than the type. In some Cornish gardens the specimens are said to rival those of the Himalaya in point of size, for they are between 30 feet and 40 feet in height, with trunks over a foot in diameter. It cannot be grown successfully in the open about London. Another attractive species with blood-red flowers is *R. barbatum*, recognised by the long, stiff hairs on the leaf-stalks. This should be seen in bloom before being purchased, for there are two forms, one with fine, large flowers, and the other with small and very inferior blossoms. It grows and flowers about London. *R. Thomsoni* is hardier than the last-named and sometimes grows and flowers very well in the Midlands. Its rich crimson, tubular flowers are very effective. It blossoms between February and April. A number of very beautiful hybrids has been raised in Cornwall between this and other species. Good ones are *R. Shilsoni* (crimson), *Gill's Triumph* (very bright red), *Beauty of Tremough* (pink), *Glory of Penjerrick* (rich red), and *Gauntletti* (pink). *R. Griffithianum*, with its immense saucer-shaped white flowers each 4 inches to 5 inches across, is very effective in March in many parts of the milder counties, whilst *R. ciliatum*, a free-flowering bush 3 feet or 4 feet high, with white, rose-flushed flowers, is also an effective shrub.

There are other species which bloom before early April and many hybrids and varieties, but those mentioned will serve to direct attention to the value of the family during the early months of the year. D.

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. Cloth, medium 8vo, 15s.; post free, 15s. 6d. Of all Booksellers or from the office of GARDENING ILLUSTRATED, 63, Lincoln's Inn Fields, London, W.C.

INDOOR PLANTS.

CHRISTMAS ROSES IN POTS.

In your issue of January 29th, in the paragraph "Flowers at Christmas in the greenhouse," you mention Christmas Roses as one of the plants which can be had in flower then. If Christmas Roses are not very difficult to flower in pots, I should be very much obliged if you would let me know what treatment to give them. What size of pots should they be potted up in? What potting soil and what manure should be used, etc.—A. R.

[These plants are not difficult to flower when grown in pots and accorded rational treatment. To lift them at the last moment when the flower-buds are already formed, cram the roots into any convenient-sized pot, and bring them into a heated structure with the sole object of getting the flowers they produce, are wrong in principle and bad in practice. There are many bulbous flowers to be had for greenhouse decoration at Christmas, but they need preparation weeks, sometimes months, in advance, and it is the lack of rational, thoughtful preparation in the case of the Christmas Rose that, in conjunction with subsequent rough treatment—which often includes the return of the plants to their old places in the garden—is one of the chief causes of their undoing. There is no reason why the Christmas Rose should not be more or less permanently grown in pots for greenhouse work if required. During spring and summer the plants could be plunged in the open in a slightly shaded place, and if given attention to watering and feeding they would do fairly well. The qualification is necessary, inasmuch as pot-grown examples would naturally be bereft of soil-depth, and unless the nourishment this contains is not otherwise supplied great success would not result.]

The best time to pot and prepare the plants is during September, at which time healthy bits with three or four good crowns should be potted into 8-inch pots. The soil should consist of good loam with leaf-mould, sand, and a small quantity of well-decayed manure. If at hand a dusting of bone-meal might be added to the whole. Firm potting and perfect drainage are essential. Correctly—i.e., rationally—cultivated, and not forced into flower in strong heat, the plants would be quite good for two years, when they should receive a shift into larger pots. During growth the plants would be benefited by watering with weak liquid manure and soft-water at intervals of a few days. Larger pots, of course, than those named could be employed, but not larger plants than those described. Instead, for pots of 10 inches or 12 inches diameter employ three or five plants of quite medium size. Such as these always transplant best.]

NOTES AND REPLIES.

Hyacinths falling.—Enclosed please find Hyacinths, which were potted on December 6th and covered with ashes up to February 16th. As you will see, there are no roots. I have about 200, all of which are the same as the one enclosed. If you could give me any advice as to what to do I shall be obliged.—C. SPECK.

[There are abundant evidences of mite on the bulb sent, though we believe its condition to be due, in greater measure, to the fungus known as "black smut" (*Sclerotinia bulborum*). The stronger may flower to some extent, though the quality will not be high. If all your bulbs are like the one sent you should forward specimens to those from whom you purchased them. You appear to have planted them very late. You had better, later on, burn the whole lot, also the soil in which they are growing.]

Germination of old seeds.—If seeds are kept dry and cool their period of vitality may be much extended. Never throw

away old seeds till they have been tested, and one way of testing is to place a sample in an earthen vessel like a flower-pot saucer with a little water and place on a hot-water pipe, or, at least, under the influence of heat. Another way is to put some seeds in flower-pots and plunge the pots in a hotbed. I prefer the water-pan on the warm pipe, as one is able to watch the seed swelling from day to day. I think the best way of keeping spare seeds is to let them remain in packets in a close-fitting, airtight tin-box in a cool room. Though I believe new seeds of most things are best, I should never throw away old seeds without testing them in some way. Cucumber, Melon, and Marrow seeds will keep alive a long time. All

light position on shelves suspended under the roof glass. In potting, care is taken to keep the young combs partly elevated above the surface of the soil. A light syringing twice daily serves to promote a speedy formation of roots with a corresponding increase of stout leaf-stalks and firm foliage—A. W.

Sea sand.—During the week a considerable amount of sand was collected upon the beach, not far distant, and carted home. This sand is rather coarse and shelly, but excellent for most purposes. Opinions differ as to the advisability of using sea sand, but for years it has been used here without any symptoms of evil ensuing to plants. It is generally recommended that such sand be washed, but I

WOOD FIRES FOR GARDEN MEN.

In our variable climate shelters in gardens are wanted for various good ends; among others for men's meals and for wet days when work out-of-doors cannot be done. A good, easily-managed wood-fire is, therefore, essential in a country place of any size. It is not unusual to see coal burnt in a grate in such sheds, the coal brought miles from a distant railway station and in places in which there is plenty of wood. I was once in a house in Devonshire where there were hundreds of acres of woodland near, and saw the inhabitants trying to keep warm round a coal fire in a grate ugly with heavy iron bars.

In many gardens and grounds near the

Down fire for country house. In this the hearth of Ruabon brick is raised 10 inches above floor level. The fire-hearth is of cast iron. Fire-back, old Sussex. A simpler, bolder plan should be followed for working shed.

the Cabbage tribe will keep several years. Onions also, and many others. Carrot seeds will grow the second year, but are not reliable after.—E. H.

Seedling Cyclamens.—The young plants raised from seed sown last autumn, and which were subsequently pricked off into pans, are now ready for transferring to 3-inch pots. These will be well drained and a piece or two of flaky loam placed over the crocks. The compost, consisting of one-third good fibrous loam, one-third leaf-mould, one-third peat, with a liberal addition of sand and a small quantity of fine lime-rubble, will be placed in warmth a day or so before potting takes place. Potting will be done in the house in which the plants are growing, and when this is completed the plants will be accorded a

use it just as it comes from the beach, where it is covered by every tide.—KIRK.

Manuring Ferns.—In the article on "Hardy Ferneries," in your issue for January 29th, "A. G." mentions that Ferns object to manure either in a liquid or solid form. I have never found it so in my long experience. I do not say that it is necessary for Ferns planted out, though they certainly benefit by it, but for pot plants and indoor ferneries it is necessary for their welfare. I planted a fernery about twelve years ago, and the Ferns are doing splendidly. The gardener told me he sprinkled a little artificial manure on the soil and watered it in.—G. P. EGGETT.

New Index and Binding Cases for completed Volume.—The Index to Volume XXXVII. of GARDENING ILLUSTRATED is now ready (price 3d., post free 3d.). The Binding Case for the same volume is also available (price 1s. 6d., by post 1s. 9d.). The Index and Binding Case can be obtained from any newsagent, or from the Publisher, 63, Lincoln's Inn Fields, London, W.C. If ordered together, the price of the Index and Binding Case is 2s., post free.

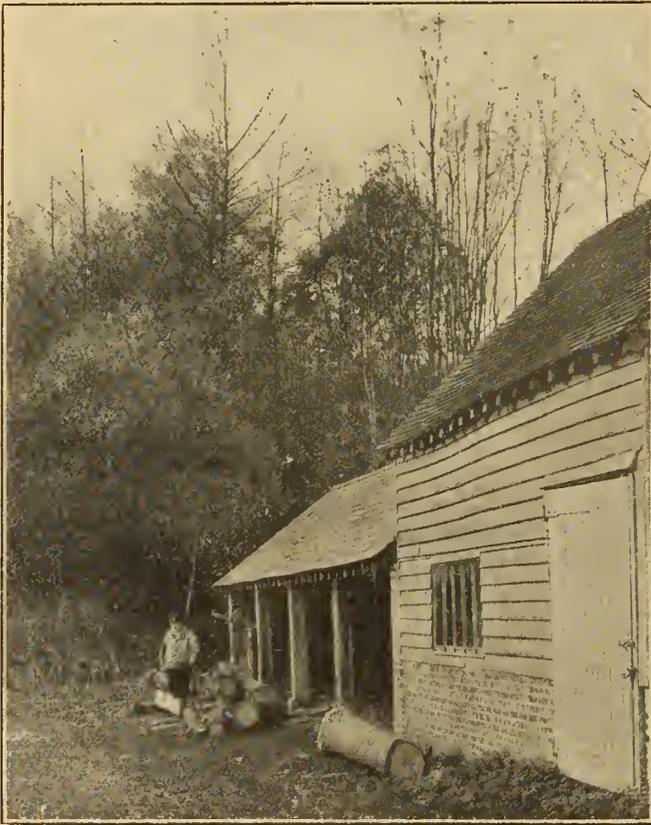

house, owing to the overplanting of rampant evergreens, there is usually much wood that wants clearing, and trees also out of place, like solitary Cedars, that the wind knocks over. These might be a source of wood to feed the fire on the hearth. There should be no grate, but the simple old-fashioned down hearth. Any boy can light such a fire, and a well-made hearth will last for generations—unlike the flimsy kitcheners and grates that often get out of order. Such a fire may often be fed from the refuse wood of the garden and pleasure-ground.

The mixed muddle shrubberies that pretended landscape gardeners plant are a frequent source of fuel as the ill-chosen trees begin to kill each other. The woodlands in a place of any size should give

plenty of "batwood" for burning from the mixed underwood which has to be cleared periodically.

In every place where wood is well used there ought to be a comfortable shed for the woodmen to work in on days when work out-of-doors cannot be done. It should be open in front and have a sound roof. The back may be against a shelter, but the front should be open to the sun and air. Near should be, as in this case, a shed for housing tools, and any empty sheds or barn near might be used for storing wood.

In such a wood-shed many things of use in gardens may be prepared, such as posts and rails for fences, gate-posts, stakes for Peas and climbing Beans. The use of wire on walls is not so picturesque as the old way of training on Oak and Chestnut stakes, and these can be easily made in bad weather by the woodmen.

Open wood shed for wet-day work and tool-house for woodmen. Gravetye. (See page 137.)

The recent gale has thrown over many fine trees, not only common ones, like Elm, Beech, and Fir, but also some more precious ones, like the Cedar of Lebanon. Very often this loss occurs where there is no means of using all the branch wood in the right way—that is, the old hearth fireplace, best raised 8 inches to 10 inches above floor level, a good draught and good level hearth of fire brick, or, as I prefer, a rough cast-iron plate and iron fire back, too. Every country house should have such fire-places.

A thing worth considering is the black filth of the Newcastle coal as it affects delicate flowers near the house. Before I mastered the question of wood fires my Tea Roses round the house were often dotted with the blacks of this coal. The adoption, therefore, of wood fires for hall and sitting-room would be a great gain to the flower garden. W.

FRUIT.

DESSERT APPLES AND PEARS IN PRIVATE GARDENS IN ENGLAND.

Most of us will agree that the choice in dessert Apples of first-rate quality is a very limited one if we fix the standard as high as Ribston or Cox's Orange Pippin. The nurseryman's catalogue teems with varieties, good, bad, and indifferent, but we cannot say that the description given as to quality is often realised by the grower who plants the trees. No doubt locality and climate have something to do with it, but, apart from these influences, are not our catalogues full of worthless sorts of Apples, which should be ruthlessly eliminated, or, at any rate, the warning words "For exhibition only" put in italics against them? Then, again, look at the many recent crosses, especially with Cox's. Evidently size, appearance, and

Wyken Pippin, Lord Burghley, and King's Acre Pippin. I am also told that the following are good and worth a trial, namely, Ashmead's Kernel, Rosemary Russet, Belle de Fontenay, and Reinette de Canada. I might add that I have made a fairly exhaustive test of well-known advertised varieties up to date, and it is surprising how few of them come up to their catalogue description in my garden, or can be described as even good, let alone of first-class quality.

I have only dealt with the question of the later Apples, as these interest me most. Undoubtedly there are a good many early Apples which are delicious if picked from the tree and eaten just at the right time. Most of these, however, if not all of them, entirely lose their quality and flavour if kept any time.

When we come to consider Pears it is a different matter. Thanks to the efforts of Continental growers we really have a good number of first-class varieties for all seasons. Keeping strictly to the later varieties it is not difficult to select six first-class sorts. Moreover, speaking generally, one can place more reliance on the descriptions given in the catalogues. Nevertheless, we still find such a variety as Pitmaston Duchess upheld as a first-class Pear. If ever a fruit wanted "For exhibition only" printed against it in the catalogue this is the one, yet we find the market inundated with it, and the public having to buy it during its season from lack of a better variety. It seems such a pity that this should be so, seeing that there really is a good choice so far as Pears are concerned. F. B.

Springfield, N.

PLANTING DORMANT VINES.

THE present is a good time for planting Vines in a dormant state, either for the purpose of introducing any particular variety to a viney already furnished with rods, the planting of a newly-erected house, or when replanting has become necessary as a result of having had to discard the former occupants. The soil should be carefully washed out from among the roots, which enables their being disentangled the more readily, and also allows of their being laid out, when planting takes place, with greater facility. Holes large enough in length and width to accommodate the roots when spread out regularly and straight must be opened beforehand. The roots, when covered, should not be deeper than 6 inches from the surface. It is a good plan to work in some fine, sandy soil among the fibrous roots, this inducing greater and quicker activity of growth than if covered with the compost of which the border consists. If the canes have not been cut back to the point or buds from where it is desired to train or take up the new rods, the buds as they break must be rubbed off down to that point, as cutting back now would lead to a great loss of sap by bleeding. If the border is inside the house the soil should be settled into place about the roots with a good soaking of water in a tepid state. Watering for the present is best omitted in the case of an outside border, placing a mulch of short litter over the roots instead. G. P. K.

NOTES AND REPLIES.

Raspberries.—Is not "F. K.'s" plan, February 19th, page 84, of making a new bed every year most unusual, not to say unnecessary? Given 2 feet deep of heavy loam, as he advises, there does not seem to be any need for planting annually. In such soil, given proper attention, they ought to do well for from three years to five years—in fact, in many gardens they stand longer, yielding quite good results. This winter I have taken up and replanted in new ground part of a bed that I understand had not been disturbed for eight years or ten years, and which were still

colour count a long way before anything else with the raisers. They consequently select such Apples as Worcester Pearmain, Peasgood's Nonsuch, etc., to cross with Cox's Orange Pippin. How can we expect to have really fine dessert Apples from such crosses? It is abundantly evident that appearance comes a long way first, with flavour and quality nowhere. One of the finest English Apples known, D'Arcy Spice, is not beautiful in appearance, but it has all the other virtues. I recently endeavoured to make out a list of six first-class second season and late dessert Apples, but after getting as far as D'Arcy Spice, Ribston, Cox's, and Claygate Pearmain I could get no further with any certainty. There are, of course, many other varieties which are good, but D'Arcy Spice, Cox's, and the Ribston seem to tower like giants over the lot. For instance, the following I consider good Apples from personal experience:—Margil,

doing fairly well. I have strong, moist soil to deal with, and where such exists a bed of Raspberries, if properly made at the time of planting, can remain for several years. What does "F. K." mean by cutting the canes lower down to obtain late fruits? He has previously referred to Superlative, the ordinary summer variety, and I have never practised any cutting down beyond old canes, supernumary canes, and unripe tips after training has been done.—C. TURNER.

["F. K." refers to the plan which, to our knowledge, he practised for many years of cutting down Superlative in the same way as the autumn-fruited varieties are treated. We have seen Superlative carrying heavy crops when treated in this way.]

Pears for retaining wall.—I have a retaining wall, only very slightly battered (certainly not exceeding 6 inches in 6 feet), soil at the back about 6 feet, faces southwest, sub-soil very sandy. The wall is about 25 yards long, no buttress outside, height 7 feet, but could be built up if necessary. (1) Is it suitable for growing choice Pears as cordons? If so, do I plant close against wall or would it be better to grow against strips of wood nailed to wall? If necessary, trees could then grow quite upright. *Yes; allow stems at base to be distant 6 inches from the wall.* (2) Kindly name good Pears, including early, mid-season, and late? Early: *Beurré Giffard, Beurré de l'Assomption, Fondante d'Automne, Souvenir de Congrès, Mme. Treve, Summer Beurré d'Arenberg, Belle Julie, Autumn Nelis.* Mid-season: *Beurré Hardy, Beurré Superfin, Comte de Lamy, Louise Bonne de Jersey, Marie Louise, Charles Ernst, Doyenné du Comice, Thompson's Fondante de Thirriott.* Late: *Nouvelle Fulvie, Winter Nelis, Josephine de Malines, Le Lectier.* Very late: *Olivier de Serres, Président Barabe, Beurré Pervan.* (3) Are Ribston and Cox's Orange suitable as cordons? *Yes.*—FOUR OAKS.

VEGETABLES.

OUTDOOR TOMATOES.

Those who grow Tomatoes in the open, stand the most likely chance of success if they have a south or east wall or boarded fence at command. It matters not if it is but 4 feet high, as to allow of greater length the plants can be trained obliquely. With such conveniences success in an ordinary season is almost a certainty. The greatest mistake is that of not having the plants large enough at planting time, owing to late sowing. As a rule, the plants cannot be put out with safety until the end of May. At that time they should be at least 1 foot high, sturdy, and growing in 5-inch pots; if 6 inches higher, and proportionately stocky, all the better. Such plants, directly they take hold of the soil, commence to show flower-trusses, and if carefully managed as to watering and the regular removal of all side shoots, confining the plant to one stem, there is not much trouble in obtaining a "set" of fruit. When once this is assured the full height of the plants the point should be removed to concentrate the energy of the plant into the development of the fruit. I would, therefore, emphasise the absolute necessity of preparing the plants in time by sowing at the end of March seed of an approved variety. In reds good varieties are Sunrise, Holmes's Supreme, and Up-to-date. If a small-fruited yellow is required then Golden Nugget may be chosen.—S. H.

Cabbage Little Gem.—Those who have space and can grow the best type of summer Cabbage will find Little Gem an ideal variety. Tender, quickly-grown, small Cabbages come in useful between the Peas,

Beans, Marrows, etc., and, by many, are much liked. I have chosen the above variety for summer use on account of its flavour, which is mild and not readily influenced by the weather. As its name implies, it is very dwarf, making a close, compact growth with few outer leaves and a short stem. When full-grown it is one of the best to remain solid a long time. Owing to its compact growth it does not require so much room as the larger growers, a distance of 18 inches to 2 feet being ample between the rows. I would not advise sowing too early for late summer use, a season of the year I have found it most useful. April or early May sowings will give good material.—C. R.

Notes on vegetable culture.—Amateurs, even those in a small way, are turning their attention more to vegetable culture, and it is important to sow or plant only when the land is in a suitable condition, which means that the soil has been enriched and sweetened by exposure to the atmosphere. The waste materials of house and garden should be collected and made the most of by passing through the fire. Early Potatoes, such as May Queen, Duke of York, Ninetyfold, and others should be placed in boxes, crown upwards, to start. The best and strongest eyes are in the crown, and when a couple of the strongest are started the others may be removed, as by so doing there will be a crop of even-sized tubers. If such prepared sets are planted in March we may reasonably expect a good crop. Cabbages may be set out and the plants already in growth may have a little earth drawn up to their stems as a support. Onions should be sown early in March, Early Horn Carrots also, and Turnip-rooted Beet, but main crops of most things will be in time enough if sown in April. When Onions are started in February under glass they should be planted out in April and room given to develop. Where glass is available early vegetables and salads are now on the way. In country districts a good deal of vegetable forcing can be done on beds of leaves.—E. H.

Early small Radishes.—We now have some remarkably quick growers, the best in this respect being the small varieties, which are not great favourites for market. Early Rose, a variety with a remarkably small top, is an ideal Radish for first supplies, as it comes so soon to maturity. For years I found it a good plan to sow this on a well-drained, warm border, covering at night with dry Bracken or litter, removing this as the sun reached the quarter next day. Other good small early forms are the White Olive, Forcing Carmine, and Earliest of All. The last only makes three or four small leaves. If large roots are desired there is no lack of excellent varieties, such as French Breakfast and Early Frame, both good. These do well when sown a little later for a succession. No matter what variety is grown it is important to protect, as advised, from frost, taking care to remove the protecting material whenever possible to admit sun and air.—C. F.

Parsnips, hardness of.—Last year I grew some for seed, and not being able to get a portion cut when ripe, some of the best heads dropped their seed. When the crop was cleared, the ground not being wanted, the seeds were left on the surface of the soil. In October I noticed that the seed had germinated, and I resolved to allow the seedlings to remain for another crop. Now, early in February, the plants look well, having grown during the mild weather. I noticed during the frost we had in November that the young seedlings, only just coming up, did not suffer. Wishing to test the hardness of the seed, I sowed a row beside them at the close of January. I intend sowing again in March and May. I shall be interested to see if these self-sown autumn plants run to seed.—WEST SURREY.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM FEBRUARY 24TH.—*Rubus biflorus, Arbutus canariensis, Ericas (in variety), Forsythia suspensa, F. spectabilis, the Purple Plum (Prunus pissardi), the Cornelian Cherry (Cornus mas), Laurastinus (various), Azara microphylla, Daphnes (in variety), Periwinkles, Berberis (in variety), Genista hirsuta, Gorse, Osoberry (Nuttallia cerasiformis), Cydonias (in various colours), Yew, Alnus (various), Hazel (various), Edgeworthia chrysantha, Osmanthus Delavayi, Coronilla glauca, Andromeda (in variety), the Goat Willow (Salix caprea), Crocus (several species and varieties), Dog's-tooth Violets (Erythronium Dens-canis), the Carpathian Snowflake, Arabis (double and single), Aubrietia, Primroses, Violets (in great variety), Galanthus (in variety), Chionodoxa sardensis, C. Lucilia, Scilla sibirica, S. taurica, Polyantheses, Narcissus pallidus praecox, N. maximus, N. minimus, N. Grand Mouarque, N. Tazetta, the Tenby Daffodil, Saxifrage (in variety), the Scarlet Wind-flower (Anemone fulgens), the Greek Wind-flower (A. blanda) (various colours), the white Wood Anemone (A. nemorosa alba), the Poppy Anemone (A. coronaria) (various colours), Aconites, Tritelia uniflora, Lenten Roscs (in various colours), Puschkinia scilloides, Blue-eyed Mary (Omphalodes verna), Iberis, Hepaticas (in various colours), Violet Cross, Hyacinthus azureus, the Algerian Iris (I. unguiculata), the Netted Iris (I. reticulata), Wallflowers, Barrenwort (Epimedium sulphureum), Viola gracilis.*

WORK OF THE WEEK.—A further plantation of *Acer colchicum rubrum* has been made along the banks of an old lane. The site comes well under the eye when seen from the house. A hundred *Larix kurilensis*, having come to hand in a small state, have been planted in rows 18 inches apart in the nursery until they can be safely transferred to the woods. A few plants of *Sedum purpureum* have been added to an existing group which has been naturalised in the Grass. Sweet Peas sown early in February are now growing freely, and have been transferred to cooler quarters. Seeds of *Celastrus scandens*, *Decaisnea Fargesii*, *Holboellia sinensis*, African Lily, *Ipomoea*, etc., have been sown in pans and stood in a warm-house; a slate or piece of glass cut to fit is put over the top of the pans. I prefer slate until the seeds have germinated, as it does away with the daily shading necessary when glass is used, and is equally satisfactory. Cannas and Cardinal *Lobelia* for the flower garden have been overhauled and potted into 5-inch and 6-inch pots, the former placed in heat and the latter in cool-frames. The *Lobelia* were very badly infested with wireworm, which eats away the roots in winter and eventually finds its way to the heart of the young growths. So badly were some of them attacked that whole boxes had to be destroyed, the rest were carefully cleaned over, and will be given a fair amount of lime whenever watered. A batch of Shamrock Pea, struck from cuttings inserted in autumn, has been potted off separately, also a batch of *Verbena*. Monroe's Mallow and *Felicia abyssinica* are all nicely on the move, and will be given cool treatment. Various forms of the Apennine Anemone, the double white Wood Anemone, and the blue and white Italian *Scilla* have been planted in the Grass. *Triteleia uniflora* and its deeper coloured form were planted to form an edging in the Azalea garden. Allium

Moly and Camassias in variety have been put among cut-down groups of Rosemary, while rare Narcissi and other choice subjects have been planted in the nursery. A group of Rosemary has been planted on a steep bank, and a further batch of *Erica mediterranea hybrida* has been put below Azaleas. An overgrown line of *Epimedium sulphureum* has been lifted, split up into medium-sized pieces, and replanted a foot apart as an edging to a young plantation of the Nootka Cypress. E. M.

Sussex.

SOUTHERN COUNTIES.

Calceolarias.—These must now be lifted from the bed in which they were inserted as cuttings last autumn and planted out 4 inches to 5 inches apart each way in a frame. Treated in this way the plants can be lifted with good balls. As soon as the plants begin to make new roots the frame will, whenever circumstances permit, be freely ventilated. To promote a sturdy and bushy growth frequent stopping of the shoots is resorted to.

Pentstemons.—These do best when treated in the same way as Calceolarias, but unless it is possible to get them planted out early they need a trifle more space for development, otherwise they are apt to become drawn. They do not require to be stopped so severely as Calceolarias, but at the same time a certain amount of it is imperative. Coddling is to be deprecated, and the more naturally they are grown the more satisfactory are the after results. Unless a very severe frost is apprehended merely closing the frame at night suffices in the way of protection.

Pansies.—A quantity of Pansies raised from seed sown last autumn will now be pricked off into boxes and given frame treatment for a few weeks; they will be used to take the place of some of the half-hardy annuals generally used for summer effect. The seed was saved from the best and choicest large-flowered varieties.

Herbaceous borders.—As the whereabouts of most of the plants grown in these borders is now visible the soil will be forked over between them and all made tidy for the season. Part of the portion next the lawn being used for such hardy annuals as harmonise with the herbaceous plants will be dug up and prepared accordingly. The surface will be left rough so that it may become weathered and sweetened. Finally rake down and form a good seed-bed for the sowing of the seed early in April.

Sweet Peas.—A long row will now be sown outdoors to supply flowers for cutting after those raised in pots are past their best. The varieties favoured are those of the large frilled type. The seed is thinly distributed in the drills, which at this date are drawn more shallow than will be the case for the next sowing. The pot plants alluded to are now in a cold pit, where they have abundant ventilation on every favourable occasion.

Violets.—Having a surplus of the double varieties, suitable pieces or cuttings will be detached from the plants and dibbled into boxes filled with light, sandy soil. These will be placed in a cold frame and shaded from direct sunlight until new roots are formed, when the frame will be ventilated in accordance with weather conditions until the plants become established and ready for planting out. The object in doing this is not so much to gain time, and have the plants in a forward condition when the time comes round to plant them in frames as to avoid so much labour in watering which is entailed for some considerable time

when the plants are pulled to pieces after they cease flowering and the selected portions planted at once outdoors. Until they form new roots, and get a grip of the soil, they must, if the weather is dry, be kept regularly watered, but if sufficiently rooted in advance, so that each, when lifted, has a ball of soil attached to the roots, much less attention in this direction is then needed. Suitable well-rooted pieces of the single varieties being always available, it is unnecessary to take the same amount of trouble with them.

Frame Carrots.—These should now be thinned to a couple of inches apart in the drills, and when completed a good watering applied with a rosed can will again settle the soil into place about the roots. By closing the frame moderately early on fine days the roots develop the more quickly. The frames must be well aired in the forenoon otherwise top growth alone will result.

Early Cauliflowers.—Frames for the moment not being at liberty into which to prick off the young plants from recently-sown seed, they are instead being dibbled into boxes which will be put into slight warmth for a time, and the plants lightly shaded until the roots get a hold of the compost. They will then be moved into a cooler place and finally planted in a frame. Brussels Sprouts being in the same condition as the former in regard to growth will be similarly dealt with.

Jerusalem Artichokes.—The plot these are to occupy has been given a dressing of manure. Digging and the planting of the tubers will, therefore, now be undertaken at one and the same time. The rows will be 3 feet apart and the tubers 1 foot distant from each other in the rows. On the completion of planting, the plot will have to be securely netted round to keep out rabbits, which otherwise will eat off the young growths as fast as they appear above ground.

Onion sowing.—Directly the soil can be had in a suitable condition the seeds will be sown in shallow drills drawn 1 foot apart. Profiting by the experience gained since the war broke out a still larger area will be devoted to this crop this season. The firming of the soil when closing in the drills with the feet after sowing, suffices on our heavy soil, no rolling being required.

Globe Artichokes.—The protective material, whatever it may consist of, may now be removed and vacancies made good. Where provision for doing so was not made last autumn by potting up some suitable side growths, and placing them in a cold pit, dig round the outside of some of the largest of the stools and detach the best of the young growths with roots attached. Globe Artichokes appreciate a warm position and a deep, rich soil. To keep the soil in a fertile condition a good dressing of well-rotted manure should be dug in between the stools every year.

Hardy fruit.—The loosening of fruit-borders and the pointing between and under fruit-trees, as well as of alleys, have been brought to a conclusion. The tipping of summer-fruiting Raspberries has also been finished and Peach and Nectarine trees protected with three thicknesses of netting. Trees and stocks which are to be grafted should now be cut back to near where the scions are to be worked on, the remaining portions to be cut off when the actual grafting is about to take place. The bloom buds on Pears are very plentiful, but in far too forward a condition for the time of year. The blossoming of fruit trees generally promises to be very profuse.

Shadings.—These must now be repaired and put in working order, as the heat of the sun daily becomes more powerful and shade cannot, therefore, be longer dispensed with. A. W.

MIDLAND COUNTIES.

Amaryllises (*Hippeastrums*) that have finished flowering must be occasionally given some liquid manure to assist in the development of the foliage and the building up of the buds. This must be continued until the leaves begin to turn yellow, when water should be gradually withheld.

Calanthes will soon require repotting, therefore it is advisable to get in a sufficient quantity of good fibrous loam, and place it where it will get just warm, but not too dry.

Liliums in pots, having made an inch or so of growth, have been removed from the plunging-bed and placed in cold frames. When well rooted, batches are introduced to gentle heat as required. By placing a small batch in heat once a fortnight a constant supply is maintained and the flowering season prolonged until autumn. The varieties I use for forcing include *L. longiflorum Formosanum*, *L. longiflorum giganteum*, *L. speciosum rubrum*, *L. speciosum magnificum*, and *L. auratum*. The earliest batch of *L. longiflorum Formosanum* is now in flower.

Salvia azurea grandiflora (syn. *S. Pitcheni*).—There are several *Salvias* which flower during November, December, and January, but the above, I think, is the most beautiful of all, and probably the least grown. This is to be deplored, as its colour—a lovely azure-blue—should ensure it a place in every garden. (It is much preferred here to the scarlet *Salvia splendens*.) This *Salvia* is easily propagated from cuttings inserted in sandy soil and kept in a warm greenhouse temperature. The present is a suitable time to insert the cuttings, as this variety requires a rather longer season of growth than some. As soon as struck, the cuttings should be potted off singly, and in a few days have the points of the shoots pinched out to encourage a bushy growth. When well hardened off these plants may be stood out-of-doors during summer and treated like *Chrysanthemums*.

Violets in frames should be copiously watered in the early morning when it is found that the soil is getting dry, choosing a bright day for doing this. Do not leave decaying matter about the plants, and remove the lights daily during favourable weather, tilting them at night if not frosty. At this season efforts must be directed to maintaining a healthy stock of plants from which to propagate next month. Red-spider will give little trouble if the soil of the beds is kept in a moist condition and the plants occasionally syringed, especially the lower sides of the leaves, doing this with a nozzle syringe in the forenoon of warm days, afterwards leaving off the lights so as to disperse the over-abundant moisture before nightfall.

Evergreen shrubs.—I do not advocate the formal cutting of evergreens with the knife or shears, but it is necessary to look over banks of shrubs and single specimens once a year, cutting back here and there any branches which are inclined to upset the balance of the shrub. Some of the variegated Hollies are apt to produce growths with quite green leaves. These should be removed each year, for if allowed to remain, the green-leaved shoots increase. The present is the best time for this work, as back buds will push freely soon and hide the effects of the knife.

Perennials for growing in shrubberies.

—Some of the stronger-growing Asters, as the *Novi-Belgii* and *Novæ-Angliæ* types, are excellent, as they make good growth and require no attention. They also make useful material for cutting. Other plants that do well in similar positions are *Delphiniums*, *Heleniums*, *Solidagos*, *Polygonums*, *Pæonies*, the best varieties of *Foxgloves*, etc.

Campanula pyramidalis and C. caly-canthema.—Plants raised from seed sown last year are now ready for planting where they are intended to flower. The sites should be well manured and deeply dug. Plant firmly, allowing plenty of space for full development.

Gladioli.—Any corns starting into growth may be grouped in the hardy plant borders, in beds by themselves, or amongst dwarf shrubs. The soil should be well prepared by deep digging and manuring.

Carrots.—As soon as the soil is in a suitable condition, the first bed of Carrots will be sown in the open, choosing a warm border. Much may be done to assist germination by placing litter over the beds at night and during frosty weather. For this sowing *Early Gem* is one of the best.

Cauliflowers.—The lights are removed from autumn-sown Cauliflowers on every favourable morning, and unless the weather is frosty tilted at night, so that by the end of the month they will be quite hardened and ready for planting out in a rich and sheltered part of the garden. Nothing is gained by putting these plants out before the weather is settled. The young plants raised from seed sown six weeks ago have been pricked into a cold frame in good, rich soil, where they will make rapid progress and form a close succession to those raised in the summer. A sowing of *Magnum Bonum* and *Early Snowball* will be made on a sheltered

Victor, Ashleaf, and Duke of York are good first early varieties. The last-named is very prolific and of good flavour in this locality, and may be classed as one of the best earlies. In this locality it is yet too early to plant Potatoes in quantity, but much may be done now to ensure success by laying out the sets thinly, as previously advised. F. W. GALLOR.

SCOTLAND.

Hardy plant borders.—The work among the hardy plant borders was, for the present, completed in the beginning of the week. The advancing season makes these borders, apart altogether from the display of bulbs, very interesting. The various shades of green, already in evidence, contrast well with the purple and red stems of the different *Pæonies*, which are a trifle further advanced than is generally the case so early in the year. One plant, *Artemisia lactiflora*, is exceptionally far on, the foliage at this time being notably earlier than usual. Such plants as require re-labelling will be attended to when the soil is drier; meantime, the necessary labels, of a good size and length, have been got ready.

Rose borders.—Contrary to the usual practice, Rose borders have been lightly dug over after a dressing of manure was given. In a general way the annual stirring up is deferred until after the pruning is completed. On many of the Roses growth is far advanced, *Zephrin Drouhin*, indeed, showing quite a good lot of buds.

Pricking off has claimed some attention during the week, Leeks, Onions, Parsley, Cauliflowers of sorts, Lothian Stocks, and a few of the other earlier-sown seeds having been handled. Until growth is noticeable these things will be kept in a fairly brisk heat; afterwards they will go into cooler quarters.

Beds in spare cold-frames have been prepared in anticipation for the reception of seedlings of the various kinds of Brassicas. These, pricked off into such beds, always make plants of the very best type, and well repay the little time consumed in the pricking off. The beds in the frames were forked up, and an addition to the present soil was made by allowing about 4 inches of finely-sifted and well-decayed vegetable mould to each sash. In such soil plenty of fibrous roots is formed, and the plants lift with excellent balls and go ahead without a check when put out. When time can be spared for this pricking off, the course is always followed, the plants being altogether superior to those raised in the ordinary way.

Seed-sowing is now of almost every-day occurrence. The bulk of *Lobelia* seed has been sown, while a pinch of a good strain of *Begonias*, the same of *Gloxinias*, *Perilla*, *Primulas* of different kinds, *Ageratum*, and such like has been put in. A light, not too rich, soil is preferred for seed sowing, and a good heat is given until germination is assured. Minute seeds like those of *Begonias*, *Gloxinias*, etc., are scattered evenly on the pans, and lightly pressed into the soil, no covering being given. Sheets of obscured glass, or of glass covered with paper, are then placed on the top of the pans, watering being done through a very fine rose.

Potting.—A quantity of *Salvias* has been taken from the propagating-case and put into suitably-sized pots. These are for planting out. Their places were immediately filled up with a fresh batch of cuttings. Similar treatment was given to a number of double *Petunias*. Well-rooted young plants of brightly-coloured *Coleuses* have gone into 3-inch pots. Some pieces

A Rose border.

When the ground has settled let the corns be planted 6 inches deep, and before covering with soil sprinkle them with soot to ward off slugs. When the corns are grown for cutting, it suffices to draw deep drills 9 inches apart in well-prepared soil and plant the corns 6 inches apart. Any that have not started may be planted in two or three weeks' time, and thus form a succession. *M. Lemoine's* hardy hybrids are dwarf and beautiful early-flowering varieties. *G. Childs* is a fine robust race of *Gladioli*, the flowers of great size and substance. *G. Gandavensis* varieties, as regards brilliancy and variety of colour, are unequalled. *G. brechleyensis* is one of the hardiest, and the best for planting in shrubberies.

Carnations will be benefited by a sprinkling of soot or Carnation manure, lightly pricking it in with a fork. A good dressing once or twice in the spring also prevents the sparrows eating the tips of the plants.

border, so that there may be no break in the supply from the time the first heads are cut from the autumn-sown plants until *Walcheren* and *Autumn Giant*, sown a fortnight later, bring the season to a close.

Brussels Sprouts should be sown now for the main crop. This vegetable requires a long period of growth, and those who sow late rarely see such fine buttons as the plant is capable of producing.

Potatoes.—The first planting of early varieties of Potatoes in the open will now be made on a warm border, where protection can be afforded if necessary, as the crop is not out of danger before the middle of May. My soil being rather heavy, a liberal dressing of leaf-soil and wood-ashes is worked into the staple, also a little of the same material sprinkled into the furrows with the sets. The sets should be planted about 6 inches deep, 20 inches from row to row, and 12 inches to 15 inches from plant to plant in the rows. *Sharpe's*

of *Pancretiums* having become rather too crowded, several potfuls were broken up and repotted—three bulbs to a 9-inch pot. In a year or two these will make excellent plants, and, as the repotting was done with as little disturbance to the roots as possible, it is expected that these bulbs will flower as usual in the course of the season.

Statice profusa.—Some cuttings of this most useful greenhouse plant were put in during the week. This, apart from its intrinsic value, lasts well when in bloom; and as it is not, nowadays, so commonly met with as was at one time the case, it invariably attracts attention when in bloom. In my own experience cuttings of *S. profusa* are not so easily managed as the majority of greenhouse plants, being liable to damp off before roots are formed.

Tomatoes.—A full sowing of Tomato-seed was made during the week. The plants are intended for pots, and will be kept moving from the beginning. For this purpose but one variety is used, *Perfection*, which, if now somewhat old, gives a good return, the bunches being large, and the fruits uniform alike in size and in colouring. For pots, nothing is gained by using too many varieties, it being better to rely upon a single sort of proved excellence.

Ivy-cutting.—A beginning has been made with the annual clipping of Ivy upon walls and gables. It is customary to delay this work until March is well advanced, but, under present conditions, when time can be spared at this time, it is advisable to get it done. Even if the young growths get nipped by a late or severe frost, they soon recover. Where neatness is essential the garden shears is used, but in out-of-the-way corners much quicker work can be done by using an ordinary reaping-hook, and if a little care be taken the result is not noticeably inferior to that produced by the shears. Immediately after any given stretch is completed, the clippings are at once removed to the fire-heap, and where these fall into parks occupied by cattle they are swept up in order to prevent accidents.

Plant-houses.—Some further work in the way of cleaning, etc., was done during the week. Vaporising was done in a greenhouse, not because there was any real need, but to prevent any possibility of aphids becoming troublesome upon *Cinerarias* or upon *Arum Lilies*. These plants, at this time, are easily infected, and prevention is better than cure. A trifling outbreak of mealy-bug upon a roof plant of *Mandevilla suaveolens* was promptly dealt with, the only plant in the garden upon which it is known to exist. A close watch is, therefore, kept upon it, and whenever any insects are noticed, a brushful of methylated spirit soon puts an end to them. The display of bloom in plant-houses is satisfactory, and there is plenty of material for cutting. Greenhouse temperature from 55 degs. to 60 degs. at night, stove round about 65 degs., with a slight fall in both cases towards morning or during frosty weather.

Vegetable garden.—It was intended to make a start with the preparation of the soil for sowing and planting in the course of the week. When time would have permitted, however, a spell of stormy and wintry weather—including hail and snow storms—set in, and, as a result, the soil is again in a wretched state. With the lengthening days and the increase of the sun's heat it ought not to be long before some progress can be made, and, in any case, there is no time lost as yet.

W. MCGUFFOG.

Balmac Gardens, Kirkeudbright.

CORRESPONDENCE.

Questions.—*Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly written on one side of the paper only, and addressed to the EDITOR of GARDENING, 63, Lincoln's Inn Fields, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, the name and address being added to each. As GARDENING has to be sent to press some days in advance of date, queries cannot always be replied to in the issue immediately following their receipt. We do not reply to queries by post.*

Naming plants.—*All who wish their plants to be rightly named should send fair examples of each—the stem, leaf, flower, or fruit. (Snippets of leaves and points of shoots are useless.) Not more than four plants should be sent in any one week by the same correspondent. Where more than one kind is sent they should be numbered. Of confusers the fruit should always be sent.*

Naming fruit.—*Several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. We can undertake to name only four varieties at a time.*

PLANTS AND FLOWERS.

Tuberose the second year (Tuberose).—Tuberose cannot be depended upon to flower in a satisfactory manner the second season, our climate not being favourable for the development of flowering bulbs. Yours will, in all probability, throw up plenty of foliage, and perhaps in a few weeks spikes, but, speaking generally, by far the most satisfactory way with Tuberose is to throw them away after flowering and obtain freshly-imported bulbs the next season. They may be bought at a very cheap rate.

Calceolarias in cold frames (A. G.).—As the plants are growing spindly they should be stopped; but this spindly growth must be because the glass lights have been kept too closely over them. It is now time to replant them in the frames, so that the plants may have more space to grow. They should be at least 4 inches asunder. If they are strong, as much as 6 inches may be allowed between each plant, so that they may have ample space to grow into nice bushy specimens by the end of May, when it is time to plant them out in the flower garden.

The Sweet Sultan (C.).—This hardy annual ought to succeed in a light sandy loam made fairly rich. An open and sunny position is best. Possibly your plants have been kept too long in the boxes before they were pricked out, or not kept sufficiently moist afterwards. It is always best to sow some seeds in the open ground, thinning the seedlings out to 4 inches or 5 inches asunder, and some in boxes. Then, if one lot fails, the other you have to fall back on. Treated as a hardy annual, we have always found the Sweet Sultan grow freely enough in any open garden soil.

Chrysanthemum leaves, injury to (G. Taylor).—The Chrysanthemum leaves you send have been attacked by the grubs of the *Marguerite Daisy-fly*, which, as you will observe, bore between the upper and the lower cuticles of the leaves, in which, if you examine them, you will find the grubs. The only way to destroy this insect is to pick off the infested leaves and burn them, or, if the attack has only commenced, to pinch the leaves where the grubs are. Syringing with an insecticide is of no use, as it would not reach the grubs, but if applied in good time it might prevent the flies laying their eggs on the leaves.

Repotting plants (Inquirer).—It is seldom wise to shake every particle of soil from about the roots of a plant, and even then when it is necessary to do so through its unsatisfactory behaviour. We presume you have fairly well-established examples, and if so, pot them out without disturbing the ball of soil more than necessary, just removing a little of the rougher particles. When the plants are entirely shaken out the roots are often much damaged, and thus progress is considerably impeded. Amateurs or beginners frequently come to grief over this matter. A reduction of the old ball of soil does not signify removal of every bit of soil.

Feeding greenhouse plants (Inquirer).—The best all-round nourishing liquid for the usual run of greenhouse pot plants is a weak infusion of either horse or sheep-droppings. It should be the colour of beef-tea and quite clear; if thick, a little lime will help to clear

it. For a change (and it should be remembered that plants, like human and other animals, always enjoy a varied diet), some weak and clear soot-water is very useful now and then, while a weak solution—3-oz. to the gallon—of sulphate of ammonia for flowering plants, and nitrate of soda for fine-foliated ones, is also excellent, as promoting root-action, and enabling the plants to more readily assimilate stronger food. The golden rule in giving liquid-manure is weak and often. Soot-water should be only just coloured—not inky, but almost clear, with a blackish tinge.

SHORT REPLIES.

V. S. Wrigley.—Under the circumstances, the only thing you can do is to net the Peas.—R. N. Ferrall.—Try dusting lime in the centres of the plants. Since you have found the ammonia effective, why not use this. You may use it now, and thus get rid of the slugs before the young growths are too far advanced.—Moor.—What you evidently want to do is to have the ground thoroughly trenched and give it a good dose of lime. Unless you do this you cannot expect to have any success, more especially with such roots as Carrots and Parsnips, which must have a good depth of soil to be of any value.—Inquirer.—Between 37 yards and 38 yards.—M. Grieve.—Regret we know of no other books dealing with the subject than those you have. A second-hand bookseller might have some second-hand books bearing on the subject.—D. W.—Write to the secretary, Mr. T. E. Henwood, 16, Hamilton-road, Reading, Berks.—John Moffat.—You should procure a copy of "Vines and Vine Culture," Barron, 13, Sutton Court-road, Chiswick, London, W., free for 5s. 6d.

NAMES OF PLANTS AND FRUITS.

Names of plants.—Murray T. Foster.—*Tillandsia Lindenii*.—M. L. J.—1, *Freesia refracta alba*; 2, *Primula obconica*; 3, *Iris reticulata*; 4, *Coleus thyrsoides*.—H. E. C.—1, *Andromeda japonica*; 2, *Skimmia japonica*; 3, *Deutzia gracilis*.—J.—1, *Selaginella kraussiana*; 2, *Adiantum concinnum latum*; 3, *Adiantum gracillimum*; 4, *Pteris cretica albolineata*.—Acacia.—1, *Acacia dealbata* (*Mimosa*).—J. W. B.—1, *Spiraea canescens*; 2, *Forsythia suspensa*; 3, *Juniperus sinensis*.—Mrs. C. Boulnois.—Your *Berberis* is evidently *B. japonica*, but it is difficult to say with any certainty from such a poor spray of flowers.

Names of fruits.—A. T.—Apples: 1, *Alfriston*; 2, *French Crab*; 3, *Newton Wonder*; 4, *Lane's Prince Albert*.—W. R. S.—Pears: 1, *Winter Nelis*; 2, *Josephine de Malines*; 3, *Nouvelle Fulvie*; 4, *Nec Plus Meuris*.

THOMPSON AND MORGAN, Ipswich.—*Catalogue of Choice Seeds, 1916.*

Name wanted of Rhododendron.—I wonder if any of your readers can tell me the name of a white hybrid arboreum, with maroon spots, that always flowers in February. I should judge it to be too rigid and upright for a caucasium hybrid. It is quite an old variety, as I remember large plants of it in Cornish gardens more than forty years ago. I thought it was called *gintatum pictum*, but am told I am wrong in this, as this is a later-flowering plant.—LANARTH.

OBITUARY.

MR. W. WELLS.

FREQVENTERS of horticultural shows, and lovers of Chrysanthemums in particular, will regret to hear of the death on February 28th of Mr. W. Wells, of the Chrysanthemum nurseries at Merstham, with which his name has been so long identified. He introduced many Chrysanthemums from America (which he visited some years ago) and Australia, and took the greatest interest in their development. Lately the firm has been turning its attention, with success, to Carnations. Much sympathy is felt for his family in their loss.

RIGHT TRAINING OF GARDENERS.

A FELLOW of the Royal Horticultural Society writes us as follows:—"In my experience the young men with the best certificates and diplomas are by far the worst gardeners. The system is wrong as applied to gardening. The Rev. Wolley-Dod was always very eloquent upon the subject, and matters have become much worse since his time. He used to say that the only true way of training a gardener was to start him in a good garden as soon as he left school and then the right way of working would become as second Nature, and an intelligent lad who took an interest in his work would learn more from observation than any lecturer could tell him. He would then, with advantage, read gardening books and papers without going in for the pernicious practice of cramming. Three years ago I had a fine example of a lad who brought enough papers to prove he was perfection. I never had a worse. He was everlastingly holding forth about analysis of soils, humic and ulmic acids, shrinkage and cohesion, humus and nitrates, and so forth, but they were only names to him, and he was out of his depth upon the first questioning. He had not the faintest idea of how to mix an ordinary compost for potting, and, as to weeding, he did not know a weed from a good seedling, and rooted up any amount of valuable self-sown seedlings around the parent plants. The only way was to give him pieces of Grass, Groundsel, and Dandelion, and tell him to pull up anything he found to match his patterns.

The colleges cannot teach knowledge of living plants, and the work which is made for purpose of demonstration is not like the routine demanded by Nature. Another mistake is that college lecturing and teaching will suit one district and be absolutely wrong in another. Here, again, is shown that observation is the golden rule. A garden at one end of the parish needs certain treatment, whereas in another at the opposite end success will be achieved by quite different methods, and the best of lectures can never equal the lessons taught by Nature.

One of the best outside gardeners I ever had could neither read nor write. He had started work in the garden at the age of nine and had stayed in the same place until his master's death, when he came to me. It was a treat to see his neat, careful work and his methodical way of setting about it. His knowledge of plants and

their ways used to surprise me. It had all been gained by observation and by always taking a profound interest in his work. He used to make his overtime long after he was 70. His work was all mapped out in his mind, and he was rarely at fault or behindhand in his operations. The disadvantage of not being able to write or read labels was more than compensated for by his unfailing memory of individual plants and their requirements, their position in the borders, and whether they should be propagated by root cuttings or pipings, and so forth.

I am not trying to prove that my man was such a good gardener because he had neither book learning nor college training, but what I do maintain is that a man can be a first-rate gardener without either the one or the other, provided he is interested in his work and has early training in the thing itself—the only training worth a thought. Reading or writing may not harm a man, it is the book teaching coming before the garden apprenticeship that does it." F. L.

NOTES OF THE WEEK.

Tulip Kauffmanniana flowered here in 1915 at the end of March or at the very beginning of April. The bulbs were replanted on December 20th. To-day (February 29th) I find one flower ready to open and several buds nearly as forward. *Antirrhinum Asarina*, in a very exposed position, has a number of buds which will apparently open with a little warmth and sunshine. This seldom flowers here before May.—E. CHARLES BUXTON, *Coed Derw, Bettws-y-Coed*.

Viburnums and grafting.—After reading Sir Herbert Maxwell's note of warning I hurried away to see my *Viburnums*, and there I found them nearly strangled by strong shoots of the *Viburnum* common in our hedgerows, and not therefore wanted in the garden. Nurserymen have much to answer for owing to their purblind ways of destroying valuable flowering shrubs and trees; I mean by unnatural ways of propagating without regard to the future life of the plant.—W.

Kaulfussia amelloides.—Readers who are unacquainted with this delightful little plant should certainly obtain a packet of seed. There are three varieties, a crimson, a white, and a blue, but I think the blue is far the best. Sown as an edging in March or April to a border of

annuals the effect is very pretty, for the blue flowers are very showy; or nice patches may be sown in the rock garden and will give a fine display. The plant only reaches a height of 6 inches, and may also be raised from seed sown in heat in the same manner as half-hardy annuals.—E. T. ELLIS, *Weetwood, Ecclesall, Sheffield*.

Freesia refracta alba major (syn. *F. Purity*).—Messrs. W. Mauger and Sons, Guernsey, send us two bunches of this handsome *Freesia*, the flowers of which are white with slight traces of lilac on the backs of the petals. In this variety the flowers are larger, the foliage also being longer and narrower than in the well-known *F. refracta alba*, but with the same yellow blotch and purple markings in the throat.

Oenothera Lamarckiana.—This fine, hardy biennial should be more frequently grown. Most readers are acquainted with the annual and the perennial Evening Primroses, but this one, being biennial, is somewhat neglected. The proper place for it is towards the back of a good mixed border, for it is rather a tall plant growing to a height of about 4 feet. Its fine yellow flowers make it a showy addition to the border. Seed may be sown at once in heat and the plants treated in the same way as Stocks and Asters, should flower in the autumn. They will, however, come into their full beauty next year.—E. T. ELLIS, *Weetwood, Ecclesall, Sheffield*.

Narcissus Brilliancy.—Messrs. R. H. Bath, Limited, Wisbech, exhibited this magnificent incomparabilis variety at both of the February meetings of the Royal Horticultural Society in company with Bath's Flame, which is of the same parentage, the old yellow trumpet sort, M. J. Berkeley, and a poetical variety. It is one of the many good things raised by Mr. Engleheart, and is in every way a great Daffodil, great in stature, in size, colour combination, and withal a good doer. Those who know the older sorts may get an idea of the beauty of this modern giant when I say that the flowers, poised at the summit of 2½ feet long stems, are each upwards of 4 inches across, perianth segments of an enhanced Frank Miles tone of yellow and golden cup of Sir Watkin size bordered by a heavy flounce of intense deep orange. To some extent this last appears to permeate the interior of the crown, and lightly suffusing with the gold, impart to this portion of the flower unusual life and warmth.

The appearing of Brilliancy in such good form in early February—it was in perfect condition on the 8th of that month—stamps it as a good forcing sort. Of the two, Brilliancy is the finer. Both, however, are excellent.—E. H. JENKINS.

Kennedyya monophylla rosea.—I enclose you a spray of a plant which received an Award of Merit from the Royal Horticultural Society on February 22nd under the name of *Kennedyya rosea*, but I am rather doubtful if this is correct, and I am sending a spray to Kew. The plants belong to the Countess of Cranbrook, who has a house near here. She brought them from her place in the south of France, where the plant grows freely out of doors, although it gets cut down in severe winters. She has them growing and flowering freely in a cool greenhouse here. There is also a very pretty purple form, *K. Comptoniana*.—R. C. NORCUTT, *Woodbridge*.

[A graceful twiner. In our cool-houses we do not make enough use of graceful Australian climbing plants as this, the correct name of which, according to the Kew authorities, is *Hardenbergia monophylla ovata*. It also does well at Abbotsbury, Dorchester.—Ed.]

Gaultheria Shallon.—Of the several species of *Gaultheria* this is the most generally useful. A native of Western N. America, it was originally introduced in 1826. It dislikes lime. It does well in loam and peat, preferring a rather light, permanently-moist soil. Mature plants are often about 3 feet high, although under certain conditions that height may be doubled. Branching freely and producing numerous sucker growths, it develops into a dense bush. During late spring and early summer numerous racemes of pinkish-white urn-shaped flowers are borne, these being succeeded by conspicuous blue-black fruits. Seeds are borne freely, but seedlings grow very slowly for a year or two. Another means of increase is division. To effect this, cut the plants well back in spring, divide them up into small sections, and pot each section separately into sandy peat and place in a close and warm frame until growing freely, when they may be planted out. If the sections when divided are planted out-of-doors they do not re-establish very quickly. *G. Shallon*, sometimes called by the common names of *Salal* or *Shallon*, gives good results in semi-shade and also in open places.—D.

Saxifraga dalmatica.—I do not know if there is authority for this as a specific name. It does not occur in Mr. Irving's useful book on Saxifrages, though it is occasionally met with in catalogues. The plant answering thereto is, however, a good one—virtually a *scardica* and not greatly removed—very little indeed—from those in circulation under the name *S. scardica obtusa*, of which there are two or three nearly related forms. That known as *Kestonensis* comes into the same category, but is earlier and therefore occupies a place apart. The subject of this note is white flowered, the parted, ovately-inclined petals, flower clusters, and short peduncles all suggestive of *scardica* relationship, as does also its time of flowering. Happily it blooms at a time—April—when it is welcome, and if there are others near akin of equal flower effect at the moment one never tires of an abundance of such things in due season. It is easily grown in gritty loam.—E. H. JENKINS.

The Winter Aconite poisonous.—At the present time, when round so many old country houses the ground is yellow with *Aconites* and when the plan of open-air

shelters for tuberculous cases is so much advocated, a word of warning may be given. A lady who spent all her days out of doors in a shelter had it placed in a wooded part of the garden carpeted by *Aconites*. During the month, when they were at their best and brightest, all went well, but after the flowers faded and seeds began to form she was taken seriously ill and every symptom of acute *Aconite* poisoning set in, with a fatal result in a few weeks. The doctor and a herbalist who were called in had no doubt it was from being surrounded by these flowers, the poison of which was most acute as the seeding process began, and, of course, this, acting on a delicate and consumptive person, had power it would not, perhaps, have on strong, healthy people. Certainly a wood in this country of arching trees overhead, sparsely clothed with brushwood and shrubs, is a lovely sight in the February sunlight, with its golden carpet. One regrets it should ever be found to be so dangerous.—MRS. PORTMAN DALTON, *Fillingham Castle, Lincoln*.

Pieris japonica.—Of the various species of *Pieris*, this is the best for general effect, for although *P. formosa* is a more imposing shrub when at its best, it is not hardy enough for general outdoor culture, and only gives really satisfactory results in the milder counties. *P. japonica*, however, thrives in many parts of the country and gives excellent results if treated as *Rhododendrons*—that is, grown in soil fairly free from lime, moist, without being water-logged, and sheltered from drying winds. Some people imagine that peat is necessary for the successful growth of this shrub, but such is not the case, although a little peat placed about the roots when planting is an advantage. An aid to success is shallow planting, placing a layer of 2 inches or 3 inches of leaf-mould over the surface of the ground to keep the roots moist and encourage surface-rooting. The white, pitcher-shaped flowers are borne in large, drooping panicles from the points of the shoots during March and April. The pendent inflorescences form a good distinguishing mark between this species and *P. floribunda* in which they are erect. The reddish colouring of the young leaves is another point in favour of this species.—D.

Plants from Holland in war time.—I used to get some hardy plants from Holland, mostly of a simple kind, that thrive best in the cool, peaty soils there, but my man, who has supplied me for many years, says he cannot send now owing to new rules as to registry of plants and fees. I wrote to M. Van Tubergen inquiring as to the question and he writes as follows:—

Up to now the only difficulty put into the way of importing bulbs, etc., from Holland into England is that *Lily of the Valley* and *Spiræas* (*Astilbe*) are strictly forbidden, the former on the ground that a portion of the same comes from Germany, although every Dutch grower himself cultivates these here and does not obtain them from anywhere else. Why *Astilbes* are forbidden is a mystery. These cannot be grown in Germany, but require our low-lying, moist ground to develop properly. Then there is the necessity of having an official declaration that what one sends is actually Dutch produce. No other formalities or regulations have as yet been issued, but in these times no one knows what the next day may bring. Postal packets can be sent as formerly without any difficulty.

FRUIT.

DESSERT CHERRIES FOR SMALL GARDENS.

DESSERT Cherries would certainly be far more satisfactory than poor varieties of Plums and Pears, for they are a favourite fruit, and, given a suitable selection, say in three or four varieties, are available for two months of the year. I do not, of course, imply that they should out the more profitable Plum and Pear in the best varieties, but rather that a few trees provide a nice variety. The great advantage of a few wall-trees over those grown in the open as standards or bushes is that they can be protected easily and cheaply, the blossom from frost and the fruit from birds. The blossom, being delicate, quickly succumbs to spring frost, and there is little chance of getting much ripe unprotected fruit if starlings and blackbirds are numerous. Where it is decided to plant a few trees a selection should be made of those varieties least susceptible to gumming and canker. This is important, especially in times like the present, when, if the natural soil is hardy to the liking of the Cherry, there is not much chance of getting a substitute in the way of expensive loam. Sorts whose growth, as a rule, keeps clean and healthy, arranged in the order of their ripening, are *Early Rivers*, *Governor Wood*, and *Florence*.

After frost, birds, and canker, the chief enemy of the dessert Cherry is black fly, and this has to be dealt with promptly if the foliage is to remain healthy. It curls up as soon as attacked, consequently, an occasional dipping of the shoots in a bowl of *Quassia* extract or some similar compound is much more effectual than syringing. Red spider is sometimes troublesome, and it is as well to give walls and every portion of the trees a thorough washing with the garden engine before the flowers begin to expand. E. B. S.

Hardwick.

OUTDOOR VINES.

Good advice was given a correspondent in a recent number of *GARDENING ILLUSTRATED* as to the various methods to be adopted for improving the condition of an outdoor Vine. It might still further have been improved by the suggestion of the substitution of a white Grape for a black, for whereas the best of the outdoor white Grapes, as *Stillward's Sweetwater*, will give a good return of very fair fruit, it is extremely difficult in the majority of seasons to keep the black generally represented by the variety known as *Black Cluster* free from mildew. I do not quite know why this should be, unless the skin of the black is more susceptible, but the difference is very marked, even in exactly similar soils and situations; indeed, I have noticed the difference when the two were growing practically side by side.

Grafting is not often practised on outdoor Vines, but if your correspondent has a few healthy shoots near the base of his Vine he might try the experiment if a similar number of pieces of the *Sweetwater*, well ripened, with plump, well-developed buds can be procured. There is not much difficulty in getting the graft to come away kindly if care is taken as to the union of bark, the tying, sufficient grafting-wax or clay, and that the Moss bound over this is kept damp. If the situation is exposed and the weather hot and dry it is advisable to hang up a bit of shading material until growth is well on the move. Care should be taken that such growth is firmly secured to the wall to avoid danger of breaking off. If a fair amount of growth is made by the end of the season it should

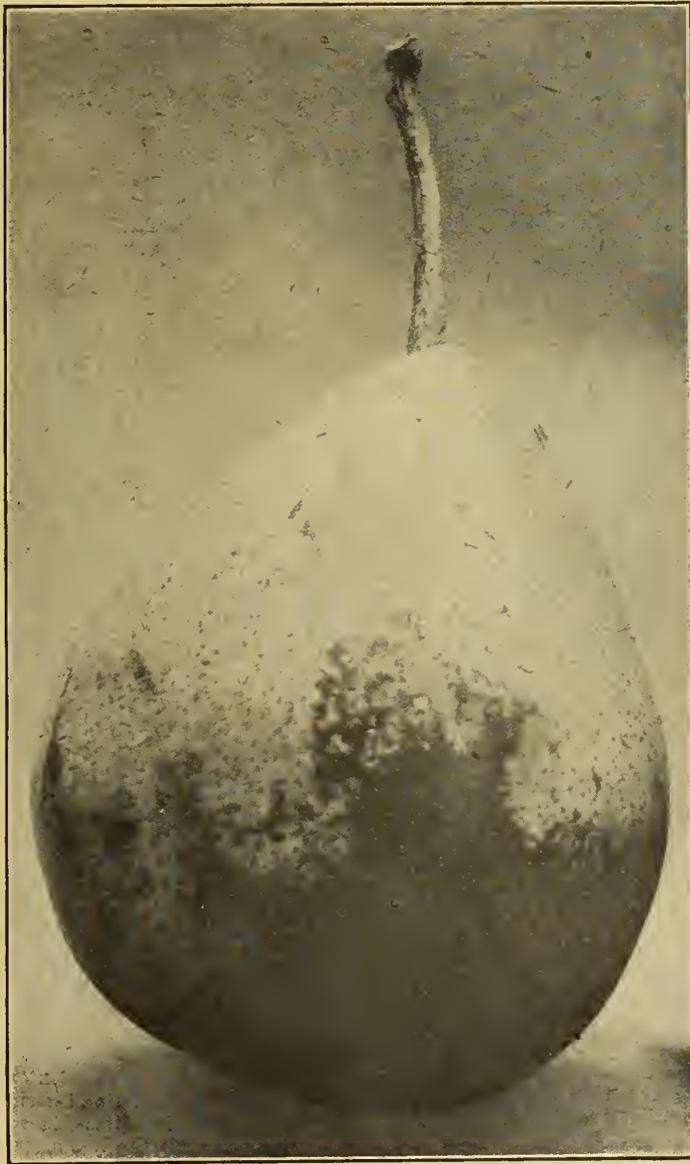

be headed back to well-ripened wood, and possibly a bunch or two of Grapes may be taken the following year, that is, if the buds break kindly and well. Failing grafting or inarching I should think young plants of Stillward's Sweetwater would prove in the end far more satisfactory than attempting to rejuvenate the old black.

E. B. S.

Hardwick.

PEAR MME. HUTIN.

In this we have one of the most distinct Pears in cultivation, and when a fruit is cut it creates a little surprise, as the flesh is quite pink. Another characteristic is

Pear Mme. Hutin. Gravetye, Sussex.

its exceptionally long stalk, sometimes over 4 inches in length. The fruit attains a good medium size (usually half a pound in weight), the skin of a pale yellow dashed with russet; flesh, soft, melting, and juicy; season, December and early January. I have only one tree, a five-branched cordon, growing on a wall facing south-west, in which position it is moderately vigorous, clean, and fertile. In autumn, when the leaves change colour, it is the most beautiful of a very large collection.

This Pear was raised in 1841 by M. Leon Leclere, from a pip of Leon Leclere de Laval.

CORDON PLUMS.

ALTHOUGH Apples and Pears are generally accepted as illustrating the system of cordon culture I think "C. R." (page 107) would find some of the Plums do equally well. There are, however, two points that seem essential towards securing success with Plums, the one to choose the very free-bearing sorts, and the other to give rather more liberal treatment than is usually meted out to wall-trees, bushes, and pyramids; more, in fact, as one would treat pot-trees. I do not mean an over-rich soil, but that the ground at planting time should be well done with a fair proportion of thoroughly decomposed manure

be almost entirely a question of summer pinching, and this, as with Pears, should be deferred until there is a slight sign of ripening. However, with some sorts, notably Early Prolific, the difficulty will be to get the wood.

The Plum has many enemies—aphis, red spider, and scale among the small insects, besides bullfinches and wasps, and in some districts it will doubtless be found advisable to net the trees against the birds, this being decidedly more effectual than dusting with lime and soot. The shoots of cordons are accessible, and aphis is easily dealt with, but red spider is a more insidious enemy, and must be taken in time, for injury to the foliage is detrimental to the trees. Given a clean start scale is not often troublesome if the foliage is kept in a healthy-growing state. If the trees are trained to wires great care should be taken that the wires are painted.

E. B.

Air roots on Vines.—When roots are emitted from the stems of Vines it is generally thought that there is something wrong with the roots. Generally speaking, this may safely be assumed, but there are circumstances under which these adventitious roots may be produced even when those in the border are healthy and under perfect control. The modern Grapewgrows are not so fond of atmospheric moisture as were those of former days. The latter were great advocates of evaporating-troughs; as a matter of fact, in the older type of vinery these were cast on the pipes. From the day the houses were closed until the time the Grapes began to colour, these troughs were kept full of water. Not only so, but in some cases liquid manure took the place of water after thinning was completed. In such houses, and under such conditions, air roots were freely produced, and such roots could not reasonably be held as proof that the real roots of the Vines were unhealthy. They were merely the result of environment, and it is quite possible that in many cases where these roots are present they are due to too much atmospheric moisture. No doubt many will have observed a similar tendency in the case of Tomatoes, which, if grown in a rather moist atmosphere, will develop roots, not only, like Vines, at the joints, but up the stem as well. In both cases, as soon as the ripening stage approaches and the atmosphere becomes drier on the reduction of moisture, the roots shrivel up and cease to grow.—K. BRIGHT.

Fruit-trees and root suckers.—Suckers are very troublesome sometimes, especially among Plum-trees when the land around or among the trees is under spade culture. The spade scrapes the roots, and from the injured surfaces suckers will spring in clusters. To get rid of these the soil must be cleared away, the suckers removed, and the origin carefully pared off with a sharp knife, or that portion of root shortened and removed altogether. In future a fork and hoe only should be used when other crops are planted among them. Suckers on the roots of other trees are not so troublesome as on Plums. The suckers of old Gooseberry-bushes, if neglected, appear round the base, and in preparing cuttings at this season all the buds, with the exception of three at the top of the cutting, should be cut clean away.

Fruit-trees over-pruned.—There is evidence everywhere of this, but thick planting is one cause. Give the trees more space to fill, and the pruner would be less needed. Wall trees are generally too crowded, and the same with espaliers and orchard planting, and if all young trees were lifted and the roots rearranged when about four years planted no root-pruning would be required.

with the loam; also a small percentage of bone-meal and mortar-rubbish. Then if the drainage is all right liquid stimulant can be supplied when necessary. It must be remembered that it is the nature of some of the Plums to produce a superabundance of fruit-buds at the expense of wood, and if one can make a fairly equal balance of the two, success is assured alike with healthy trees and good annual crops. Good sorts for the purpose are July and Transparent Gages, Jefferson's, Golden Drop, and Ickworth Imperatrice for dessert, and Early Prolific, Czar, Victoria, and Belle de Septembre for the kitchen. With the trees once established the pruning will

VEGETABLES.

NOTES AND REPLIES.

Early Turnips.—It is true one may sow earlier in some gardens than others, but my experience of Turnips is that nowhere can they be relied on to do well if sown before the first week of March. I do not now attempt to sow even in the first week, because from this sowing the percentage of edible roots is so small. In frames there is not the same tendency to bolt when sown in February as is the case when sown outdoors in early March. All who need Turnips at the earliest date would choose the Early Milan in white or purple-topped strains. The one is as good as the other in quality, but the white is more favoured as being the more attractive. When cooked there is no material difference between the white and the coloured forms. The Early Milan is distinctly the quickest to attain to edible size, and when it has thus developed, deterioration is just as rapid. For this reason small sowings should be the rule, and made as frequently as individual requirements demand. Netting against bird-raids must not be neglected or failure will result.—W. SIRUGNELL.

Tomatoes.—Plants raised from seed sown in October, and now growing in 6-inch pots, are showing flower, and will shortly be given their final potting, using 10-inch pots, and potting moderately firm. The plants will be placed in a house having a south aspect, and where a temperature of 60 degs. can be maintained at night, allowing a rise of 10 degs. by day, admitting air in favourable weather. When the flowers are ready for fertilisation pollen should be obtained from the best growers. Another sowing of approved varieties has been made for succession, and the pots containing the seeds placed in a temperature of 70 degs. As soon as the young plants appear they are placed as close to the glass as possible.—F. W. GALLOP.

Breaking up new land.—There are at least two ways of dealing with rough turf-land in preparing it for cultivation. One way is to trench in the rough surface and bury it deeply, and the other is to smother-burn the turf and rubbish and dig them in. Usually rough turf-land is badly infested with wireworm and other troublesome insects, which the burning will destroy. If the turf is trenched in it should be given a dressing of some soil fumigant or a mixture of salt and lime. The salt may be omitted from Potato-land, as it is apt to make the tubers waxy. The following are profitable Potatoes to plant during March and April:—First earlies: May Queen, Sharpe's Victor, Duke of York, and Midlothian Early. Later sorts: British Queen and King Edward VII. Great Scot, a new variety, has a great reputation as being immune from disease, especially black scab. Change of seed occasionally from north to south is useful.—E. H.

Immature seed Potatoes.—The fact that immature seed Potatoes give better results than those which have been fully ripened finds its way slowly among amateur cultivators of vegetables, and I have known of such Potatoes when found among other seed being rejected. Some people practise greening the tubers by exposure to the light after lifting them previous to their full maturity. I have tried this, and find that these greened, immature Potatoes yield excellent results.—S. A. M. D. [This "greening" is nothing new, as I can, as a boy, over fifty years ago, well remember my father—a gardener of the old school, lifting the tubers of a variety then largely grown under the name of Dalmahoy, selecting the seed tubers, and putting them into cutting-boxes which were stood along the sides of the garden walks. These tubers after a time became quite green and were then carefully stored in the boxes in a frost-proof shed, where they remained until wanted for planting.—T.]

GARDEN FOOD.

NOTES AND REPLIES.

An early Rhubarb.—For many years I had a considerable demand for early Rhubarb. Size was not wanted, but as early as possible, and the stalks had to be of a deep rich red colour. After repeated trials of all the best varieties I found the Early Scarlet the most reliable. This has a deep, rich colour, and, when cooked, is excellent. Such kinds as Royal Albert or Early Red are good, but these are later than the one named; also larger. Early Scarlet I found at times could not be got quite true to name. I have frequently had the one called Linnæus sent for it. Linnæus, though an excellent variety, is larger and of a pale pink colour, and was soon found fault with. For size such kinds as Daw's Champion and Myatt's Victoria would be preferred if earliness were not considered. For main-crop supplies The Sutton is an ideal variety. I have found it an excellent plan to sow seed of the Early Scarlet. If this is done one can very soon work up good forcing material. I also found I could get fairly reliable results from seed. As the seedlings soon show their colour in the stalk it is an easy matter to discard a pale or poor variety. Where roots can be secured by division at this season of the year it will be found, if this work is done early, say in March, good results are secured.—M. C. R.

Seakale in April and May.—We do not make as good use of this vegetable as it deserves, as grown naturally it gives little trouble, merely covering over for blanching. Kale grown for late work lasts for years. At the same time I find I get much better results by planting fresh stock, say every half-dozen years, and by so doing have very fine Kale. It is a mistake to cover the plants too early. I prefer to cover as late in February as possible, but much depends upon the season. If the plants have been well grown such aids as pots are not required. I find it quite sufficient to give the plants a little fresh lime over the crowns, this keeping slugs and worms at bay, and then a covering of fine coal-ashes is beneficial, and after that a quantity of soil from between the rows well banked up over the plants. Plenty of room is necessary between the rows to prevent damage to the roots. The Kale, when strong, has a tendency to push out at the side, hence the importance of plenty of soil when covering. In a warm spring I have often had to retard the growth by an extra covering of Bracken over the soil if it is light. In heavier land growth is less active. Kale grown thus will give good cutting material for from four to six weeks, and of fine quality also.—F. K.

Two good Peas.—To obtain a regular succession of Peas some little attention to varieties is necessary. If Pilot and The Duchess be sown on the same date a succession will be assured. The former is too well known to call for comment, but the good qualities of The Duchess do not seem to be so generally known. Between 5 feet and 6 feet in height, the variety carries a very heavy crop of large pods, each containing at the least nine Peas—often more. The flavour is all that can be desired, and from the fine shape of the pods The Duchess is not without value as an exhibition sort. Personally, I prefer it, for this purpose, to the Gladstone Pea.—Scot.

Potato Langworthy.—I am quite in accord with you respecting the Langworthy. I wrote you recommending it in the early part of 1913; and I find a note

in your paper of January 18, 1913. Unfortunately it does not crop well enough to grow for market, and I have not been able to get enough this year.—HERBERT MALIN.

Solid Red Celery.—I was pleased to see "Kirk" mention Major Clarke's Solid Red Celery, as it was always considered one of the best. Sulham Prize Pink was a more robust grower and a splendid keeper, and a good early white was the Sandringham White. Those three varieties thirty years ago were largely grown, and I have no doubt they are to be found now under other names, as they were too good to disappear altogether.—E. H.

A good Potato for baking.—Questions have been asked in GARDENING ILLUSTRATED as to good baking Potatoes. I find Arran Chief bakes splendidly.—K. M. H., Surrey.

RHUBARB DISHES.

RHUBARB properly cooked is one of the most useful of "pie-plants," but, unfortunately, it is usually swamped with water and stewed, very seldom being prepared in any other manner. Stewed Rhubarb is very nice, but no water should ever be used with the stalks. If very tender they should be washed, cut into inch lengths, dropped into water, and then put into a stewing-jar while still wet, sufficient sugar added, and the jar placed in a moderate oven until the stalks are tender. Rhubarb stewed in this way is far nicer than when water is added. Two or three slices of Lemon will vary the flavour. Many people cannot eat pastry, but a delicious

RHUBARB-TART can be made without pastry. Fill a pie-dish very full of Rhubarb cut into short lengths, sprinkle sufficient sugar over, add a shred or two of Lemon-peel and three tablespoonfuls of water. Take sufficient fine breadcrumbs to cover the Rhubarb, and mix with them a little sugar and a tiny pinch of powdered cinnamon. Spread the crumbs over the top of the Rhubarb. Sprinkle a little dissolved butter over the top and bake in a moderate oven until the top of the crumbs is nicely browned. This tart can be eaten with custard or whipped cream, but it is very nice without any accompaniment.

RHUBARB BREAD-AND-BUTTER PUDDING is another nice way of cooking Rhubarb for the children's dinner. Stew some Rhubarb, as in the preceding recipe, and fill a deep pie-dish with layers of bread and butter and stewed Rhubarb. There should be sufficient juice to just soak the bread. Bake in a moderate oven until slightly browned on top. Serve either hot or cold.

RHUBARB FOOL is another dainty way of serving this "pie-plant." Cut the Rhubarb into lengths and stew without water with sufficient sugar to sweeten. Beat the Rhubarb to a purée and set aside to get cold. There should be a pint of the purée. Place a pint of milk over the fire, sweeten to taste, and add a small piece of Lemon-peel. When it boils remove from the fire, take out the Lemon-peel, and stir in a well-beaten egg. Beat for ten minutes, then pour from one jug to another until the thin custard is cool. When cold mix gently with the Rhubarb purée and place the mixture in a deep glass dish. Grate a little nutmeg on top and serve very cold.

RHUBARB PASTY is quite an unusual way of cooking Rhubarb. Take a pound of Rhubarb and cut it into very small pieces, place in a jar with two heaped tablespoonfuls of Currants and an ounce of candied Lemon-peel chopped finely. Add enough sugar to sweeten and place in an oven until the Rhubarb is tender. Line a cooking plate with a layer of nice flaky pastry. Add the Rhubarb mixture, and cover with pastry. Decorate the edges and brush over the top with a little milk. Bake in a hot oven until the pastry is nicely browned and well cooked. Serve either hot or cold. H. THORBURN-CLARKE.

TREES AND SHRUBS.

THE TULIP-TREE.

(*LIRIODENDRON TULIPIFERUM*).

THE accompanying illustration of a Tulip Tree growing at Woolbeding, Surrey, directs attention to one of the most ornamental and interesting of deciduous trees suitable for garden decoration. A native of North America, it has long been an

as Perthshire. Good examples 40 feet to 50 feet or more high have been noted in the Lowlands of Scotland, although about Edinburgh it does not grow really well; those in Perthshire, however, are of average development.

It is as a tree for the Midlands and South of England, however, that it makes special claims upon our attention, and in those parts it can be planted freely. In America it sometimes grows between 150 feet and 180 feet in height, with a trunk

quantities it is probable that the tree might be planted successfully for commercial purposes. The wood is imported under the names of Basswood, White Poplar, Yellow Poplar, and Canary White-wood, and timber grown in this country compares well with that from America. The only drawback to its wide cultivation as a forest tree is the supply of seed, for a very small percentage of that produced here is fertile, and seeds would need to be imported. Until 1875 it was considered to

The Tulip-tree (Liriodendron tulipiferum) at Woolbeding, Surrey.

occupant of our gardens, for in 1688 it was grown in the famous garden of Bishop Compton at Fulham, and in the following century various references were made in old gardening works to well-grown examples in the neighbourhood of London and in other parts of the southern counties. But it is not only in the south that it is a success, for it gives excellent results in the Midlands and in some parts of the North of England, whilst north of the Tweed it thrives in the milder localities and in sheltered positions as far north

5 feet in diameter. Here it does not grow so tall, although there is plenty of specimens between 80 feet and 110 feet high with trunks between 3 feet and 4 feet in diameter. It is not very particular regarding soil, but perhaps attains the best proportions when planted in good, deep loam that is permanently moist without being water-logged. A little peat or leaf-mould placed about the roots at planting time is appreciated by the tree, although they are not really necessary. As the timber is useful and imported in large

be the only species of the genus, but in that year Mr. Shearer discovered a second species,

L. CHINENSE, in China. Mr. Maries reported it again in 1878, and Prof. Henry also collected specimens. It, however, remained for Mr. E. H. Wilson to introduce the tree, he sending seeds to Messrs. Veitch in 1901 from Hupeh. This species is very similar in appearance to the older tree. Prof. Henry considers that the leaves are more glaucous and the flowers, which have not yet been borne here, are said to be

greenish and smaller than those of the American tree. It can be grafted upon stocks of the common Tulip Tree and grows very freely. D.

NOTES AND REPLIES.

Planting bed in exposed position.—I have in front of the house five very large beds. Four are filled, one with Laurustinus, one with Berberis, one with the common St. John's Wort, and the fourth with the purple Heather, all of which are very effective and suitable. The beds are in a very exposed position, and everything is kept very dwarf on account of the wind. What can I put into the fifth bed? It is very large, and, therefore, whatever is used must not be costly.—E. M. T.

[Without seeing the spot, we should keep the whole set of beds for hardy Heaths. There are so many good kinds now, even flowering in mid-winter. A few dwarf evergreens may be grouped with them, like the Menziesias, Partridge Berry (dwarf), Daphne Mezereum, the dwarf Japanese Box, and Blaeberry, with some hardy flowers between them, as Scarlet Windflower (*Anemone fulgens*), Spotted Lungwort, *Campanula glomerata*, and Barrenwort (*Epimedium*).—Ed.]

Shrubs for bleak aspect.—My house, with a strip of garden, faces west, and the wind from that quarter is abominable here. What shrubs, 6 feet to 8 feet high, evergreen, and as far as possible ornamental, would form the best shelter? They must be quite hardy. What would be suitable flowering shrubs to grow on the sheltered side of these?—WYNDALE.

[The following should answer:—The true Laurel (syn. Sweet Bay), hardy, we think, in your district; Laurustinus, several kinds; any form of the common Box and the Minorca Box, Savin, double Furze and Hollies, a fine variety of which may be seen in any good nursery, such as that of Fisher, Son, and Sibray, at Sheffield. The soil and growth in your district will tell you if the Rhododendron will thrive.—Ed.]

Stachyurus praecox.—Although this shrub has been in cultivation in a few places for many years, it is not well known. It grows 8 feet or more high in its native country—Japan—and probably it will attain similar dimensions here, although plants growing in the open are inclined to develop laterally rather than in height. The young wood, of dark red hue, is conspicuous during winter by reason of the unopened flower-buds which are formed in autumn and remain unopened until the first warm days of the New Year. They then develop rapidly, and during February or early March, according to the weather, the yellow flowers are freely borne in drooping racemes, each 3 inches to 4 inches long, from almost every bud of the previous year's wood. At Kew a fine plant, about 3 feet high and 4 feet across, was covered with flowers during the first week of February, two or three weeks in advance of the normal time. The flowers and young shoots are liable to injury if very cold weather is experienced. Plant in a position sheltered from cold winds, in light loamy soil containing a little peat or leaf-mould, or in cold districts it might be trained to a wall. One or two new species have been introduced from China within recent years, but they do not appear to be any improvement on the Japanese shrub.—W. K.

Hollies from seed (A. G. R.).—The berries are gathered when ripe, mixed with double their bulk of dry sand, and turned over every month, which hastens the decomposition of the fleshy portion. The seeds are thus stored in a heap in a shady spot outdoors till the following autumn, when they are sown in rich, light soil, covered about a ¼ inch deep, and a few Spruce boughs laid over the bed till the seedlings appear, which will be in May, and only then a few, a succession being kept up till the next spring. Leave till the following autumn before transplanting. You may also store the seed, mixed with sand, in a flower-pot, and bury it till the autumn, sowing it then in boxes or pans in an ordinary cold-frame.

PLANTS AND FLOWERS.

INDOOR PLANTS.

RAISING GLOXINIAS FROM SEED.

If seed is sown at the present time, and the resulting plants grown on afterwards without a check, excellent specimens can be obtained which will yield a fine display of bloom in late summer and autumn. Where Gloxinias are appreciated this is a good method of forming the nucleus of a collection, as if seed of a good strain is purchased plants yielding flowers in a great variety of lovely colours may be had. The best can then be selected and saved for growing again the following year. This is also the best way of keeping stock up to date. A packet of seed will, if properly sown, yield a large number of plants. A pan is better than a pot in which to sow. This should be well drained and filled to within 1 inch of the rim with a mixture of peat, loam, and leaf-mould, with enough sand added to render it porous. On this a ½-inch layer of the same material passed through a fine sieve is placed and made firm. The pan is then immersed not quite up to the rim in a bucket filled with tepid water, where it is allowed to remain until the compost has become thoroughly soaked. It is then removed, and after draining for an hour or so the seed is distributed as evenly as possible over the surface of the soil, and is then lightly covered with silver sand. After covering with a sheet of glass with paper on top, both to prevent the surface drying too quickly and to favour quick germination, the pan is then stood on a shelf in the stove. When the condition of the soil indicates that a further supply of moisture is required the pan is partly immersed in tepid water as before, which method is preferable to watering with a rosed can, as no displacement of the seed can then occur.

G. P. K.

HIMALAYAN RHODODENDRONS.

I WANT to increase my stock of large-flowering Himalayan Rhododendrons. The original unnamed plants are giving out through old age. I enclose a blossom to show the largest kind. They are all grafted plants. Would you kindly tell me on what stock to graft them? Would they do grafted on the common Rhododendron ponticum?—ROSAMOND A. CHRISTIE.

[The enclosed bloom of Himalayan Rhododendron is too much shrivelled to name with any degree of certainty, but it appears to be Countess of Haddington, a hybrid between *R. ciliatum* and *R. Dalhousiae*. These Rhododendrons are grafted on to seedling stocks of some allied kinds, while cuttings are not difficult to root where proper structures and appliances such as are to be found in trade establishments exist. Failing a low, close structure containing propagating cases, and wanting in practical experience, we fear that you are not likely to succeed. As a stock to these Rhododendrons plants of *R. ponticum* would be useless. Most of these Himalayan Rhododendrons and their hybrids seed freely, and young plants can be readily raised therefrom. The seeds should be sown in well-drained pans of sandy peat, placed in a greenhouse, and kept shaded till germination takes place. Of course, they will take four years to five years, or even more, before they flower.

The grafting of greenhouse Azaleas is practically in the hands of the Belgians. The stocks employed are two varieties—namely, *A. concinna* and *A. phoenicea*. The cuttings are obtained* from the soft shoots pushed up at the base of the young grafted plants. They are dibbled into pots of sandy soil and placed in a close

propagating case in a warm house. When rooted they are potted off, and when about the size of a stout straw are grafted. This operation is carried out towards the end of the summer, when they must be kept quite close till a union is complete. These Azaleas may also be struck from cuttings of the young shoots taken in the spring, inserted very firmly into well-drained pots of sandy peat, and placed in a close, warm structure till they root. As there is very little chance of success in your grafting Rhododendrons and Azaleas we would suggest that it would be more satisfactory to purchase the plants required from a nurseryman.]

NOTES AND REPLIES.

Propagating from highly-fed plants.—

At the present day, owing to the fact that highly stimulating manures are put up in such convenient forms, they are used to a greater extent than ever. This extensive use can be defended when the object is to get as great a display as possible from a plant which will, when its flowers are over, be thrown away. Woe-betide the individual, however, who depends upon such plants for propagating, as though fine fat shoots may be available, they take a long time to root, and many fail altogether to strike. Even when this takes place they do not grow away with the same freedom as cuttings taken from plants that have been grown under more rational conditions. After an experience of many years of propagating I always prefer cuttings taken from shoots of medium vigour to the very strong ones. Of course, when the aim is to make as many as possible from a particular plant one is tempted to take both stronger and weaker shoots than are desirable. In all cases, but more especially to the amateur, I should say avoid, if possible, taking cuttings from plants that have been fed with stimulating manures. In the case of these last it will be often found that though the growth may be strong, the root system is more scanty than in the case of a plant grown in a rational manner.—K. R. W.

Balsams.—Among the older greenhouse plants which have been ousted by more recent introductions, Balsams were at one time prime favourites. In these days, when labour is scarce, and easily-managed plants will, for a time, be preferred, a packet or two of Balsams might very well be sown. Seeds sown in April will readily germinate, and if kept near the glass and moved steadily on as necessary, good pieces over 2 feet in height, and covered with bloom, can be had in 8-inch pots during August. These last for some considerable time in good condition. The season of flowering can be prolonged by successional sowings.—KIRK.

Camellias.—The flower-buds of Camellias planted under a south-west wall are beginning to show colour. Camellias are much hardier than is generally supposed. The chief thing to guard against is rough winds, which bruise the flowers. A west or south-west aspect is the best, and if the site is a well-drained slope, so much the better. A periodical top-dressing of roughly-chopped fibrous loam, mixed with a little peat and leaf-mould, is very beneficial. When severe frosts are anticipated mats are laid over the plants at night.—F. W. GALLOP.

Schizanthus Wisetonensis.—A good batch of plants for flowering early has been shifted into 6-inch pots. These were in the right condition for potting, there being just a sufficiency of roots without anything approaching a root-bound condition. Consequently, they should give a good account of themselves when the flowering stage is reached. Until growth becomes further advanced they will remain on a shelf close to the roof in a greenhouse.—G. P. K.

OUTDOOR PLANTS.

LEUCOJUM VERNUM CARPATHICUM (SPRING SNOWFLAKE).

THERE are few more attractive early spring flowers than the Snowflake here shown. Soon after Christmas the buds, pushing through some evergreen undergrowth, are charming. The Snowflakes are admirably adapted for growing through permanent dwarf edgings, or wherever a dwarf groundwork can be provided, as this shows them at their best. They appear quite at home in any position, and any soil suits them unless it is a very dry one. The white and slightly fragrant flowers, usually produced in pairs, are prettily tipped with green, and occasionally canary-yellow, which serves to enhance their beauty.

This form must not be confused with the Summer Snowflake (*L. æstivum*), the type of which is poor in comparison and grows much taller. The best of the Summer Snowflakes I have yet seen is a variety of the above called Gravetye

able to give a light top-dressing of short manure and roll it shortly afterwards, as the thin coat of manure retains the moisture in the soil and is very helpful.—E. H.

AMONG THE HARDY FLOWERS.

WATERING SEEDLINGS IN POTS.—My amateur friends complain of the difficulty they experience in raising hardy plants from seeds sown in pots. Their main complaint is that the seedlings damp off, and that they lose a great number in that way. Much of the trouble arises through injudicious watering. If a thorough soaking is given so that the water passes right through the pot and is carried away by ample drainage there is little fear of the seedlings damping off, especially if they have a sufficient supply of light and air to keep them from becoming drawn. The danger appears to lie in the surface of the soil being damp and that below too dry. I always water the seedlings by dipping the pots in water and allowing it to rise through the surface of the soil. If this is properly done the cases of damping-off are

bought in on the strength of its being, as the list said, "like a glorified White Heather." It may be so in some places, but with me in a moderate climate and in a warm, sunny place in dry soil it has not flowered. Is it a shy bloomer? Perhaps I may not be giving it the necessary treatment, but most of the Stonecrops flourish and flower in similar places to that in which *Sedum primuloides* is planted. It is a comparatively new Stonecrop, and it is very disappointing to pay a higher price than usual for a Stonecrop and to discover that it is a shy bloomer.

AN AMATEUR OF HARDY FLOWERS.

TRANSPLANTING CHRISTMAS ROSES.

REFERRING to Sir Herbert Maxwell's note as to the best time for the above work I may remind him that the treatment prescribed by me at page 62 was given with the full knowledge that in the northern districts of England a certain measure of success attended the planting of Christmas Roses in March, the same period adopted by himself. I learnt that way from my father as a youth, and in a midland county, too, where the Christmas Rose generally was a considerable success. Since that time I have learnt the value of September planting, hence speak with a knowledge of both systems. Moreover, my advocacy is based on the knowledge of root-production in these plants, which cannot lightly be disposed of, much less gain-said, and only those who adopt those principles are likely to obtain the fullest measure of success, with which is incorporated the earliest flower harvest as a return for timely planting.

Sir Herbert Maxwell says: "If we in the west were to disturb Hellebores in September we should run the risk of their being seriously injured by winter wet." Is this, may I ask, a surmise, or actual experience? If the former, it is, for present purposes, valueless; if the latter, I would make "September" read "August," and so, getting in advance of the period of basal-root production in these plants, embrace it and its advantages in all its fulness. Sir Herbert Maxwell evidently does well with the Christmas Rose, assisted, doubtless, by the humid conditions by which he is surrounded. All the same, I do not hesitate to assure him that he may obtain the fullest measure of his present success by observing in his own case the natural period of basal-root production—an annual occurrence in this section of the Hellebores—and be guided by what it dictates. I have no desire to appear dogmatic in the case, my one aim being to demonstrate to growers generally the need for observing certain rules if they would succeed with one of the most precious winter flowers we possess. The fact that *H. niger altifolius* begins flowering in October does not affect the point at issue. Christmas Roses well done do not need replanting each year, and the few flowers sacrificed in the season of planting—if sacrificed they be—would be repaid by the far greater yield of the years to follow—the product of planting at the right time.

Mr. F. W. Gallop thinks I should have found it "impossible" to divide the plants he referred to "without first washing out the soil." He is mistaken. A couple of small hand-forks placed back to back and thrust to their full depth into the plant—the example having been first laid on its side—will successfully wrench in half any ordinary-sized clump, and a repetition or two, as necessary, will reduce it to any size you will. It is, therefore, not "impossible," it is simplicity itself. No method of division is more

The Spring Snowflake (Leucojum vernum carpathicum).

Giant, which, with me, grows 3 feet high and bears several flowers on stout stems. There is also the Autumn Snowflake (*L. autumnale*), a dainty little species rarely more than 4 inches or 5 inches high and bearing, in autumn, white flowers with pink spots. E. M.

Sowing down a lawn.—Good turf free from weeds and their seeds is scarce now, and expensive, and a good lawn can be made from seeds. The ground should be trenched or dug over now, and if necessary manured. Very wet land may require a few drains, 2 feet deep or so, if an outfall can be obtained for the water, and this can generally be found near. It is important that the soil be prepared in good time so that the weeds can be cleared by hoeing before the Grass seeds are sown. The ground for a tennis-lawn should be made perfectly level. A good seed firm can supply the right kind of seeds if they are told the kind of soil. Do not mix Clover with the Grass seeds, as tennis players say it is more difficult to obtain a firm footing. During a showery time in April the seeds soon germinate, but when sown later I have found it advis-

reduced to a minimum. Too thick sowing is also a serious source of damping-off. It is astonishing how quickly seedlings will succumb to this damping-off. Watering carefully appears to me to be one of the prime factors in preventing seedlings damping-off.

COVERING SEEDS OF HARDY FLOWERS.—Many of us have had some difficulty in deciding the depth to which seeds, especially the small ones, should be covered with soil. My experience is in favour of a slight covering of fine soil. Even if this is merely a sprinkling, it is, I think, safer than leaving them uncovered. This covering is especially advisable with seeds which frequently lie a long time before germinating. Hardy Primulas come under this category, and I find that if the seeds are not slightly covered there is not such a good return from later seedlings. In the case of *Primula japonica* the seeds germinate freely if they are not covered with soil, only a sheet of glass and a piece of paper being laid over the pot until the first seedlings have germinated.

SEDUM PRIMULOIDES.—May I ask the experience of others as to the flowering or non-flowering of *Sedum primuloides*? I

expeditious, none fraught with so little loss. What is true of the hand-forks with a plant of ordinary size is equally true of the flat-tined garden fork when dealing with giant clumps of anything herbaceous—yard-wide stools of Funkia, Kniphofia, Pampas Grass, Day Lily, or what you will. For all such the garden fork is excellent, easily displacing chopper and spade, murderous weapons both, ideal for hacking plants to pieces, but for rational division quite useless. E. H. JENKINS.

GROWING VIOLETS.

Will anyone kindly tell me how to grow Violets out-of-doors? How should the bed be made and what is the best aspect? What is the proper time for planting? Kindly name the hardest kinds for a very cold part of North Wales?—HAFOD.

[Runners should be put in every year, April being the best month for doing this. In the case of very light soil, which always suffers if the summer is very dry, a little shade is beneficial. On holding soils Violets are just as well, if not better, planted in the open. This applies to double or single Violets intended for frames or outdoor culture only. Ground for Violets must be of good quality, and be well prepared by trenching or deep digging, with plenty of manure added, and, if possible, some leaf-mould. The single varieties, on account of their stronger growth, require more room than do the double forms. Single varieties of the modern kinds, such as the Princess of Wales, flower freely on the runners which issue from the parent plant, and for this reason such runners may be left. The double varieties, on the contrary, must have the runners removed, so as to strengthen the crowns which give the finest blooms. By the end of October the plants will have completed their growth, and can then, when required, be put into their winter quarters. The frame should be in a sunny position, preferably facing south, the soil should be rather light, and the plants, when placed therein, should come to within 6 inches of the glass. Give a good watering to settle the earth round the roots, and little or no more water will be required until March, or even later. In frosty weather the glass should be covered with mats or straw, but except in a time of sharp frost air must be left on at night. It is only free ventilation that will keep down damp, and the plants should be looked over occasionally and decaying leaves removed. If any symptoms of mildew appear dust the undersides of the leaves with sulphur. Good doubles are Mrs. J. J. Astor, De Parme, Comte de Brazza (white), and Marie Louise. Good singles are Princess of Wales, La France, and Admiral Avellan.]

THE BROAD-LEAVED ROCKFOILS (MEGASÆA).

NEVER have I seen these plants so fine as this year. At the end of January and in the early days of February the clusters of Peach-coloured flowers were borne on stout stems from a foot to 18 inches in height.

The pale colour of the flowers of *M. crassifolia* under artificial light is beautiful, the yellow stamens, when fully developed, enhancing their beauty when cut. The flowers are very lasting. With one or two exceptions the plants are quite hardy, and will thrive under almost any conditions. During the autumn and winter their bold, leathery leaves develop rich tints of red, crimson, and yellow, for which reason alone they are well worth growing. To secure this fine colour in winter they should be planted in broad lines as edgings, as foregrounds to banks of evergreen shrubs, or in groups on

sunny mounds, where the poorer the soil the richer will be the colour of the leaves. The best for this purpose are *M. Stracheyi* and *M. purpurascens*, to which might be added several hybrids. The best results as to flowering are obtained where the plants have enjoyed a little shade during the summer, but this robs the leaves of much of their winter colouring.

Several species are known, these including deep purple, rose, and peach coloured forms, while some of the hybrids are almost pure white, and a few are of a smaller and less spreading character. A group of these plants at the foot of a large Japanese Cherry flowers very early. They are also used in the manner suggested above; also in recesses which occur among trees and shrubs, and naturalised in Grass which is somewhat overhung with trees.

In the last case they practically take care of themselves. It is rather exceptional to see them used in this way, and I would advise anyone having a surplus stock not to destroy them, but provide a space which is not frequently mown.

The following are some good kinds:—*M. cordifolia*, *M. cordifolia purpurea*, *M. crassifolia*, *M. ligulata*, *M. Stracheyi*, *M. purpurascens*, *M. Milesi*, *M. yunnanensis*, *M. Brilliant*, and *M. Corallie*. *M. ciliata alba* is a lovely, almost white flowered form, but not quite so hardy as those just mentioned. E. M.

NOTES AND REPLIES.

Saxifraga hybrids.—In the book on Saxifrages by Irving and Malby two hybrids are named of *Burseriana* origin—parentage same, viz., *S. Burseriana macrantha* and *S. Frederici Augusti*, and both coming from Kew. One is called *S. Burseriana rosea*, the other *S. B. kewensis*. Can you tell me if either is the one called *S. Irvingi*, or is that yet another hybrid of same source?—D.

[It is the one named "*S. Burseriana rosea*" in "*Saxifrages*" that has now been definitely named *S. x. Irvingi*. Strange to say this pretty hybrid, although only a year or two old, has already received three distinct names—viz., *S. B. elegans* originally, next *S. B. rosea*, as more descriptive of the colour, and, finally, *S. Irvingi*, under which name it was certificated and has passed into commerce. The defects of the two earliest names, making the hybrid a mere varietal form of *Burseriana*, being obvious, created the necessity for a third, hence the final name, *S. Irvingi*. Fortunately, as it has only been distributed, we believe, under the last name, no confusion is likely to arise, while the name "*S. Burseriana rosea*" will doubtless be replaced by *S. Irvingi* in the next edition of the useful book referred to. *S. x. Kewensis*, the other produce of the cross, has greater affinity with *S. Frederici Augusti*, its leaf character, much taller forked stems, red bracts and flowers, all leaning strongly to it, to say nothing of its constituting a link of the greatest possible value in the chain of circumstantial evidence as to the hybrid origin of both, the twain appearing in a batch of seedlings of *S. Burseriana macrantha* raised at Kew.]

Groundwork for Rose beds.—As a reader of your paper for nearly thirty years, may I ask your kind assistance in giving me the names of what you would consider the most satisfactory plant to carpet a Rose bed? I have three large ones, and for a great part of the year they are not objects of beauty. Would you approve of dwarf Heath? Preference should, I think, be given to some plant whose colour would not clash with the Roses when in bloom.—E. M. T.

[Begin with Tufted Pansies of delicate colours—mauve, lilac, yellow, blue, and white. You can hardly go wrong with these until the soil gets tired of them, when some other dwarf hardy plants may be tried.—Ed.]

Fasciation in the white Martagon Lily.—It does not appear to be very widely

known that some stocks of the White Martagon Lily are specially liable to the deformity known as fasciation. This fasciation is annoying, as the results are not only flattened stems, but flowers in an ungainly mass. The extent of the fasciation and deformity of the inflorescence vary, but it is annoying to receive bulbs which produce this fasciation. I am satisfied that this fasciated form occurs very largely in certain stocks. I know gardens in which what one may call the good form has been established for years and has never given fasciated stems, whereas some purchased bulbs have, for years, come with a large proportion of fasciated growths annually. I can recollect a nursery in which a row of *L. Martagon album*, imported from Holland the previous year and comprising a hundred or so of bulbs, gave hardly any perfect stems and flowers. Is this a case of the deformity being permanent in the bulb and transmitted by means of propagating the Lily from scales or offsets?—S. A.

Hotbeds.—Owing to the increasing scarcity of manure it will be necessary to employ a larger admixture of leaves than is usual, but as hotbeds, at this time, are principally used for the pricking off of early vegetable seedlings, the matter is of less consequence. A deep two-sash pit will be got ready immediately, the first brisk heat being utilised for starting pots of seeds. The value of such a hotbed is considerable, for after vegetable seedlings are fit to go out, the bed is again used for half-hardy annuals—Stocks, Asters, Lobelia, Antirrhinums, and the like. After these go out, with the increase of solar heat and with a little freshening up of the material the pit is used for growing Cucumbers during the summer and autumn.

Sweet Peas.—A sowing will be made in the open about this date on ground that was well prepared in the autumn. These will succeed the plants raised from seed sown in pots under glass, and which will be planted out as soon as the weather is favourable. A common mistake in growing Sweet Peas is sowing too thickly. Let the seeds be placed 3 inches apart in drills 3 inches deep. To fill up gaps caused by birds, mice, or slugs, have a nursery bed in which sow a dozen seeds of each variety, labelling each group, 2 inches apart each way, and transplant when about 3 inches high into the vacant positions. As soon as the seedlings show above the soil, which will be in a little over a month from the time of sowing, dust them heavily with soot.

Statice Suworowi alba.—Many who are well acquainted with *S. Suworowi* may not know the white form, which is of comparatively recent origin. *S. S. alba* is a hardy annual, and can be used effectively in beds or borders; but it is especially suitable for pot culture. The habit of the plant is dwarf and compact, its pure-white sprays being very freely produced. These when grown under glass are much finer than those from plants in the open, and are, consequently, much more valuable for cutting. Considering the ease with which this and other annual Statice can be grown for greenhouse decoration, many might with advantage give these and similar things a trial during the present season.

Muscari botryoides.—This (March 1st) is showing its blue spikes freely in a warm border fronting a Peach case. The soil is of excellent quality, and the exposure all that can be desired. It is, no doubt, chiefly attributable to these factors that the bulbs increase so freely. A number of years ago there were but a few bulbs, now there is a colony almost 2 feet in diameter in this particular place, and it grows in size and attractiveness annually.

Manuring Ferns.—About two weeks ago I noticed an article on Ferns in which the writer said Ferns would not stand either solid or liquid manures. All I can say is, I always manure my hardy Ferns with both liquid and solid manures, and have, in consequence, had fronds of *Scolopendrium vulgare* nearly 3 feet long and about 3½ inches across.—C. D. LANGWORTHY, Claygate, Surrey.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM MARCH 2ND.—*Berberis* (in variety), *Daphnes* (in variety), *Pcri-winkles*, *Andromeda japonica*, *A. floribunda*, *A. calyculata*, the *Goat Willow* (*Salix caprea*), the *Purple Plum* (*Prunus Pissardi*), *Forsythia suspensa*, *F. spectabilis*, *Osoberry* (*Nuttalia cerasiformis*), *Cydonias* (in various colours), *Rubus spectabilis*, *Coronilla glauca*, *Ribes sanguinum*, *Heaths* (in great variety), *Arbutus canariensis*, *Laurustinus* (in variety), *Azara microphylla*, the *Cornelian Cherry* (*Cornus Mas*), *Hamamelis Zuccariniana*, *Snowdrops*, *Violets*, *Crocus* (several species and varieties), *Saxifragas* (various), *Narcissus maximus*, *N. minimus*, *N. pallidus præcox*, *N. Grand Monarch*, *N. Tazetta*, the *Tenby Daffodil*, *Grape Hyacinths*, *Snowflakes*, *Arabis*, *Aubrietias*, the *Algerian Iris*, *Polyanthuses*, the *Greek Anemone*, the *Poppy Anemone* (*A. coronaria*), the *White Wood Anemone* (*A. nemorosa*), the *Scarlet Windflower*, *Scilla taurica*, *S. sibirica*, *Hya-*

clearing of Lily of the Valley beds and pricking over the soil among groups of herbaceous Phloxes has been commenced. Pruning of Climbing Roses, Clematis, etc., still receives attention. A large group of *Bambusa palmata*, which had been allowed to run about of its own free will, was beginning to assume enormous proportions. It was decided to cut down one half to the ground level. This was a rather difficult task, as only a very sharp bill-hook would sever these old canes, some of which were found to be 15 feet long. We are leaving the plants in the ground in order that they may break up afresh. If satisfactory, the other half of the group will be treated likewise another season.

There has been a heavy fall of snow, and many things are prostrate, but very little damage has been done. For the carriage and other drives an improvised snow plough was made by fixing two stout boards v-shaped with two lengths of quartering to keep them in position, a pair of handles for holding it down being fixed over the frame. Weights were added to keep it on

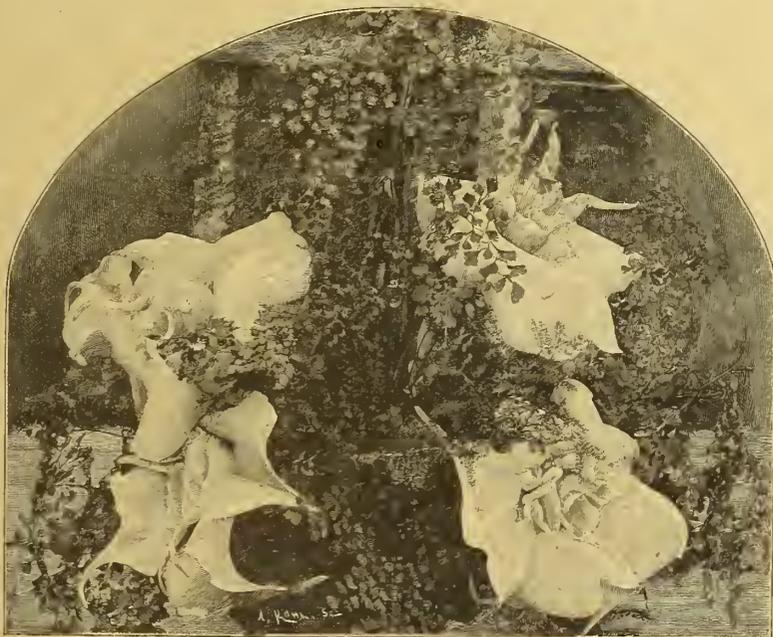

ing through the flowering period syringing of the Vines must cease; in fact, it should no longer be persisted in unless there are very good reasons for doing so, after the berries are visibly swelling. Damping down, except a sprinkling of the floors after closing on fine days, must for the time being be suspended. Black Hamburgs set freely enough without artificial aid, but in the case of Madresfield Court Black Muscat, or any other shy-setting variety, it pays to pass a camel-hair brush or Pampas plume over the bunches about mid-day while they are in flower. Tapping of the rods on fine, bright mornings is not omitted, as this tends to disperse the pollen. Directly setting is complete the border is dressed with a suitable fertiliser, which is washed in with sufficient tepid water to ensure its being well moistened down to the drainage, after which the berries swell rapidly.

Thinning.—As soon as the best set and most shapely bunches can be determined the surplus is taken off, the number in our case being limited to from twelve to fourteen to a rod some 15 feet in length. Though not always possible, the crop is, as far as circumstances permit, distributed on either side of the rods. The tying down of laterals into place precedes the thinning of the berries, which, dull weather excepted, is best done either in the morning or afternoon. To those having many vineries in their charge Grape thinning is a problem that will not be easily solved this season—i.e., under existing conditions—and it will behove all so situated to allow the Vines to carry just what may be termed a sufficient crop only, and to thin as freely as is permissible while the berries are in a small state and the scissors readily manipulated.

Second-house.—Disbudding, best done as soon as the embryo bunches are visible, they will now be reduced to one on each spur. Growth will then visibly quicken and an increase of warmth be required to ensure the bunches developing fully and in a proper manner. The day and night temperatures will, therefore, be raised from 60 degs. to 65 degs. and 55 degs. to 60 degs. respectively. The gradual bringing down of laterals to the wires, the stopping of the same at the second leaf beyond the bunches—the latter being reduced to one, and that the best, when more than one are produced by any lateral—the stopping of sub-laterals to one leaf above the bunches, and rubbing them out or pulling them off altogether are routine matters which each in turn have to be attended to. Between now and the flowering stage being reached the border will receive another watering and be mulched with short litter containing a considerable quantity of horse-droppings.

Late Vines.—Although the houses as yet are being kept cool, care is taken to see that the borders do not want for water. In the case of old and healthy Vines liquid manure, if at disposal, can be given with beneficial results at this juncture if the border is not too dry.

Early Peaches.—The disbudding and the rubbing off of surplus fruits, particularly those which are situated on the underside of the branches, are two of the principal matters now claiming attention. This thinning of fruits must not be carried too far, as a margin must be left to make allowances for a few fruits being cast after the stoning period has been passed, but, at the same time, it is a useless expenditure of energy to allow an inordinate number to remain on the trees until the trying period named has been past and then to dispense with them. Unless absolutely necessary for the filling of any

Datura Knightii.

cinthus azureus, *Chionodoxa Luciliae*, *O. sardensis*, *Lenten Roses* (in various colours), *Puschkinia scilloides*, *Lesser Celandine*, *Aconites*, *Hepaticas*, *Blue-eyed Mary* (*Omphalodes verna*), *Iberis* (in variety), *Wallflowers*.

WORK OF THE WEEK.—A trench 60 yards long has been thrown out, and, the soil being poor, a good deal of it had to be removed and fresh loam brought in to take its place. The trench is required for an additional line of Sweet Peas to be planted out of pots in April. For this purpose the seeds have just been sown this week and placed in gentle heat. A path runs parallel to this trench, and on the opposite side are the autumn-sown varieties. A group of *Thalictrum tuberosum* has been planted in front of a large *Magnolia*, with *Salvia virgata nemorosa* as a background. A few plants of *Sedum atropurpureum* have been added to an existing group in the Grass. *Corydalis cava*, a very early dwarf purple *Fumitory*, which was lifted from the mixed border in autumn, has now been put out. A few rare alpine have been given a place on a raised border, where they enjoy full sunshine. The

the ground, and it was as much as two horses could draw. E. M. Susscr.

SOUTHERN COUNTIES.

Early Vinery.—While the Vines are in flower a day temperature of 75 degs., obtained by artificial means, is necessary to ensure a good set, but it is lowered 5 degs. so soon as the berries are set and swelling. At night the temperature is not allowed to exceed 65 degs. With the changeable weather usually experienced at this time of year ventilation needs very careful attention, otherwise the tender skins of the berries will be apt to become disfigured by rust. The ventilators are therefore slightly opened when the mercury rises to 80 degs., and the volume of air increased afterwards as circumstances demand, but so long as it can be maintained by the heat of the sun the temperature is kept at or near 85 degs. When the latter begins to decline the air is reduced and finally shut off. When the wind is blowing from a cold quarter air should be admitted from the south side only in span-roofed houses. While pass-

vacant spaces the shoots or young growths which will furnish next year's crop should be finally reduced to one on each bearing branch, selecting that, when doing so, as near to the base as possible. The leading growths at the top may, if there is not space to allow them to grow away, after being tied in, be stopped. The other growths alluded to should be carefully tied in as growth develops, and not allowed to grow until they cannot be brought in close to the branch without risk of their either breaking or forming "elbows." Morning and afternoon syringings on a liberal scale are now very necessary, and the water used should always have the chill off it. When warm water cannot conveniently be obtained one or more large pots or buckets filled and stood on the hot-water pipes twice daily will furnish an adequate supply for ordinary purposes. Damping down in accordance with weather conditions also needs careful attention during the day. With a good watering after the fruit was set, root requirements in regard to moisture will at present give rise to no anxiety; at the same time, the border should be tested now and again to guard against falling into a state of false security. Old trees may be assisted with stimulants each time water is applied, but those in a vigorous condition will take no harm if they are withheld until the fruits have stoned. Until stoning has taken place the day and night temperatures should be 65 degs. and 60 degs. respectively.

Second-house.—The weather has not been very propitious for trees in flower, and pollen, in spite of maintaining a warm, dry atmosphere, has not been over-abundant. However, seeing how little of this is required for the fertilisation of each bloom, so long as it is potent, no alarm need be felt as to the outcome. Directly the petals commence to fall and the stigmas to protrude further a gentle dewing with clean tepid water induces the fruits to swell the more quickly, and as they advance in size this may then resolve itself into a vigorous syringing, which will help the fruits to rid themselves of the remains of the flowers. Another watering of the border, which is apt to dry considerably during the flowering period, will also assist in the swelling of the fruit. As disbudding succeeds the pollination of the flowers a gradual reduction of shoots must, therefore, now take place, working from the extremities to the inner part of the trees in doing so, allowing the process to cover a period of ten to fourteen days. At the finish two good shoots should be present at the base—these to be reduced to one unless both are really required—and one at the tip to continue drawing the sap for the nourishment of the fruit.

Late-house.—This must, until the trees actually come into flower, be kept as cool as possible, but when a sharp frost appears imminent the ventilators should be closed and sufficient heat turned on to prevent the temperature falling below 38 degs. to 40 degs. The border should be frequently tested, and water applied liberally when its condition denotes that it is required.

Tomatoes.—Pollination of the flowers must be done as fast as they open, keeping the soil about the roots in the meantime rather on the dry side, as this is an incentive to free setting. As soon as the fruits begin to swell off, a top-dressing of rich compost should be given and stimulative waterings afforded also. Side shoots must be suppressed as fast as they push out on plants grown on the cordon principle, which is really the best method of cultivating Tomatoes under glass, and

the leaders left intact until the limits of the trellis are reached. Plants raised from recently-sown seed are now ready for potting off. Pots 3 inches in diameter are the most suitable for this purpose, and in these the young plants should be placed as low down as possible, so that nearly the whole length of the stems is buried in the compost. They will then be returned to where they were raised until they become well rooted, after which cooler quarters will be accorded them. In due course a fair proportion of the plants will be shifted into 6-inch pots. As these will be required for planting outdoors it is a gain in point of time to have them of good size and well established in advance.

A. W.

MIDLAND COUNTIES.

Melons.—To induce the plants to fruit early the leading growths are stopped when they reach about 18 inches up the trellis. Thin the laterals by the early stopping of superfluous ones beyond their first leaf, in order to prevent the crowding of foliage. Carefully secure the leading shoots, and fix laterals to the trellis, tying them loosely. Stop each lateral at one leaf beyond its first female blossom, which fertilise, and either stop sublaterals or rub them out as may be necessary. During the flowering period it is necessary to preserve a comparatively dry and buoyant atmosphere, and when three or four fruits upon each plant are properly set and swelling remove all subsequent flowers as they appear. At this stage afford a light top-dressing of previously warmed soil, which will be readily filled with roots. Give an occasional watering with liquid-manure. Air early and freely when the weather is favourable, but guard against low temperatures and an excessive amount of atmospheric moisture.

Muscats in flower should have a night temperature of 68 degs. to 70 degs., and a further rise of 10 degs. to 15 degs. on bright days. Keep the points of the bunches near the light, as Muscats do not set well under dense foliage. Fertilise the flowers daily with a large camel-hair brush, using Black Hamburgh or Alicante pollen if obtainable. Examine the border as soon as the Grapes are set, and if found to be dry give a thorough watering. Pay attention to tying down the shoots and stopping the laterals. Later Vines claim attention in the matter of disbudding. Remove the weakest shoots first, as soon as it can be seen which promise to make the best bunches. Select well-shaped bunches in preference to large-shouldered or loose ones. Keep a moderately moist atmosphere by syringing the walls and damping the paths. Give a night temperature of 58 degs. to 60 degs., closing early with sun heat, as this helps to draw out the bunches. The latest house, containing Lady Downe's, has now to be closed for starting.

Raspberries.—Such of the canes as were left at their full length when fastened to the supports should now be shortened to a point 6 inches higher than the stake or wire to which they are secured. Raspberry canes recently planted should be cut down to within 6 inches of the ground to cause strong canes to be thrown up this year for fruiting next year, as, if left at their full length in the year of planting, a few small fruits are borne and then the plants die, there not being enough vigour in them to perfect fruits and produce young canes at the same time. The young shoots that spring from the cut-down canes should be reduced to two when 3 inches in height.

Peaches and Apricots.—So far as one is able to judge, no damage has been done to the blooms of Peaches and Apricots by the frost at the close of February, and if precautions are taken to thoroughly protect the flowers now there is every prospect of good crops of fruit. The only covering used in these gardens is fish-netting in three or four thicknesses, placed in position after the blossoms commence to open. This is kept in position with poles standing out about 3 feet from the base of the wall and let into the border a few inches, being fixed to the coping above. On this the netting is suspended.

Roses.—Most Roses are already in growth, and pruning must be commenced. To prune Roses successfully the operator should be conversant with the habit and growth of the various sorts, as it is advisable that each variety be cut back in accordance with its vigour. Where plants are required to make a good display the pruning should not be too severe. Weakly growths should be removed entirely, as well as all decayed wood, and the remaining shoots cut back to various heights from 6 inches to 1 foot, bearing in mind the constitution of the variety. It is a mistake when pruning Roses to cut all shoots back to one level. China or Monthly Roses as they are sometimes called should be well thinned out, and as the flowering shoots spring from the collar of the plant, too weak ones should be cut down to that part, leaving the other shoots shorter or longer according to strength. The more tender Tea varieties should be left till last. Suckers coming up from the stock that Roses are worked on should always be pulled or dug up, not cut off, when young, but suckers from own-root Roses should be retained, as these develop into strong flowering shoots.

Seed sowing through this month and next demands attention. The embellishment of the flower garden depends very largely on the successful rearing of many hardy, half-hardy, and tender annuals. Many of the hardy annuals (seeds of which can be purchased at a trifling cost) make the garden gay at a comparatively small amount of labour, and are infinitely better than beds of Pelargoniums. All hardy annuals may be sown with safety now, while the majority of annuals succeed, and, indeed, are benefited by being transplanted from the seed beds to their flowering quarters. A few, such as Larkspur, Lavatera, Lupins, Mignonette, Poppy, and Virginian Stock, are best sown where they are to flower, because, being tap-rooted, they do not bear transplanting well. In every case sow seeds thinly, whether in the open garden or in frames, boxes, pots, or pans, as many thousands of seedlings are practically ruined by becoming crowded in their early stages. Seeds of Asters, Stocks, Phlox Drummondii, Nemesis, Salpiglossis, Sweet Sultan, Scabious, etc., should be sown in pots, pans, or boxes, and placed near the glass in cool frames.

Lettuces.—All varieties of Lettuces will succeed if sown on a well-prepared and sheltered border as soon as the soil is in a suitable condition. To obtain an unbroken supply additional sowings should be made every fortnight during the spring and early summer. One of the most useful varieties for early sowing is Commodore Nut or Tom Thumb. Sow the seeds in rows 9 inches apart, and cover $\frac{1}{2}$ inch deep with fine soil. Plants that have been raised under glass should be, when thoroughly hardened, planted a foot apart each way on a sheltered border, taking care to secure a good ball of soil with each plant. If this system be fol-

lowed the plants will be fully as early and generally more satisfactory than autumn-grown produce.

Parsley.—A good sowing of Parsley should now be made even if there is a prospect of the old plants lasting out well, as April or May sowings will sometimes succumb when June happens to be dry, while March sowings grow well. For present sowing a somewhat shady spot is best, and the soil should have been deeply dug and well manured. Sow in shallow drills, and dust with wood ashes before covering in the seed. F. W. GALLOP.

SCOTLAND.

Begonia Weltoniensis.—Cuttings of this useful and showy Begonia having become available, a good number was put in during the week. Of comparatively rapid growth, *Begonia Weltoniensis* can be grown to an effective size in a few months, and such young plants always give better results than older, cut-back pieces do. Apart from its value for the greenhouse, this Begonia is well adapted for summer use in the flower garden, and as it is very easily propagated from cuttings any required quantity can be worked up before planting-out time arrives.

Double Begonias.—These are always appreciated, and a small batch for special purposes now growing freely was potted from the boxes, in which the tubers were started on Cocoa-fibre, into 5-inch pots. At the same time a further, but much larger, batch was boxed in a similar way for general purposes. After an interval a final batch of 100 tubers will be allowed to start in quite a moderate heat for late autumn work. Most of these Begonias are of decided colours, with a few whites and yellows as foils to the brighter tints. It always appears to me that, of all plants, white-flowered Begonias, especially double whites, are singularly ineffective if used separately or in mass.

Begonias for the flower garden.—A beginning was made with the forwarding of the single Begonias required for planting out. These, like the double varieties above referred to, are laid out upon Cocoa-fibre until some growth is made. In their case, however, a bed is made on a narrow border in a moderately warm greenhouse, upon which the tubers are laid, practically touching each other. Growth is not unduly hastened, and by the time the plants are ready for removal the weather is sufficiently genial to permit of their being replanted in beds in cold-frames until the end of May.

Gloxinias.—A further batch of Gloxinias, already showing signs of growth, was potted into 7-inch and 8-inch pots during the week. These, at first, are given a brisk heat, but when growth is well on the move they will be given cooler treatment. These tubers are now in use for their second season, after which they will be discarded. Peat is sometimes recommended for Gloxinias, and while this may be so, excellent results can be had by using well-decayed loam and leaf-mould in equal quantities, with, of course, sufficient coarse sand. One of the best batches I ever grew was potted in leaf-mould and sand alone. The plants made luxuriant foliage and flowered exceedingly well, but they required much more attention in respect of watering—that is, watering at close intervals—than those potted in the usual compost.

Cesneras were also potted up. Three corms are allowed to a 5-inch pot. These can either be grown on, or, should occasion require, the pots can be broken up, each plant receiving a 5-inch pot. Two good batches at an interval of two months

will maintain a display over a long period. The general details of cultivation are similar to those given to Gloxinias, and *Cesneras* can be hastened or retarded in respect of blooming according to the temperature given.

Sowing, pricking-off, and propagating are matters of daily routine at the present time. A large quantity of various *Antirrhinum* seeds was, among other things, put in. These plants are deservedly becoming more popular every year, and are certainly preferable to *Pelargoniums* for flower-beds. Pricking-off is done as soon as the seedlings can be safely handled. Congested seed-pans mean spindly and weakly plants, and if left too long in such a state damping-off is almost certain to follow. As fast as cuttings in the propagating-case are rooted they are removed and potted off, while their places are promptly filled with further needful cuttings.

Cannas.—These cannot, for some reason, be classed as a success out of doors in these gardens, but they have a certain amount of value as greenhouse plants, and during the week the roots have been potted up. In their early stages *Cannas* prefer the heat of the stove, but afterwards a cool greenhouse temperature suits them. They are very thirsty plants, and during the growing season they require copious supplies of moisture.

Flower-beds.—In the course of the week about a score of flower-beds upon Grass were dug up. The near neighbourhood of a number of trees results in the encroachment of the soil by roots, and every year it is necessary to clear the intruders out as much as possible. This is done by digging the beds very deeply and removing the roots. As the work goes on a good dressing of manure is worked in, which maintains these beds in good order through the season.

Wall-fruit.—A look round shows that buds are now becoming prominent on Peaches and Nectarines with a southerly exposure. A continuance of the mild weather will have the effect of expanding these in a short time, and the necessary protecting materials have been got ready. These are coverings which can be affixed to, or removed from, the walls quickly. This method appears to be preferable to that generally adopted—the fixing of three-ply or four-ply netting to the walls in front of the trees, and which is left until danger from frost is over. Very often there is a spell of mild and sunny weather, when the coverings are superfluous; and further, when these can be removed, bees and other insects more easily get access to the blossoms, and there is, consequently, more likelihood of a satisfactory set, although hand fertilisation is by no means neglected, more especially among the earliest trees to come into bloom.

Onion-beds.—Taking advantage of a spell of very suitable weather the Onion quarters have been got ready. The ground is given a thorough dressing of soot, after which it is lightly forked up. Following this, as soon as the forked-up surface is almost dry it is raked and re-raked until it is quite level, and a good tilth obtained. A beginning will be made among the Onions by the transplanting of the autumn-sown varieties, after which seed-sowing will follow. The portion reserved for plants raised in heat is, meantime, not interfered with, being left in a rough state until the young plants may safely go out.

Cauliflower plants from sowings made early in the year make good progress. Owing to losses from damp and from other causes sowing in autumn and wintering the seedlings in cold-frames have been discontinued. If these were not damaged by

damp the comparative mildness of the average winters in this district resulted in plants being too large and weak to be of much service. After all, plants of early varieties sown in heat and well looked after will give heads almost—if not quite—as soon as those from autumn sowing, and frame space is saved.

W. MCGUFFOG.

Balmoe Gardens, Kirkcudbright.

ROYAL HORTICULTURAL SOCIETY.

MARCH 7TH, 1916.

THE fortnightly meeting held on this date was hardly up to the March standard of fulness, several of the larger exhibitors being unable to attend owing to the snow. At the same time, the exhibition was not lacking interest, all departments save those of fruit and vegetables being fairly represented. The more important features were the Tulips from Southgate, the bulbs in bowls and fibre from Messrs. Bath than which nothing finer could be desired, and the delightful lot of *Shortias* from Mr. Perry.—Roses, too, from Oxford and from Twyford attracted largely, as did the *Eucalypti* and *Cytisus* sprays arranged by Messrs. Felton. An obviously beautiful hardy plant novelty (*Isopyrum grandiflorum*) from China was seen for the first time.

HARDY PLANTS AND ALPINES.

These were numerous and in unusually good condition. One of the most fascinating was that entirely of *Shortias* from

Mr. Amos Perry, Enfield, the well-flowered examples as good as could be wished. Only *S. uniflora* and its forms were shown, some of them quite rich in colour. For example, the well-known *S. u. grandiflora* was largely represented. In addition, there were *S. u. Amos Perry*, *S. u. rosea*, and *S. u. superba* (the last a lovely bit of colour). Some hundred or so of well-flowered examples were on view.

Messrs. Barr and Sons, Covent Garden, W.C., had choice Saxifrages, the varieties of *oppositifolia* and *Burseriana* being well flowered. *Iris tingitana* was in this lot, also pretty colonies of *Chionodoxa* and *Narcissus minimus*. Forced Daffodils were very good, Sparkler, Alice Knight (white trumpet), Yorick (yellow trumpet), King Alfred, and Sunrise being some in a large lot, though many seedlings were of merit.

Messrs. Piper and Sons, Bayswater and Barnes, had many good alpine, the rarely seen golden-yellow Saxifraga *Ferdinand-Coburgi* being well in flower. *S. Rocheana* was also good, also *Shortia uniflora grandiflora*.

Mr. G. Reuthe, Keston, Kent, again showed an interesting assortment of alpine and shrubs. Of the latter, *Rhododendron racemosum*, the Portuguese Heath (*Erica lusitanica*), and *Berberis nepalensis* were remarked, while among the former a group of the rich golden-yellow Saxifraga *Haagi* was one of the more conspicuous. The sbapely yellow flowers of *S. Borisi* show that this is but little inferior to *S. Faldonside*, the buff and red *S. Stuarti* showing well. *Ophrys aranifera* and *O. speculum* were among hardy Orchises.

In an interesting lot from Messrs. William Cutbush and Sons, Highgate, N., *Soldanella alpina* was particularly good, also double blue Hepatica, *Tulipa Kaufmanniana*, and Saxifraga (*Megasea*) *Stracheyi*. *Rhododendron racemosum*, *Daphne alpina*, and *Erica carnea*, among shrubby things, were all of merit.

Messrs. J. Cheal and Sons, Crawley,

Sussex, had an exceptionally good lot of *Primula denticulata*, a group of the white-flowered variety *P. d. alba* being very attractive. The strength of these plants is ever best displayed by generous grouping. The rich velvet-crimson *Primrose* Miss Massey was also remarked.

Messrs. Whitelegg and Page, Chislehurst, showed effectively such alpinas as *Primula frondosa*, *Morisia hypogaea*, and many *Saxifragas*, of which *S. Elizabethae* was particularly well done. Some new *Aubrietias* were here too, and of these we remarked *A. Violet Queen* and *A. The Queen* (a novelty with exceptionally large flowers of reddish-lilac). It is of *Arabis*-like vigour of growth.

Messrs. John Waterer, Sons, and Crisp, Bagshot and Twyford, arranged many pretty colonies of alpinas on rockwork, such things as *Saxifraga oppositifolia*, *S. o. alba*, *S. apiculata alba*, and *S. scardica obtusa* (white-flowered) being very good. *S. Faldonside* and *S. Cherry-trees* (probably the two best yellows) were of much merit. *Chionodoxa gigantea*, *Narcissus moschatus*, and *N. cyclamineus* were excellent.

Mr. Maurice Prichard, Christchurch, contributed a variety of well-grown alpinas in pots, a score or so of each kind making quite a representative display. We have never seen finer flowers of *Saxifraga Faldonside*, the nearly shilling-large blossoms being of quite a superior type to those usually seen. *S. Cherrytrees* and *S. marginata* (white) were others of this important genus. *Aubrietia Lloyd Edwards* is of richest purple. *Hepaticas* and *Forsythia intermedia spectabilis* (quite the best of its class) were in great beauty.

Miss C. M. Dixon, Edenbridge, Kent, had a group of *Primroses*, *Auriculas*, *Polyanthuses*, and *Myosotis alpestris* *Royal Blue*.

FORCED BULBS.

The most instructive exhibit under this head was that of bulbs grown in bowls and fibre and staged by

Messrs. R. H. Bath, Limited, Wisbech. No pot-and-soil cultivated examples were ever presented in greater perfection. The bulbs, too, were of many classes, *Tulips*, *Hyacinths*, *Fritillaria Meleagris*, and *Daffodils*, representative of half-a-dozen sections, demonstrating the value of the system. The small-growing *Daffodil W. P. Milner* is ideal for the purpose, *Sulphur Phoenix* and *Lucifer* have rarely been better. The mauve-coloured *Darwin Tulip William Copeland* was superb.

Messrs. R. and G. Cuthbert, Southgate, N., again filled a double table with *Tulips*, arranging a totally different set of varieties from that staged at a previous meeting. The best on the present occasion were *Thomas Moore* (orange), *Vermillion Brilliant*, *Coleur Cardinal*, *Mon tresor* (richest golden), *La Rève*, *White Swan*, and *Golden Lion of Hillegom*.

ROSES.

These from two sources were particularly good. Those from

Mr. Elisha J. Hicks, Hurst, near Twyford, were pot-grown examples, demonstrating excellent cultivation, a dozen or so plants of each sort being staged. Mrs. George Norwood (pink, and one of the sweetest *Roses* yet raised) was very fine, the single crimson *Princess Mary* (a remarkable piece of colour) being quite a feature. Mme. Edouard Herriot was also superbly shown.

Mr. George Prince, Oxford, had a greater variety, chiefly in the cut state. *George Dickson* (deep rich red of fine shape) was excellent. *Fortune's Yellow*, *Climbing Niphotos*, Mme. Edouard Her-

riot, *White Killarney*, and Mme. *Melanie Soupert* were a few of those shown. Sprays of the yellow *Banksian Rose* were also included.

CARNATIONS.

Messrs. William Cutbush and Sons, Highgate, N., arranged excellent stands of *Lady Ingestre* (one of the best of the pink set), *Marmion* (scarlet and white), Mrs. C. F. Raphael, *Carola* (crimson), and R. F. Felton.

Messrs. Stuart Low and Co., Enfield, included in an exhibit of these flowers *Pink Perfection*, Mrs. Mackay Edgar, Champion (scarlet), and others. In that from

Messrs. Allwood Brothers, Haywards Heath, the stands of *Rosette* (of rich cerise tone), *Mary Allwood*, *Princess Dagmar* (rich crimson), *Fairmount* (heliotrope), and *Marmion* were the more handsome.

GREENHOUSE PLANTS.

The group of *Cyclamen latifolium* in variety from

Messrs. James Carter and Co., Raynes Park, S.W., claims attention here, and rarely have these beautiful subjects been more finely staged. Arranged in colour batches of many plants each, the effect was excellent. Of pure whites there were *Mont Blanc*, *Charming Bride*, and *White Swan*, all distinct and of high merit. Brilliant, while good by way of contrast with these, was most effective. *Queen Mary* is of rich salmon. Mrs. L. M. Graves, with a much greater leaning to scarlet, is very telling, though perhaps the silver-leaved *St. George*, with salmon-scarlet flowers, is one of the most effective.

Messrs. H. Cannell and Sons, Eynsford, Kent, showed *Cinerarias*, *Pelargoniums*, and *Cyclamens* in variety. Large-flowered and stellata varieties represented good strains of *Cinerarias*, the brilliant winter-flowering *Pelargoniums*, *Firefly* and *Maxime Kovalesky* (orange-scarlet) being two of the more conspicuous of these.

Messrs. R. F. Felton and Sons, Hanover Square, W., again had a remarkable exhibit of *Eucalyptus resiniferus*, one of the most ornamental and decorative of these plants; also very fine stands of the graceful *Cytisus monospermus*, whose white flowers are in striking contrast with the crimson-coloured calyces. Vases of *Roses Lady Hillingdon* and *Richmond* were very good.

ORCHIDS.

Messrs. Charlesworth and Co., Haywards Heath, had many examples of *Odontoglossum crispum xanthotes* and *Odontiodas*. *Odontoglossum The Czar* (first-class certificate) is rich crimson with occasional lines of white.

Messrs. Sander and Son, St. Albans, had several well-flowered examples of *Dendrobium Wardianum giganteum*; also two pure white *Cattleyas*, C. *Majali Sander* and C. *Mülleri*, together with a variety of *Cymbidiums*, *Coleogyne flaccida*, and *Odontoglossums*.

Messrs. Armstrong and Brown, Tunbridge Wells, had some of their choice *Odontoglossums*.

Messrs. J. and A. McBean, Cooksbridge, showed *Cymbidiums* and *Odontiodas* both in some variety. *Cymbidium Alexanderi Excelsior* (Award of Merit) is of richer rose colour than the original.

Messrs. J. Cypher and Sons, Cheltenham, contributed a variety of *Cymbidiums*, *Odontoglossums*, *Cypripediums*, *Lycastes*, and well-flowered *Sophrontis grandiflora*.

A complete list of the certificated plants and medals awarded will be found in our advertisement columns.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Tulips failing (H. S.).—We imagine your culture is at fault. Very probably you placed them in the stove, which was far too hot for them before sufficient roots had been formed. They ought to have been plunged in the open air in ashes or Cocoanut-fibre, so as to encourage the formation of plenty of roots before the top growth started.

Maiden-hair Fern (Pteris).—You made a mistake in repotting the Fern in December; the beginning of March would have been a better time. When the Maiden-hair Fern is kept altogether in a room it does better in those from which frost is only excluded than in warmer ones. The warmth of your room causes the young fronds to grow; but as soon as they get a little above the soil, the dry, heated air to which they are exposed causes them to die away. Try placing your plant in a cooler room, where it does not get the full force of the sun in the middle of the day.

Deutzia gracilis after blooming (T.).—*Deutzias* that have been forced or flowered in the greenhouse should be gradually hardened off, so that when all danger of frost is past they may be stood out-of-doors. At that time any old and exhausted wood should be cut out in order to allow room for the development of young and vigorous shoots, while, if necessary, the plants may be repotted. The great point is to have the wood well ripened by standing the plants in a sunny position during the summer, taking care that during growth they never suffer from want of water. *Deutzias* will stand for years in the same pots and flower well each season, provided they are occasionally watered with liquid-manure during the growing period.

Zonal Pelargoniums (E. J. Aggett).—Good varieties for your purpose would be *Paul Crampel* or any of its progeny. The class is notable for large trusses of flower, and the growth of the plants is comparatively quick as well as naturally bushy. You should obtain plants in or from small pots, and at once repot into the 5-inch size. They should have a shift later into 8-inch pots, in which they may flower. Loam with a sprinkling of bone-meal is a good compost. In this the growth does not go unduly to leaf. For the time being a shelf in a greenhouse from which frost is kept out will do well for the plants, putting them in a cold frame in May. Take away all flower-buds as they appear up to six weeks of the date of show. When blossoms are developing feed with guano-water or sulphate of ammonia.

Carnations out-of-doors (Dianthus).—If the soil has not been thoroughly dug, lose no time in getting this done at once, incorporating with it some thoroughly-decayed manure if it needs enriching, or, better still, a good dressing of soot, wood-ashes, or any burnt refuse of that description. At planting, which do as early in March as possible, be sure and tread the plants in firmly, as *Carnations* love a firm root-run—in fact, they will not flourish in loose soil. After this the only attention needed is to keep them clean, and when the flower-spikes are pushing up, if fine flowers are desired, it will pay to top-dress them with a little well-rotted manure which may be watered in if the weather is dry. If it is desired to increase them, layers should be put down in July as soon as the shoots are fit for layering.

VEGETABLES.

Celery failing (A. M. M.).—The trouble is due to various causes. Sometimes seed may be saved from a stock that has prematurely sent up flower-stems. Sometimes it arises from sowing too early (the most common cause), sometimes because the plants have inferior culture when young, getting half-starved because overcrowded in the seed-pans or boxes. When the seed is good, plants raised in March or April, the seedlings when strong enough dibbled out under handlights or into other boxes or pans quite thinly, and later culture good, bolting seldom follows.

SHORT REPLIES.

Strobilus.—You may plant *Aucubas*, *Berberis*, *Choisya*, *Enonymus*, *Magnolia stellata*, *Olearia Haasti*, *Rhododendrons*, *Skimmias*, all of which would do well in such soil as you have. —*W. Brown*.—Your query was answered in our issue of February 19th, page 104, under "Short Replies."—*A. B.*—The only thing we can suggest is that very probably the plants were very dry at the roots when you applied the liquid-manure, which was too strong. Fumigation while the leaves were damp would also cause it, while sulphur fumes would also bring it about.—*E. S. Sterry*.—From what you say, we fear you have a grafted plant. The graft has perished, and what you are growing is the stock, probably a variety of the common *Privet*.—*Constant Reader*.—The illustration on page 137 and article will explain the meaning of the term "down hearth."—*F. B.*—See reply to "Oak, Prestbury," in our issue of March 4, page 130, re "Acetylene gas refuse."

NOTES OF THE WEEK.

Vitis Thunbergi.—The large *Vitis Thunbergi* was bought at Boskoop, in Holland, about 1872, and the plant came from Siebold's Nursery at Leiden.—A. W., *Knap Hill*.

Saxifraga oppositifolia rubra.—This is at present (March 6th) flowering freely in Mr. Hornel's rock garden at Broughton House, Kirkcudbright. Suited by its environment, *S. o. rubra* makes large and handsome tufts, almost hidden by its numerous and effective flowers.

Andromeda japonica.—Here *Andromeda japonica* grows in almost any soil, well mixing leaf-soil and a little thoroughly rotten cow-manure. We have some of the large *Rhododendrons* blown over and many on one side. The snow did not do so much damage as the wind. I hope we may soon have some fine, dry weather.—ANTHONY WATERER, *Knap Hill Nurseries, Woking*.

Sweet Peas.—I thoroughly sympathise with one of your correspondents who wrote some weeks ago on Sweet Peas, and said that the new sorts are much too numerous, and also improved and cultivated to simple coarseness. I prefer three blooms to four blooms on a stem, and a row of them 6 feet to 10 feet high, but I suppose I am hopelessly old fashioned.—AN OLD FRIEND.

Rhododendron intricatum.—A fairy bush in the wondrous family it belongs to. Surely the growth of some lofty alpine colossus among the mountains over 12,000 feet high. From Sir Frank Crisp. These winter-flowering kinds are so apt to get spoiled by frost or fog, that it might be worth the while of those men who enjoy winter flowers to grow a few of the best in baskets to bloom in the house in safety.—W.

Antholyza crocosmioides.—I am obliged for your reply *re Antholyza* (March 11th, p. 134). From what I have since heard, I conclude that it is a mistake to pull an old free-flowering plant to pieces as long as it goes on blooming. If pieces are replanted all the tubers should be retained. If the two top tubers only are retained it takes several years before the plant flowers freely.—E. CHARLES BUXTON, *Coed Derw, Bettws-y-Coed*.

Cotoneaster montana.—There have been recently a good many references to *Cotoneasters*, but the above has not been mentioned. It came to me many years ago under this name. I have always looked

upon it as a form of *C. frigida*. Its peculiarity is that the birds let it alone. It is now glorious when the sun is shining upon it. My biggest plant is 40 feet wide by 25 feet high; a shining mass of red. These berries, except those the winter's gales shake off, will be on next April.—T. SMITH, *Newry*.

Eschscholtzia caniculata Mikado.—Everyone is familiar with the popular *Eschscholtzia californica*, but few seem to know the variety of *E. caniculata*, known as Mikado. Of a compact habit, the blooms are produced on erect and wiry stems, and as they are very numerous a fine effect is produced, more especially on sunny days. The flowers are of a bright scarlet touched with orange, which is more intense near the centre.—SCOR.

Iris reticulata.—I do not remember to have seen any notice of one quality in this delightful flower which distinguishes it from nearly all others of the genus, namely, the length of time the flowers remain fresh when cut. The fault of so many species of *Iris* is the ephemeral character of their blooms. *I. unguicularis* lasts well in a vase, but *I. reticulata* long outlives it. I cut some flowers of both on February 24th; to-day (March 2nd) the former has withered away, but *I. reticulata* is still quite fresh and brilliant.—HERBERT MAXWELL, *Monreith*.

Plants in bloom at Warley Place, Essex.—I have just been looking round and although snow has not quite disappeared I find the following in full flower—not a few stray blossoms. In a few days there will be many more.

- | | |
|--------------------------------|------------------------|
| Correa alba | S. Boydii alba |
| Coronilla glauca | S. oppositifolia |
| Pyrus japonica | S. coriophylla |
| Jasminum nudiflorum | Androsace carnea |
| Orobus vernus | A. Laggeri |
| Saxifraga (Megasea) Aitchisoni | Iberis Garreixiana |
| S. purpurascens | Pulmonaria |
| S. apiculata | Andromeda japonica |
| S. apiculata alba | Erica carnea |
| S. apiculata Alberti | E. alpina |
| S. aretioides | E. mediterranea |

| S. Elizabethae | E. codonodes |
| S. Rocheliana | Clematis Armandi |
| S. Boydii | C. cirrhosa |

—E. WILMOTT.

Grevillea angustifolia.—Flowering branches of this attractive greenhouse shrub were staged by Messrs. R. F. Felton and Sons at the Royal Horticultural Society's meeting on February 22nd. The curiously-formed flowers are produced in short terminal and axillary racemes, the greater effect due to the brilliant colour of the inch-long protruding styles of reddish-carmine hue. The narrow leaves,

each 6 inches to 8 inches long, have conspicuously jagged margins, dark green above and silvery beneath, in sharp contrast to the red effect of the flower racemes. The whole plant is hard and wiry, notwithstanding which it is most enduring when cut. The examples referred to were imported, and whether the species is in cultivation I am not aware. In any case it is of high decorative value and worth looking after.—E. H. J.

A fine Arum bloom.—I think it may perhaps interest some of your readers to know the measurements of a white *Arum Lily* now in bloom in my greenhouse. It is the largest one I have seen, and no special treatment given it. I cannot remember from whom I got it, but my gardener says I bought it a few years ago, seeing an advertisement saying it "carried the blooms so well above the foliage," and this you will see it does from the height measurement. It is a splendid bloom, so pure a white and so thick and solid. Only this one bloom is out at present, but two more are coming on, so that it promises to be a free bloomer, as it is a comparatively young plant in an 8-inch or 9-inch pot. The height of the flower-stalk is 6 feet 2½ inches, and the longest leaf measures 52½ inches. The breadth of the flower across is 8 inches, and from the point where the flower folds over to the tip of the bloom the length is 9½ inches.—AN OLD FRIEND.

A winter-flowering Rhododendron.—Of recent years a *Rhododendron* has come to me and others in the district which justifies the description. Not being sure of the name I sent it to Mr. Anthony Waterer, *Knap Hill*, who names it *R. venustum*, and says it was one of the seedlings of arboreum grown there many years ago. Mr. Bean, writing from Kew, says:—

"The *Rhododendron* from Haarlem is very like *R. venustum*, as Mr. Waterer says, but I do not think it quite matches. It is one of the early arboreum hybrids of which some got about without names. If you want more of it, and order either *venustum* or *Jacksoni* from Smith, of Darley Dale, you will get something quite as good and scarcely different."

[The weak point in these winter-blooming kinds is the liability of the flowers to injury from frost, but does not this tell us to grow them in baskets or big pots, so as to be able to readily bring them indoors in mid-winter, and so enjoy them at a dull time for flowers?—W.]

Gardens and water-colours.—May a water-colourist protest against "W.'s" strictures in the note on the above in the issue of March 4th, page 119? If he means by the term "an amateur of painting," the names of Turner, Sargent, and a host of others would show that water-colour is not inferior to or distinct from painting. I venture to think that gardeners have done less to foster true ideals of beauty in gardening than the painters, who, while recording the best that has been attempted, have for centuries sought and immortalised those effects of massed colour and verdure, light and shade, now generally admitted to be the first principles of garden planning. I know no better test of the beauty of a walk or border than its "paintableness."—R. NOLAN FERRALL.

[It is curious how Mr. Ferrall has misread my note. I made no comparisons between oil or water-colour paintings, but tried to make some fun out of a badly-planted garden which the owner excused by using some terms of water-colour painting. Painting, good or bad, was not mentioned. In describing a beautiful garden I should be glad to have the aid of a good artist to paint it, but many gardens are so ugly that an artist would run away from them.—W.]

Potash in the garden.—The note on garden sources of potash in your issue of March 4th is interesting. In view of the fact that the only large deposits of potassium in the world are in Stassfurt, Germany, it is essential that every effort should be made to discover and develop other sources of supply if possible within the British Empire. A most interesting pamphlet, "The World's Supply of Potash," was published by the Imperial Institute last year, price one shilling. But it is desirable that all owners of gardens should, so far as possible, recover their own potash from their own waste-material, such as weeds, hedge trimmings, vegetable waste, and especially Nettles, which contain 2.75 per cent. of potash, or nearly four times the amount contained in any other vegetable material except Wormwood. The potash is easily obtained by burning these materials. The ashes being very soluble must be protected from wet and heavy dews, and frequently removed to a dry place and mixed with super-phosphate of lime. It is necessary that the mixture should be applied quickly to the soil, as it does not keep well. In ordinary gardens it ought to be easy to dig a pit, or, still better, two contiguous ones, so that while one is cooling for the extraction of the ashes the other may be burning any available material. The two pits could be covered with curved corrugated iron supported on iron rods, to keep off moisture. Gardeners would welcome further practical suggestions from your readers on this subject.—L. H., *Nuneham Park, Oxford.*

Primula malacoides.—From the time of its appearing a few years ago—the species secured an Award of Merit in November, 1908, when shown by Messrs. Bees—this remarkable Chinese kind was destined to attain great popularity, a popularity which has not waned. So far as I know attempts to hybridise it with others have not been successful, in which respect it is like another popular Chinese kind, *P. obconica*. Like it, too, the more recently-introduced kind would appear to be endowed with some variability, since it has already given rise to two or three distinct forms as well as others of intermediate colour. Of these alba, robusta, and Rose Queen are the more desirable. Much the finest so far, however, is that recently

introduced by Messrs. Carter and Co., Raynes Park, and which, as "King Albert," gained an Award of Merit at the Royal Horticultural meeting on February 22nd last. Its superiority consists in the warmth of its rosy-lilac flowers—a great advance in this respect on anything yet seen—their larger size and more compactly-arranged whorls of blossoms. It is also remarkable for freedom of blossoming, the array of spikes and the colour of the flowers constituting quite a unique feature.—E. H. JENKINS.

GARDEN PLANS.

MOTHER EARTH OR THE DRAWING-BOARD.

THE few observations I made about Scotney a week or two ago have raised an interesting question. A designer of gardens, whom we will call "Wessex," misconstrued my reference to the "drawing-board." I referred solely to the gardens that were made before English writers and others had thrown light on the subject of true garden design. It is not easy to refer to those old books, they are rare, but the gardens are well shown in Mr. Mervyn Macartney's book on "English Houses and Gardens" (Batsford). They show clearly that there was about as much art bestowed on gardens in those days as people give to kitchen or nursery gardens now. They had straight lines in all directions, not merely round the house, but very often covering the whole of the ground visible from it. Anyone can see that design in any artistic sense of the word was totally absent. "Futilities" is the mildest term that could be applied to them. They steal all the life and character out of the garden.

In the note on "Scotney Castle Gardens," in GARDENING ILLUSTRATED of February 19th, you say: "This is the sort of thing that does not come into the calculations of the man who designs on a drawing-board in straight lines and avenues, and all sorts of futilities to hide the landscape."

(1) It would appear from those remarks that you deprecate the use of the drawing-board, or any attempt at the designing of gardens on paper. (2) You also appear to suggest that the mere fact that one makes a plan of a garden inevitably restricts him to the use of "straight lines and avenues, and all sorts of futilities to hide the landscape." (3) And you further appear to suggest that introductions of "straight lines and avenues" are under all circumstances "futilities that hide the landscape."

Assuming one has an intimate knowledge of the plants, trees, shrubs, etc., required, their habits of growth, and has also studied the situation to be dealt with and made a scale drawing thereof, surely it is practicable to prepare a planting scheme on paper in such a way that they who lack the same intimate knowledge can achieve a success that would be impossible without such a plan. As an instance I might mention the planting of a lake-side, whether for distant or near effect, and even the planting of wild gardens, or even in such quarries as the one at Scotney. Surely it is better for one who knows what is best in such cases to give his instructions in the form of plans and drawings rather than leave the planting during his absence to chance in the hands of some under-gardener who may know well *how* and *when* to plant, but who,

for some reason, may not know *where* to obtain the best results.

The result achieved by thus giving graphic illustrations to workmen will be far less liable to necessitate correction in after years than the mere haphazard dumping in anything anywhere, because it will grow there. Nor is it necessary to depart from the "making good use of the accidents of the ground" because one makes a plan of it. Rather it assures that the draughtsman will, in constructing in miniature the preconception of the results aimed at, find many little ways of improving and simplifying the work. Personally, I have often found that a certain treatment that seemed highly desirable on a previous inspection of the ground could be modified and improved when testing the idea on paper. "WESSEX."

The main question is paper or earth? All other issues are subsidiary to this very important one. Plans may be necessary to professional men in cities, but laying out a garden by means of paper plans is certainly not the best way.

MR. ROBERT MARNOCK was the most trusted landscape gardener of his day. He was a gardener by training, and he knew that work well before he took up landscape gardening. He had good men with him, and plans were essential to his work, and no doubt were as well thought out as they could be; but he told me that however carefully thought out the plan, he found it necessary to modify and improve it on the ground whenever he could. In any work I have had the pleasure of doing in my own or in other places I have never made use of a paper plan or sketch of any kind, but have marked all changes on the ground itself. If any instructed designer can put lines on paper surely he can do so on the ground itself? The only time I have ever worked from a plan has been on making roads, when, some of the work being done by contract, we had a surveyor. Afterwards, on going carefully over the lines I found they were not always of the easiest gradation for the advantage of horse or motor. The only fault I find now is in one place where I did not thoroughly examine the ground after the paper drawing was made. In an up-and-down country things may be overlooked by the surveyor which may have a great influence on the work to be done afterwards.

EDOUARD ANDRE was the busiest gardener in Europe for a good many years. He had to plan out gardens in many places which were far away, and could not, like Sir Boyle Roche's bird, be everywhere, so he had to depend much on paper plans. One day, in discussing with him the effect of such plans on gardening, we both agreed that it was generally bad, and he drew for me some little diagrams of what one might expect in visiting gardens in the neighbourhood of Manchester, or London, or Paris, or Berlin. That shows clearly as anything can the evil effect of office plans even in the best hands.

At that time we went together to see one or two places in Touraine that he had laid out. It is a stereotyped way in France to have an area of gravel round each house or chateau; why it should be so is not clear except it is to keep the burglars from taking advantage of cover. In one place we went to there was level ground on one side of the house. The other side fell into a pleasant vale. No attempt, however, was made in the foreground to keep the two scenes quite separate. That had been done many years ago by André as a young man with stereotyped notions. I asked him: "If you had to do this again

would you do it in the same way?" He replied: "Certainly not," and we quite agreed.

DANGERS OF PAPER PLANS.—The conventional plans which are to be found in every office and every big book on gardening are a drawback to good design. Office plans lead to waste of time and much labour on paper, in often bad light. It leads to the mystification of simple people who might otherwise do good work in farm, garden, or woodland, but who have got the idea that pictures can only be made by professional men in towns. When builders deal with an area of ground about

garden differing from its neighbour according to the taste of the different owners, free from office plans.

A friend of mine, a devoted cultivator of plants, and very successful in that way, left his landscape work to a man now dead, but of some repute at the time, whose plans were generally office made, and to a great extent one like the other. The earth puddings and clumps were not graded in any natural way; they should have been gently flowing to the lawns; they were ugly to look at and difficult to mow and plant; and as the soil was a flinty one the result was most unfor-

TREES AND SHRUBS.

RHODODENDRON NOBLEANUM IN SUSSEX.

I NEVER read a better article on Rhododendrons than the one which, signed "D.," appeared in the issue of GARDENING ILLUSTRATED of March 11th, page 136. So it is quite useless for me to attempt to add anything to what he states. But I would like just to mention that this Rhododendron has been a beautiful sight in a wood on a forest ridge in Sussex—so cheery and bright in the most dismal weather. As an undergrowth in woodland, one can scarcely imagine anything more beautiful.

W.

THE ALPINE FOREST HEATH (ERICA CARNEA) AND ITS VARIETIES.

I HAVE grown for some few years the white and rosy varieties of this attractive little Heath, whose first blossoms usually appear at the New Year. A selection of charming varieties was distributed in 1912 by Messrs. Backhouse and Sons, of York. These were collected by Mr. Richard Potter on the Continent. Although it is, as yet, too early to judge of their beauty, when boldly massed some idea of their value is apparent, and I predict a great future for some of these charming, bright, early forms when they become better known. Some of the names are appropriately chosen, others would have been more interesting had it been possible to name them after some hill, valley, or stream near which they were discovered. So far as growth is concerned they possess the same habit as the parent and are quite as hardy. A little in advance of the others as regards flowering, and the deepest in colour, are *E. carnea gracilis* and *E. c. praeox rubra*. It requires a close inspection to discover any real distinction between them, although I find the former a little more compact in growth. The colours given by the raisers are as follows:—

E. GRACILIS, Italian pink, pale at the base, dark brown tips.

E. PRAEOX RUBRA, rich rose-carmine self, tips deepest madder-brown.

E. KING GEORGE, purple suffused carmine, dark brown tips, a very free-flowering variety.

E. QUEEN OF SPAIN, pale madder-pink, madder-brown tips. My plants of this form have not done so well as the others.

E. PINK PEARL, blush pink, slightly paler at the base. This, of a lovely soft colour, is one of the most distinct.

E. WINTER BEAUTY, pale Italian pink, suffused delicate grey, burnt sienna tips.

E. MRS. S. DONCASTER, rosy-carmine, burnt sienna tips, a very beautiful and promising variety with rather larger flowers than usual.

E. C. J. BACKHOUSE.—The flowers of this variety are, in colour, exactly the same as those of *E. mediterranea hybrida*, although the plant is apparently a dwarfier grower.

E. JAMES BACKHOUSE, pale madder-pink, with delicate suffusion of fawn, rich madder-brown tips. This is a distinct and beautiful form.

E. THOMAS KINGSCOTE, Italian pink, paler at the base, tips rich brown.

E. M.

New Index and Binding Cases for completed Volume.—The Index to Volume XXXVII. of GARDENING ILLUSTRATED is now ready (price 3d., post free 3½d.). The Binding Case for the same volume is also available (price 1s. 6d., by post 1s. 9d.). The Index and Binding Case can be obtained from any newsagent, or from the Publisher, 63, Lincoln's Inn Fields, London, W.C. If ordered together, the price of the Index and Binding Case is 2s., post free.

Rhododendron Nobleanum in Sussex wood in February. Planted some fifteen years in partial shade, about 600 feet above sea level.

a house they have often had no experience of trees or vegetation. In such a case it is easy to get some young man in an office to get out a plan for a place to which it is quite unsuited. The results are seen in gardens and parks everywhere.

Most of the park-like country round London and in the Home Counties is spoilt by planting trees in rings and dots. It needs no elaborate drawing to show that this is wrong.

This stereotyped style in gardening is a great evil, and it is only when one gets away from countries where such a thing is practised that one sees how bad it is. In Madeira, for example, one finds every

tunate for the plants and trees. There was no need to pinch the labour, and all such work should have been done under the direction of an experienced ground workman.

The sum of all this is that it is a complete delusion to suppose that plans for picturesque gardens can be made or improved on paper. In the open air and on the ground things far more important come into consideration—e.g., backgrounds and near groups, views near or distant, gradation of the earth, and nature of the soil and vegetation of the place, all of which call for complete knowledge of the subject and the eye of an artist.

W. R.

FRUIT.

APPLE-TREES FOR PICTORIAL EFFECT.

APROPOS of the notes on this subject, too frequently we find that it is impossible in gardens to combine beauty and utility, and in consequence there is a great waste of good space. This is shown very largely in many modern gardens where fruit-trees are relegated to the orchard or the kitchen garden. Happily, this defect is not present in many of our best gardens, in a number of which there are borders of hardy flowers screening vegetables from the paths, and having behind them some of our best Apple and other fruit-trees. In some good gardens I know there are at intervals Apples trained over pergolas of iron or wood, with Snowdrops, Daffodils, and other flowers beneath. So, also, the trees behind the hardy plant borders when in bloom give most delightful additions to the beauties of the hardy flowers in front. There is, indeed, nothing more beautiful than a fruit-tree in full bloom, as it harmonises with the early flowers of the border, and the two combined afford a picture of floral beauty which cannot well be surpassed.

In certain of our old gardens the aid of the fruit-tree in the garden scheme of decoration was perhaps better understood than now. Their makers had not the wealth of spring flowers which are now at our beck and call, and, possibly as much for their beauty as for their utility, they planted Apple-trees largely in the borders. I know many old gardens where these trees must have been a great feature long ago, and which still reveal in some degree the charms of the combination of Apple blossom and the Narcissi, Anemones, Polyanthuses, Primroses, and other flowers of the season. In addition to the charm of the blooms on the fruit-trees, there is, moreover, that of the fruit. In its various stages the fruit is always interesting, and when the Apples begin to ripen there is a subtle harmony between these and the Sunflowers, the Starworts, the Daffodils, and other flowers. It takes nothing from the attractions of the flower garden to have within its bounds fruit-trees whose beauty does not only consist in the blossoms of spring, but also in the ruddy or golden fruits of the autumn time. If we can admit the Japanese double Cherries or the Crabs into the flower garden or the shrubbery, surely we can find room for our good Apples and other fruits. S. A.

RASPBERRIES AND FAILURES.

C. TURNER's note at page 138 commenting on my note at page 94 is scarcely to the point. He does not read my remarks correctly. He says my advice is unnecessary, and refers to ordinary culture, which all growers of experience know is simple enough. C. Turner says he has a moist, strong loam to deal with, while my note concerned a thin, poor, gravelly soil, that, given ordinary culture as C. Turner advises, produced Raspberry canes no thicker than straws. I am taken to task for advocating what he terms annual culture. I never did. I advised new beds to be made more frequently in such land, and I presume the idea of annuals, as he terms it, arose from the fact that I advised a new bed to be made yearly, but I did not say destroy the others. I advised making a new bed on a fresh site, and by this I meant that it was a good plan to do this, as by so doing one always had good material. It is by no means difficult to plant a few rows of Raspberries, accord-

ing to the requirements, and I always did it at one end of the quarter, destroying the oldest, which may have been five years or six years old at the other end, or if this was not feasible, making a fresh plantation wherever I could. I would ask my critic to read a note in the issue of GARDENING ILLUSTRATED, page 109, on autumn Raspberries, by a well-known fruit-grower, who has had many years experience, and probably has grown some of the best fruit ever seen. Mr. Allan advocates planting annually, so that evidently there is not so much wrong after all. In my case Raspberries were required by the hundredweight daily. My endeavour was to get plenty of fruit of the best quality, and to do this I had to study the soil and vary the culture if necessary. In such a soil I would not keep beds ten years, as advised, however well made, as in such the canes after five or six years become very weak. I have, like C. Turner, been fortunate at times in having a good soil. Though in those days Superlative was not in existence we had others of fine quality. I advised 2 feet of heavy loam, but it must be remembered my soil was worthless, and though I should have added the heavy loam was trenched to that depth, no one would dream of digging trenches and putting in two solid feet of loam. I regret I did not make that point more clear. The loam was placed on the quarter and well incorporated with the top soil as the trenching proceeded, the gravel being removed from each trench. Though a laborious task, it was well repaid, as, once the heavy loam is in position, it can be made good use of for many years. Of course, less would have sufficed on better land.

A few words as to the objection to cutting down the canes to obtain late fruit. It is a common practice to do this, and Superlative is one of the best for the purpose. Many years ago I was employed in a large fruit nursery, and I noted that any canes not sold were transplanted and cut down much lower than one does in a private garden. There was always a quantity of late fruit in consequence, and I found this system in later years just filled the void between the summer fruiters and the late autumn varieties. There was a large demand for these fruits, and it was met in an easy way. F. K.

NOTES AND REPLIES.

Hardy fruit. — Recently-planted trees need to be examined occasionally and all ties and stakes secured to prevent damage from winds, which have been unusually severe this season. Advantage should be taken of suitable weather to have all trees that require it mulched. Mulchings for established fruit-trees should be composed of rich manure, but at this season it is better to apply it in two or three dressings, as a heavy dressing makes retentive soils cold and wet. On soils that are very heavy and cold a good dressing of lime and wood-ashes is preferable at this early season to mulchings of manure. The nature of the soil and the condition of the roots should determine the kind of mulch that is used, for it will do more harm than good if rich mulches are applied to trees when the roots are not in a condition to take up the manurial properties. Mulches applied to recently-planted fruit-trees should be for the purpose of retaining the moisture in the soil, and should preferably be of a light nature.

Strawberry beds.—A resumption of the dressing of the soil between the rows with an artificial fertiliser, which was interrupted by the heavy snowfall, has taken place, and will be brought to a conclusion as quickly as possible. The action of the snow and frost on the soil has been such that it now breaks down more readily than was previously the case.

GARDEN FOOD.

NOTES AND REPLIES.

Pear Olivier des Serres.—The illustration on page 107 shows this fine Pear to perfection, its rather flat, Apple-like shape and distinct eye being well seen. It does remarkably well with me, a row of pyramid trees bearing freely every year. One of the last Pears to be gathered, it often hangs firmly long after the foliage has fallen. Although its season is usually given as February and March, the fruits with me are at their best in the latter part of December and early in January. Every season I have great difficulty in ripening a large number of this Pear. About the end of December little brown specks appear on the side of the eye, quickly developing through the core, and ultimately spreading all over the Pear, the decaying part being very bitter. Large lamps are used in the fruit-room for a few hours in the early morning during December, as the room is rather cold at that time. I suspect the low temperature is the cause of the trouble, but it is such a good Pear that I should welcome the opinion of some other grower who has been more successful with it. The golden-brown skin is very tough, but when this is removed Olivier des Serres is a firm-fleshed and delicious late Pear.—E. M.

[The room is evidently too cold. Try rolling a few of the fruits in tissue paper, placing these in a box and standing in a cupboard in a warm room, and you will find that the trouble you complain of will vanish.—Ed.]

Two useful late Apples. — Though opinions differ as to the merits of certain varieties, I am sure those who wish to grow the best quality Apples will not go far wrong if they rely upon such kinds as Lane's Prince Albert and Newton Wonder for use at this season and up till May. It may be said that Newton Wonder in May is past its best, but I have found it of great value at that date, either for cooking or dessert. This is a great gain, especially to those who can give it cool storage and grow it in quantity. Few Apples at this date are, in my opinion, superior to Prince Albert, and few varieties give a better return. The best results I have had were from dwarf trees, as, owing to its spreading growth and heavy bearing, I think this mode of culture suits admirably. Like the Newton Wonder, this is a good dessert Apple at this season, and crops more regularly than others, owing to its late blooming. Prince Albert, when cooked, is of splendid quality.—M. K.

Celery.—Over-cultivation is the ruin of many crops. Celery is prized chiefly for its crispness and flavour, but so long as this perpetual striving after size is permitted, just so long will Celery be unsatisfactory. In private gardens it ought to be borne in mind that quality is the first consideration, and by growing Celery under more natural conditions that can be procured. Compare one of these huge, pithy exhibition heads with one grown under more natural methods. It will be found that the former is largely composed of coarse outside stalks, while the edible portion cannot be compared with that of the latter in point of sweetness and crispness. Further, the keeping qualities of the smaller and firmer produce are superior to those of the larger and coarser stuff. Less manure and less forcing will, without question, result in better and finer Celery, and, in the case of this vegetable especially, size is not everything.—KIRK.

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

AMERICAN PLANTS IN AN ENGLISH WOOD.

AT one time we used, and still often use, the term American for the evergreen shrubs, for which we are, to a large extent, indebted to the flora of America. Often in our own land the garden is set out in the full sun and exposed to all weathers. In the case of small gardens in suburbs there may be no choice, but in country places there is often a chance of finding some spots of value for growing things more naturally, and of this the

away from all distraction. The garden here shown was made by the late Sir Henry Yorke, and no illustration can give any idea of its grace and variety.

W. R.

AMONG THE HARDY FLOWERS.

SAXIFRAGA BURSERIANA.—It is not surprising to find so many people delighted with the varieties of *Saxifraga Burseriana*. They are all very beautiful and their earliness is a source of pleasure. I would suggest that the authorities should not allow so many names of varieties to be recognised. It may be all right for those who are constantly in touch with the new forms, but it is tantalising to spend money on a new Rockfoal of which a glowing

and grit, and a small proportion of old crushed mortar. I have sometimes added a few bits of charcoal, pounded small, with the result that the plants are more vigorous and healthier.

MOSSY SAXIFRAGES BURNING BY SUN.—No garden can be complete without some of the Mossy Saxifrages. These, like the *Burseriana* varieties, are far too numerous. When the plants are small there is little trouble with them, but when a small cushion spreads out into a big one the trouble of burning in the centre appears. An unsightly patch of decay shows itself in the middle, this spreading rapidly. I think exposure to the sun and drought, even in a shady place, are the causes of this decay, and I am now growing my

A garden of American plants in an English wood.

very best example I have yet seen is the one illustrated here.

Taking advantage of an old deposit of leafy and peaty soil near a stream with good trees overhead and for background, here was a chance of growing the evergreens of America to the best advantage. Many of these trees and shrubs, in the south of England at least, do best in shade or partial shade. No design was needed in this case, except planting in natural ways. There was the most complete repose in the surroundings, formalities were forgotten, and the only care was to shut out the rabbit and the hare, and that was done by means of wire-netting concealed in the shrubs. A rustic shelter is a welcome place of repose,

description appears in a catalogue and to find that it is little, if any, better than one which has been in the garden for a year or two, or, maybe, longer. At present I think *grandiflora*, *Gloria*, *speciosa*, and, perhaps, *crenata* might possibly find favour.

DISEASE IN SAXIFRAGA BURSERIANA.—Probably Mr. E. H. Jenkins may have something to say about this disease (if disease it be), which causes the plants to grow bare in the centre and gradually die off unless broken up and the best bits replanted. I think it may be due to want of top-dressing, as I find that my plants last longer if I work in among the foliage in autumn and after they have flowered some good compost made up of fine loam, some old leaf-soil or peat, a little sand

Mosses on the north side of my rock garden, where they are as brilliant in winter and free-flowering in spring, and much longer healthy.

PRIMULA ROSEA.—To read of the new Primulas which are coming to the front is not an unmixed pleasure. Possibly some of our old favourites are being elbowed out to make room for these new species. It would be a pity were this to take place unless the novelties are so much superior to the older ones that the latter appear poor in comparison. I have been fortunate enough to see some of these novelties, but I do not think that *Primula rosea* has yet found a rival. It has just come into bloom with me, and I am again rejoicing in its lovely carmine-pink flowers.

The question is as to where it can be grown best. This is, I think, in a moist place with, at least, some shade. I have seen it charming by the side of a stream or a pond, but I have observed it quite as delightful in a moist, shady border and in a damp corner of a rock garden. I find it is much better for occasional division, and, where it is not divided for a year or two, some soil should be brought well up about its crowns. If left bare below the neck it is poor and liable to rot off.

THE DONDIA.—I see a patch of the little *Dondia* in bud and almost ready to open. It is possibly on the greenish side to be called "yellow," but it is as yellow as some other flowers which we accept as of that colour. It is a nice plant for a shady place.

AN AMATEUR OF HARDY FLOWERS.

WORK OF THE WEEK.

THE weather during the past week has been most unfavourable to outside work; indeed, with the exception of a day or two, this has been completely held up, therefore attention has been given to those things which could be dealt with under cover. A large batch of cuttings of *Felicia abyssinica*, which were inserted—several in a pot—in autumn have struck almost to a plant, and these have been potted off singly into 60-sized pots and placed in a cold frame. *Verbenas* put in about the same time have been treated likewise; also batches of alpine *Veronicas*, *Lithospermum rosmarinifolium*, and *Shamrock Pea*. Hardy *Fuchsias*, struck and grown on in heat, have made nice plants, and are now given cooler quarters near the glass. A number of mixed varieties of *Cannas* which have been in store for the winter have been potted into 5-inch pots and placed in gentle heat. By starting these early, good strong plants are obtained, which commence to bloom almost immediately they are planted out. Some large *Myrtles* and *Bottle Brush* plants used in the flower garden during the summer have had the surface soil removed and replaced with a top-dressing of good sandy loam and leaf-soil. A small collection of *Perpetual-flowering Carnations* for the outdoor garden has been potted into 4-inch pots and placed in a cool-house, where they receive abundance of air. Seeds have been sown in pans and boxes, including those of *Violas*, *Polyanthuses*, *Arbutus Menziesii*, *Columbines*, *Abronia*, *Cotyledon*, *Giant Armeria*, *Ipomaeas*, *Nolana atriplicifolia*, *Nasturtiums* (climbing), *Gilia dianthoides*, etc., all of which have been placed in gentle heat. A quantity of *Violas* sown in cold frames in autumn has been pricked out 3 inches apart into finely-prepared soil in a frame. Those struck from cuttings inserted in autumn are given all the air possible on fine days. *Pea-stakes* have been brought in, pointed, and prepared, all the longest and best being reserved for *Sweet Peas*. It is a good plan to lay the bundles flatwise in a stack and then place heavy weights of some kind on the top. If this is done they will go much further at staking time and look neater. Smaller sprays for supporting the *Peas* in an early state have also been prepared, and a few pegs for the layering of *Carnations* are cut out as this work proceeds.

Flower-sticks have been cut, pointed, and tied in bundles ready for use. Many plants have come to hand, but owing to the impossible state of the soil these have been placed in cold frames. E. M.

Sussex.

NOTES AND REPLIES.

Sowing annuals.—With the advent of April, annuals that are to be sown out of doors in the places they are to occupy through the summer may soon be put in, and if a good and long-sustained blooming season is required they must have a fairly good piece of ground. In the matter of *Mignonette*, for instance, we are sometimes apt to think that any odd corner will do for it. All annuals pay for hard thinning; in fact, if crowded, the flowering season is soon over. If the better-class annuals, as *Asters*, *Zinnias*, *Stocks*, *Phlox Drummondii*, etc., that were sown some time back in gentle warmth are likely to get too thick before they can be planted out, some may be lifted carefully and transferred to boxes. Annuals intended solely for cutting may be sown in rows on some well-prepared border, as thus they can be kept clean so much more easily than when sown broadcast.

Tree Pæonies.—These have come away very rapidly, and it is to be feared that late frosts may yet do damage to the early buds of these handsome shrubs. In the course of the week all the seed-vessels were removed, and any little thinning of spindly or useless wood which was necessary was attended to. Afterwards a top-dressing of well-rotted manure was given, this afterwards being covered by a little fine soil. All of these *Pæonies* are of great age and of considerable size, and annually make a fine, if somewhat brief, display with but little attention.

Crown Anemones.—Both the double and the single flowered deserve to be more extensively grown. Seeds may be sown in boxes filled with good loam under glass now, the seedlings being planted in prepared borders outside in due course. It is a good plan to mix the seeds with clean, dry sand and then gently rub both in the hands to facilitate the sowing. In the meantime, the outside beds should be deeply dug and well enriched with rotted manure. A position slightly shaded from bright sunshine should be selected. In May and June seeds may be sown outside, the resultant plants flowering freely the following year. I have made it a practice to sow seeds in drills between bush fruits, the latter affording the young plants a welcome shade.—BOURNE VALE.

Anemone stellata.—Last spring over 1,000 corms of the *Star Windflower* were planted in various positions, and now (March 1st) it is pleasing to find that these have, in the majority of cases, survived the winter, and look like giving a good account of themselves. I am rather doubtful as to the hardiness of *A. stellata* in Scotland—not, perhaps, on account of the frost, but from the dangers which may attend the corms from damp during winter until they become acclimatised. At the same time it is only fair to say that a considerable number of corms planted about half-a-dozen years ago have done well, although there has not been any very severe frost to test their hardiness.—W. McG., Balmoe.

Sweet Pea Robert Sydenham.—This is one of the best introduced for a considerable number of years, its colour, shape, and constitution all being in its favour. Wings and standards alike are of a fine orange-salmon shade, and the blooms, of a large size and handsomely waved, are borne, always three, often four, on stout, long stems. Unlike others of a similar colour, the variety under notice is sun-proof. This fact alone ought to make it valuable.—KIRK.

Lobelia Tupa.—This, by no means new, always appears to have been scarce and overlooked. It attains to a height of 4 feet, sometimes more in favourable places. Its rich, bronzy-crimson flowers are in appearance similar to those of *L. cardinalis*, but over 2 inches in length, and closely borne on long spikes. If seeds are sown early in spring, and the seedlings brought on in a warm atmosphere, they will bloom in August.—SCOT.

Crocus Tommasinianus.—This does not do so well with me as *C. Sieberi*. It is pretty, and under more favourable conditions would undoubtedly give a better account of itself. But however grown it is more fragile in constitution than *Sieberi*. *C. Tommasinianus* is quite distinct, with a purplish tint in its pale lilac or pale mauve flowers. Though it began to open after *Sieberi* it has already finished.—C. T.

Crocus Sieberi.—A clump of this has been in flower several weeks, and, though the bulk of the blooms is past, there are yet a few more buds to open. The snow and cold do not appear to have had any harmful effect upon them. The yellow base and stigma are a striking setting to the lilac-blue flowers.—C. TURNER.

INDOOR PLANTS.

POTTING AZALEAS.

REPLY TO "A. E. L."

AZALEAS require ample drainage—this is the first consideration in repotting. Your *Azaleas* want repotting. Before repotting, if you find that the ball of soil is dry, stand the plants in a pail of water, so that the soil is thoroughly soaked. Take clean pots, also clean potsherds, place the largest at the bottom, and medium-sized ones next, over this a layer of smaller ones. For *Azaleas* only the best fibrous peat is of any use. Pull this to pieces, but do not sift it, place the roughest soil over the crocks, and then transfer the plant to its fresh pot. Large shifts at one time are not advisable; young plants in 5-inch pots may be placed in 6-inch or 7-inch ones, which will allow of a nice layer of fresh soil being placed all round the ball of earth, but before doing this the old ball of earth should be divested of any inert soil, and the roots carefully loosened when they are very firmly matted. The new soil must be very firmly rammed down with a blunt stick or lath, so that the new soil is made as firm as the old ball of earth. Allow about $\frac{1}{2}$ inch at the top for water, and as soon as potted and set in position for growing give a good soaking of water from a fine-rosed pot to thoroughly saturate the entire mass of soil. The plants should be shaded from bright sunshine, and syringed overhead as soon as the sun declines, and be shut up with a brisk, moist heat. Do not over-water at the roots, but never let the soil get quite dry. Under favourable conditions the plants will make rapid growth, and as soon as the young shoots get firm, flower-buds for the ensuing year will be formed, and as soon as these begin to plump up the plants must be gradually hardened off by admitting plenty of air, and in July they may be placed out-of-doors to ripen their growth. A cool, moist bed of coal-ashes behind a wall to screen the plants from mid-day sun is the best of positions for them, daily attention as to watering being all they will require until the first week in October, when the pots should be washed and the plants set in their winter quarters, which should be cool, light, and thoroughly ventilated.

NOTES AND REPLIES.

Abutilons.—At the present time *Abutilons* seem to be neglected. Nevertheless, they might well receive a measure of support, for not only is the quantity of bloom produced by a well-grown specimen surprising, but the blooms can be had in the winter and spring with a very moderate amount of heat. Plants raised annually are, perhaps, the best; and cuttings strike readily during February. Gradually pot on until the desired size is reached, and throughout the growing period there must be ample supplies of water, and occasionally of liquid-manure. A good holding loam, with, if possible, a small proportion of peat, and a fourth part of leaf-mould, with a sufficiency of coarse sand, suits *Abutilons* well, and there must be ample drainage. The "legginess" sometimes objected to may be avoided by keeping the plants near the glass and by pinching judiciously, while for winter flowering they may be placed outside in June on a bed of ashes and housed in September.—KIRK.

Single-flowered Camellias.—The lumpy character and formal outline of the double-flowered *Camellias* are, no doubt, answerable for their being much less grown than formerly. This cannot be urged against

those with single blossoms. An additional and very pleasing feature is the cluster of yellow stamens. Among the single-flowered kinds we have of true species the typical *Camellia japonica*, with bright red flowers, and *C. cuspidata*, a white-flowered species, for which Messrs. Veitch obtained an Award of Merit a few years ago. *Camellia Sasanqua*, that develops its small pink flowers before Christmas, is very pretty, while its white variety, which is much scarcer, is decidedly pleasing. Messrs. William Paul and Son, Waltham Cross, raised some very fine single-flowered varieties a few years ago. Among the best are *alba simplex* (white), *Apollo* (red), *Jupiter* (large, rosy-red), *Mercury* (rich crimson), *Minerva* (rose), *Snowflake* (white), and *Waltham Glory* (deep blood-red).—K. R. W.

Scented-leaved Pelargoniums.—These are grown, to some extent, for planting out during summer. In the course of the week the young plants—from autumn-struck cuttings—were taken out of the boxes and mossed up in the way which

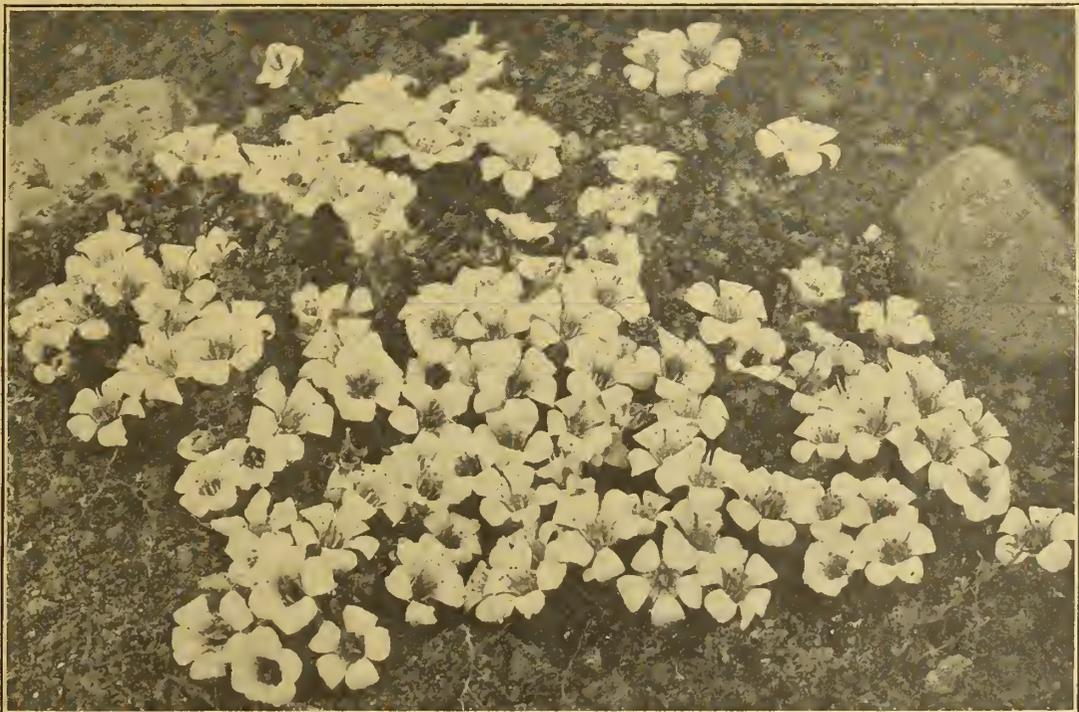

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

SAXIFRAGA OPPOSITIFOLIA VARS.

AMONG the earliest flowering of their race, the opposite-leaved Rockfoils, regarded as a whole, are well known as the most tractable of these plants, affording welcome patches of colour not found in like abundance in any other section of the genus to which they belong. From this point of view, for simple cultural requirements and easiness of increase they occupy a place valuable alike as carpeters of the soil and for a freedom of blossoming quite unequalled. It is during the early months of the year—February and March—that they give of their best, veritable sheets of colour of varying degrees of red, which no description could adequately portray. Welcome in the rock garden in yard wide patches, they are also good in the cool rock wall, and of no little importance to those who indulge in the best of such things for the alpine house. Abundant in

not needed annually in the case of large patches, and in such instances a surface mulching will suffice. Very fine flowering results, however, follow annual increase by division or two-year-old examples raised from cuttings.

VARIETIES.—That shown in the accompanying illustration, *S. o. splendens*, is one of the brightest flowered; *S. o. W. A. Clark* is, perhaps, one of the richest coloured. *S. o. pyrenaica*, *S. o. major*, and *S. o. maxima* are others of the red-flowered set, varying from each other but in minor degree. *S. o. grandiflora* and *S. o. coccinea* are others. Quite among the best is the Italian *S. o. latina*, of rosy-purple hue. These are all characterised by flowers of like form to those shown in the figure. *S. o. pallida* has a distinctive petal character apart from its much paler flowers. *S. o. alba*, while as free and profuse-flowering as any, has much smaller blooms of distinctly starry aspect. In this, too, the only white form with which I am acquainted, good petal quality is

Saxifraga oppositifolia splendens.

was formerly more common than is now the case. Not only does this save pots and space, but the plants, rooting through the Moss, form excellent balls, and when planting-out time arrives they can be transferred to their summer quarters practically without check.—B. G.

Beautiful Heaths in the greenhouse.—In the past, admirers of this beautiful class of plants from the Cape grew them largely and had houses and frames specially for them. That day has gone by, though a few are still popular, such as *hyemalis* and others of the same class, and a few of the spring and summer-flowering varieties, such as *Cavendishi*, *ventricosa*, *propendens*, etc. The war has stopped the autumn trade sales that we found so popular when Heaths and other plants were scattered over the country by the London growers to the manifest advantage of all concerned.—E. H.

Bouvardias.—Stock plants of the varieties grown in pots will now have to be introduced to heat so as to obtain in due course a good supply of cuttings. The plants of *Humboldti grandiflora*, which are to be grown outdoors in a warm border for supplying cut bloom in late summer and autumn, will also be pruned and placed in gentle warmth to start now. When available, a few cuttings will be taken and rooted. Nice bushy specimens for autumn blooming will result. The old plants, as soon as they have started into growth, are partially shaken out and repotted.—A. W.

the Alps and Pyrenees, they are also found on most of the higher mountain ranges, and in Scotland, Yorkshire, and other places, the larger, better-coloured forms coming from the habitats first named. Under

CULTIVATION, while by no means fastidious as to soil, they exhibit an unmistakable liking for strong, loamy soils, not objecting to those of a calcareous nature. In these, indeed, particularly in the case of cool soils, they appear to reach their highest excellence and freedom of flowering. At the same time growing them in pots plunged in sand, hundreds in a batch, in the past it has ever been instructive to note the wealth of flowers on those growths extending beyond the pots into the pure sand of the beds, likewise to observe the freedom of their rooting in the same material. Between strong loam and pure sand there is ample scope for the cultivator, and, given a cool rooting medium—dryness they abhor more or less—failures are few. The best season for transplanting is directly flowering is past. This is

lacking, and in this direction at least there is room for improvement.

E. H. JENKINS.

Saxifraga apiculata alba.—This popular sort is largely cultivated to-day, and, to some extent, its popularity is merited. It is early, free, and, withal, an easy doer. The flowers are made up of small, starry petals which lack whiteness. Moreover, its flower-stalks are weak, and, with age, topple over to a very considerable extent, hence there is room for an improved white *S. apiculata*. I believe, too, there is more than one white-flowered form, as there certainly are two and probably twice that number of varieties of the original, too much alike to be of commercial value, and, doubtless, all in commerce under one name. Curiously, while I have known *S. apiculata* for a quarter of a century or so, and propagated it by hundreds from cuttings, no white sport has ever come my way. To those who get sports I would suggest watchfulness in case the much-needed one of superior merit should occur.—E. H. JENKINS.

ROYAL HORTICULTURAL SOCIETY.

MARCH 14TH AND 15TH, 1916.

The exhibition held on the above dates included the annual show of forced spring bulbs. The outstanding feature was the gold medal collection of Hyacinths from Southgate, N., and only rarely have finer spikes of these been seen. Forced Daffodils, too, were good, the wealth of Crocuses from Edinburgh being also an attraction. Of more than ordinary interest were the Shortias from Enfield. For the rest the collections from various growers of alpine and hardy plants are a never-failing source of interest at these early meetings.

ALPINE AND HARDY PLANTS.

An excellent group of these on rock-work, in conjunction with suitable shrubs, was arranged by Messrs. John Waterer, Sons, and Crisp, Bagshot and Twyford. On this occasion there were several noteworthy groups of bulbs—e.g., Narcissus W. P. Milner, *N. triandrus* (Angel's Tears), *N. cyclamineus*, and the ever-popular white Spanish Daffodil, *N. moschatatus* (Haworth). In addition, *Puschkinia libanotica* was charming. Two lovely blue flowers were *Anchusa myosotidiflora* and *Omphalodes cappadocica*. The rosy-petalled *Fritillaria pluriflora* was beautiful.

Messrs. Dobbie and Co., Edinburgh, sent a fine collection of the best bedding Crocuses in some twenty-five sorts. We regarded Kathleen Parlow the finest white, albeit White Lady, Snow White, and Caroline Chisholm were of high merit also. Maximillian (mauve) stood out from all in this shade. Mammoth Yellow appealed by reason of its rich golden colour and profuse flowering. Albion and Mikado we considered the finer striped sorts. The group of Shortias from

Mr. Amos Perry, Enfield, was the finest exhibit of this unique alpine yet seen. Entirely composed of varieties of *S. uniflora grandiflora*, it embraced several of exquisite shades of rose, *S. u. g. superba* and *S. u. g. rosea* being some of those to which varietal names had been given. Others even deeper in tone were on view.

Mr. Clarence Elliott, Stevenage, had some well-flowered pieces of the charming *Saxifraga Irvingi*, also the large white-flowered *S. Obristi*, *S. Faldonside*, and others. The greater display was, however, afforded by *S. oppositifolia splendens*, of which a hundred or so in full bloom gave quite a feast of colour. A mass of *Soldanella pusilla alba* full of bloom also attracted lovers of choice things.

Messrs. T. S. Ware, Limited, Feltham, had an effective bank of hardy things, such Lenten Roses as *colchicus* and *orientalis* in variety being in considerable force. *Primula frondosa*, *P. denticulata*, and its white variety, a fine lot of *Anemone blanda*, *Iris reticulata*, and *Saxifraga Griesbachi* were very good. The blue-flowered *Synthyris reniformis* was among the more interesting things.

Messrs. Barr and Sons, Covent Garden, W.C., had many pretty groups of bulbous flowers, *Chionodoxa*, *Crocus* species, the fine white bedding *Crocus*, Kathleen Parlow, and *C. purpureus grandiflorus*, *Narcissus minimus*, and others. *Iris unguicularis* was well shown.

Mr. G. Reuthe, Keston, Kent, showed the unique Grecian *Crocus*, *C. aerius*, whose violet-blue, well-formed flowers are a great attraction. *C. Alexanderi* and *C. aureus* were also shown. A remarkable lot of *Saxifragas* was on view, Haagi (golden-yellow), *Obristi* (the finest white of the moment), Pauline, and Borisi, a pair of yellows outside, Boydi and Faldonside, being the best.

Messrs. Bakers', Wolverhampton, staged many showy things, *Primula marginata* in variety, *Ranunculus montanus* (glistening yellow), and the beautiful mauve-coloured *Ramondia serbica* being among them. *Saxifraga* (*Megasea*) *Afghanica* (white) was also noted.

Mr. G. W. Miller, Wisbech, had an extensive exhibit of *Primroses*, *Polyanthuses*, and other spring flowers.

GREENHOUSE PLANTS.

Messrs. M. Gleeson and Co., Watford, had an excellent lot of the fringed or *Papilio* strain of *Cyclamens*, which included many of exceptional size and colouring. The plants were exceptionally well grown and flowered.

Messrs. H. B. May and Sons, Limited, contributed a delightful lot of the fragrant *Boronia megastigma*, also *Cinerarias* and *Cyclamens*, showing a considerable colour range, the former particularly in the crimson, blue, and pink shades. In a central group of *Clematisses* we noted such good things as *Miss Bateman* (white), and *Lady Londesborough* (mauve).

Messrs. R. H. Bath, Limited, Wisbech, again showed bulbous plants grown in bowls of fibre, *Mme. de Graaff* Daffodil, also excellent bicolors and yellow Ajax sorts, *Tulip Hector* (orange and gold), and the mauve-coloured *Darwin Tulip*, *William Copeland*, claiming attention.

Messrs. William Cutbush and Sons, Highgate, N., showed *Azaleas*, *Rhododendrons*, *Wistaria*, *Magnolia*, and other forced shrubs, with hardy flowers at one end. *Tulipa Kaufmanniana* was very good, also *Saxifraga* (*Megasea*) *Stracheyi*.

Messrs. Stuart Low and Co., Enfield, had some good vases of *Carnations*, *Mrs. Mackay Edgar*, *Pink Sensation*, and *Mrs. C. F. Raphael* being some of the best.

Messrs. R. F. Felton and Sons, Hanover Square, W., again displayed great stands of the charming white-flowered *Cytisus monospermus*, one of the most graceful of flowering shrubs. *Ruscus Androgynus* was also remarked for its fine rich green and high decorative properties generally.

SPRING GARDEN.

Messrs. Carter and Co., Raynes Park, contributed a somewhat suggestive piece of gardening, which, enclosed within a planting of Box trees, took the form, for the most part, of naturalising Crocuses on Grass. These were in several shades of colour and not overdone. Beyond the Grass was a narrow border filled with yellow *Crocus*, Grecian Windflower (*Anemone blanda*), Lenten Roses, and other plants; the 6-foot wide borders at right and left, planted with *Euonymus*, were carpeted with well-flowered examples of *Erica carnea*.

ROSES.

Mr. Elisha J. Hicks, Twyford, Berks, showed stands of cut Roses, also pot-grown plants. The former were chiefly *Mrs. Charles Reed* (flesh-pink), very delicate in colour and beautiful in form, and the richly-coloured *Mme. E. Herriot*. The pot-grown examples included *Princess Mary* (single, intense crimson-maroon), *Mrs. John Foster* (reddish-carmine), and the lovely pink, *Mrs. George Norwood*; valuable Roses all, the last three more particularly, by reason of their pronounced fragrance.

Mr. George Prince, Oxford, also had some fine cut blooms, his stand of *Mrs. W. J. Grant*, for size and colour, in the nature of a revelation. *Mme. E. Herriot* was of exceptional colour, showing how well it stands forcing. *George Dickson* (intense maroon-crimson) and *White Killarney* were others of note.

NARCISSI.

Messrs. Barr and Sons, Covent Garden, W.C., staged quite a large collection, many being unnamed seedlings. Of those named, *Sparkler* (rich red cupped incomparabilis) was most attractive. It gained an Award of Merit. *White Queen*, *Sunrise* (very shapely flower), *Ornament* (a brilliantly-cupped Barri), *Sunbeam*, *Mermaid* (a giant Leeds), and *Yorick* (a rich yellow Ajax) were a few of the best.

Messrs. J. R. Pearson and Sons, Lowdham, had a particularly fine thing in *Heroine* (*Englehearti*), whose poeticus white segments and lemon cup fringed with apricot-orange rendered it, most telling. *Vega* (giant Leeds), *Margaret* (white Ajax), *Great Warley*, *Potentate* (handsome yellow Ajax), and *Bernardino* were other excellent sorts.

Messrs. Robert Sydenham, Ltd., Birmingham, had a fine lot of the yellow-trumpet Daffodil *King Alfred*, still unique amid them all. *Princess Ida* (a very early white) was also in evidence, and a fine lot of a pure white *Freesia refracta alba* without yellow blotch. It is both good and distinct.

FORCED BULB SHOW.

The gold-medal collection of Hyacinths arranged by Messrs. R. and G. Cutbush, Southgate, N., was the outstanding feature of the meeting, and finer examples than those staged it would be difficult to find. Red, white, and blue varieties were strongly in evidence, these appearing as side lines to the whole. The central part, made up of circular groups, was somewhat weak owing to the low-placed position of the plants, and, as we thought, a too free use of Ferns in the groundwork. This in large degree obscured the Hyacinth foliage. The high quality of the Hyacinths, however, merited unstinted praise. The best sorts were *City of Haarlem* (yellow), *Jacques*, *Moreno*, *Coral Gem* (pink shades), *La Grandesse*, *Corregio* (white), and *Perle Brilliant*, *Schotel*, and *Grand Maître* (blue), the last named having great massive spikes.

The remaining five classes were all devoted to Hyacinths, and while good quality was general, competition was far from keen. For twenty-four Hyacinths, eighteen distinct varieties, three competitors entered, His Grace the Duke of Portland, *Welbeck Abbey* (gardener, Mr. J. Gibson), taking the lead. The best were *La Grandesse*, *Corregio*, *President Kruger* (white), *Perle Brilliant* and *Schotel* (blue), *Jacques*, *Moreno*, and *Queen of Pinks* (pink shades). Mr. R. G. Morrison, *Wavertree*, who was second, had *Queen Emma* and *White Lady* (white), and *Gounod* (fine blue) among others.

For twelve Hyacinths, distinct, Mr. W. Joyce, *Wavertree*, was the only exhibitor, *Lady Derby* (pink) and *Corregio* (white) being good. For six varieties, distinct, Mr. J. Haslam was first and Mr. T. Compton second.

Six pans of Hyacinths, ten roots in each, brought two competitors, the Duke of Portland being a good first. His set was *La Grandesse* (white), *La Victorine* (red), *King Menelik* (purple), *Schotel* (blue), *City of Haarlem* (yellow), *Moreno* (pink). Second, *Marquis of Ripon*, *Coombe Court*, *Kingston Hill*. These two exhibitors occupied like places in the class for the finest decorative display of Hyacinths, both arranging a score or so of pans, ten roots or more in each, in a bed of Ferns backed by Palms. The quality was less good in this than in the preceding class, and no new variety of outstanding importance was observed.

FRUIT AND VEGETABLES.

Messrs. Sutton and Sons, Reading, staged a useful assortment of vegetables and salads. Of the former, Snow White Broccoli was arranged in pyramids. The curds were very pure and of solid formation. Harbinger Cabbage from a July sowing demonstrated the value of this sort. The Sutton Rhubarb, Market White Seakale, and Golden Ball Lettuce were excellent.

Mr. G. W. Miller, Clarkson Nurseries, Wisbech, had an excellent exhibit of "The Sutton" Rhubarb, remarkable for the richness of its colouring internally as well as externally.

A full list of the certificated plants and medals awarded will be found in our advertisement columns.

Royal Horticultural Society, Meetings and Committees.—The next ordinary fortnightly meeting is fixed for Tuesday, March 28th, when all the committees are asked to meet as usual.

THE WEEK'S WORK.

SOUTHERN COUNTIES.

Border Carnations.—The planting of these having been interrupted by the spell of wintry weather, it has now been brought to a conclusion. The soil was rather wet, but by taking care not to trample it more than was necessary no ill results are likely to follow. As intimated in a previous note, the plants have to be netted to protect them from sparrows.

Lothian Stocks.—The surplus plants raised from seed sown last autumn, and which were potted off, have been put out in groups in a mixed border, where they will in due course afford a quantity of flowers for cutting in addition to brightening the border.

Mignonette.—The first lot of seed of the large or Giant flowered strain will now be sown on a border at the foot of the front wall of ainery facing south. In the course of another fortnight a sowing of the ordinary large-flowered type of Mignonette will be made on a border in the open. The flowers on the earliest batch of plants in pots are now in perfection. By preventing seed-vessels developing and feeding with stimulants in a liquid form, the plants will continue to yield flowers for some time to come. A successional batch of plants which are coming on apace has been staked and tied.

Schizanthus.—The blooms on the earliest raised plants are commencing to open, but until the flowering stage is more advanced they will remain in their present quarters. They will then be used for the decoration of the show or flowering house. Stimulative food is now being afforded, which will be continued until the plants are in full bloom. A later raised lot of plants, which will succeed the preceding, is being kept back as much as possible, and is still occupying the same position on a shelf close up to the glass.

Hydrangea hortensis.—The flower-trusses on the earliest started plants being now visible, the roots are being fed with Clay's fertiliser to ensure the production of fine heads of bloom. Another lot of plants started later is breaking well. These will be allowed to come on more slowly. The latest lot will now be overhauled, partially shaken out, and repotted. Those which give no indication of flowering will be cut back so as to break from the base. Even if they do not produce flowers this season, the new growths will certainly do so next year if the wood becomes well ripened by the autumn.

Azaleas.—More plants of *A. indica* and *A. mollis* have been placed in heat to be forced into bloom in order to keep up a succession. A number of white-flowered varieties of *A. indica* are being held in reserve for blooming at Easter.

Gloxinias.—These having started nicely into growth the tubers have been shaken out and potted in a mixture of one-half fibrous loam, one-quarter peat, one-quarter leaf-mould, and a liberal quantity of coarse silver sand. The pots, 5 inches in diameter, have been thoroughly cleaned. When sufficiently rooted, the largest of the plants will be shifted on into pots two sizes larger. For the present they will be given a suitable position in the stove, where the heat and moisture necessary for the well-being of the other inmates will promote a vigorous growth and at the same time they will receive the needful amount of shade from direct sunlight. Seedlings should now be pricked off into thumb-pots, one plant in a pot, and grown on in a moist heat, keeping the pots near the glass.

Pot Vines.—As soon as the berries have finished stoning the bunches need a final look over, when relief must be afforded by nipping out inner or misplaced berries which are at all likely to impede the swelling of those situated

on the shoulders or towards the points of the bunches. Stopping of sublaterals and the pinching of laterals allowed to extend while stoning was taking place must again have close attention. An outbreak of red-spider has to be guarded against, while spells of wintry weather are likely to be experienced, which necessitate much artificial heat being required to maintain the requisite temperatures. A moist atmosphere is a preventive, but it must not be overdone, as there is a risk of rusting of the berries occurring should the wind be in a cold quarter and the weather sunny when the admittance of cold air is unavoidable. The old-time remedy of sponging with warm soapy water directly any portion of the foliage is noticed to be infested with the insects is still one of the best antidotes when the attack is in the initial stage. To meet the extra demand on the roots which the final swelling of the berries entails feeding must be regularly attended to. To encourage the further production of surface roots, which play such an important part in the finishing of a crop of Grapes, another top-dressing of rich, warm compost must now be afforded. If well watered as soon as applied, which will settle it at once into place, the active roots beneath it will soon extend and take possession of it. For the present, routine matters, such as damping down frequently on fine days, particularly at closing time, and the maintenance of regular day and night temperatures, should be continued as before.

Celeriac.—Seed should now be sown in the same way as for Celery, and raised in mild heat. A box is a suitable receptacle for the purpose, as the seeds can then be sown more thinly, with the result that there is less risk of the plants becoming drawn. Main-crop Celery should be sown now under the same

Gladiolus Colvillei The Bride.

conditions as the preceding. The remainder of the heads of late Celery has been lifted and laid in elsewhere and the ground dug ready for the next crop, which will be Beet-root.

Seed-sowing.—More Lettuces, both of the Cos and Cabbage varieties, Radishes, Spinach, Turnips, and Shorthorn Carrots will now be sown. On a sheltered border, summer and autumn Cauliflowers, Cabbages, Brussels Sprouts, Autumn Broccoli, and Leeks will also be sown in drills 1 foot apart, and secured from bird attacks by nets. Several more rows of Broad Beans, both tall and dwarf, will be sown at the same time. A. W.

MIDLAND COUNTIES.

Calanthes are starting into growth, and must be repotted. Turn the plants carefully out of their pots, and shake away the exhausted soil, cutting off the old roots to about 1 inch, the part left helping to keep the pseudo-bulbs steady in the new soil until the plants are established. The soil should consist of one-half turfy yellow loam, one-fourth dry cow-dung or well-decayed leaf-soil, and one-fourth finely chopped Sphagnum Moss, small crocks, and coarse silver-sand. Half fill the pots with drainage, over which place a thin layer of loamy turf, with the grassy side downwards. When potting, shake the soil down moderately to firm around the base of the pseudo-bulbs—to within $\frac{1}{2}$ inch of the rim of the pot, this leaving sufficient space for a top-dressing of fibrous loam when the plants are in active growth. I prefer to plant the pseudo-bulbs singly, using pots 6 inches in diameter for the strongest and 5-inch for the remainder. The plants are given the lightest

and best position in the Melon-house. Give no water at the roots until the plants have been potted two or three weeks, merely syringing between the pots several times a day, according to the state of the weather. When the new growths have begun to grow, slightly sprinkle the soil with water. If the soil be made too wet the tips of the young roots decay and the health of the plant becomes impaired. The stock of any particular variety may be increased by taking off the old hack bulbs previous to potting and inserting them close together in pots or shallow pans filled with Sphagnum Moss, but affording no water. Place them in a light position, and when the bulbs commence to grow pot them singly, as previously advised.

Perpetual-flowering Carnations.—Plants raised from cuttings inserted early in January are making good progress, and are now ready for shifting on into 4-inch pots. Plants that have been flowering all through the autumn and winter are again developing strong growths, and, given bright weather, will produce many more fine flowers. The plants are regularly fed with suitable stimulants. Carnations generally do best in a dry atmosphere, but occasional syringing is necessary to keep down red-spider. If red-spider is present a little sulphur in the water used for syringing will prove effectual.

Clematis.—Among hardy climbers, no plants equal the Clematis in variety or beauty. They may be planted at any time from September to May, but in most localities March is the most suitable month. They are mostly gross feeders, and should be planted in well-prepared soil enriched with manure, and if naturally devoid of lime some should be added. The Clematis may be used to cover walls, but looks best when creeping over an old tree or shrub, or trained over a pergola or arch. Rough Oak branches may also be used for them, either singly or several together to form a pyramid. Clematis Jackmani varieties are effective in beds and to cover arches. These require pruning back hard this month. Clematis montana looks well if planted so as to creep up among the stems of Wistaria sinensis, and, both flowering in May, they form a pleasing contrast. C. Flammula is a vigorous grower, developing a mass of small, white, fragrant flowers in August. It should be planted where it has plenty of room to ramble. To C. lanuginosa the beauty of the garden hybrids of Clematis is due, producing lovely blooms of a wide range of colour from July to October. These varieties flower from the wood made the previous season, and only require thinning and the tying in of the younger shoots.

Eremuri are now growing strongly. E. himalaicus, E. robustus and its varieties already pushing up flower-spikes, which need protection from frost and snow. Water lodging in the crowns of the plants and becoming frozen destroys the tips of the flower-spikes, otherwise they are perfectly hardy. E. Bungei and E. Olgae being later require no protection whatever.

Viola cuttings wintered in frames are now well rooted and ready for removal to permanent quarters as soon as the weather is favourable. For best results a well-worked rich soil which will retain sufficient moisture and food for their summer requirements is desirable.

Celery.—The earliest sowings of Celery have been pricked off into boxes and are given a genial temperature. Later sowings may be safely pricked off when quite small, either into cold frames or on sheltered borders where they can be protected from cold, drying winds and frosts. The surface should be dressed with a fine, light, sandy compost to give the young seedlings a start.

French Beans.—Little difficulty should be found in keeping up a good supply of these where sufficient glass is at command. Whether grown in pots or planted out, very little fire heat will now be required during the day. I shall shortly be sowing a quantity in small pots for planting out in cold frames. These will give good returns until pickings can be made from the open ground. Canadian Wonder and Ne Plus Ultra are reliable kinds for this purpose.

Potatoes.—By the end of this month, if the ground is dry enough to bear walking upon, the planting of Potatoes should be commenced. If the ground has been thrown up in ridges during the winter, which is the best plan when possible, the easiest way of planting is to place the Potatoes at the proper distances apart in the furrows and then split the ridges with a snade and throw the earth into the furrows. This ensures loose ground around the tubers, without which a heavy crop cannot be expected. If, however, the ground has simply been dug over, trenched, or bastard-trenched, open a shallow trench about 6 inches deep, lay the Potatoes in it, and fill the trench up again. Another plan is to dibble the tubers in to about the same depth, but this should only be practised on fairly light and well-drained soils. If a quantity of wood ashes be scattered over the Potatoes the crop will be increased in quantity and the chances of disease reduced. I believe that Potato disease is often caused by a too free use of artificial manures.

Seakale.—As soon as the weather is favourable, the required number of sets for provid-

ing strong crowns for forcing next year will be planted. The sets that were prepared during winter and laid in sand are now forming several shoots at the top. These will be rubbed off with the exception of two of the strongest. The ground for this crop has been well manured and deeply dug, and when sufficiently dry will be well trodden and raked over. Draw shallow drills, 18 inches apart either way, and dibble the sets into the angles thus formed. Cover the crown of the set with about 1 inch of soil. Generally speaking, one or two shoots take the lead, and by leaving two at planting time it will soon be seen which is the better. The remaining one may be rubbed or cut off. Should rain be unlikely, a good watering should be given immediately after planting. Run the Dutch hoe frequently through the plants to destroy small weeds and aerate the soil. F. W. GALLOP.

SCOTLAND.

Greenhouses.—After bulbs, and forced stuff generally, are over, there is occasionally an interval, more especially when cutting is done to any extent. The space thus provided is welcome, for under glass there is almost always a congestion where young plants are being potted on and when seed pans and boxes of pricked-off stuff require to be accommodated. Daffodils and other spring-flowering plants and shrubs begin to be useful for cutting, and there is not now the same necessity for maintaining a regular supply indoors. At the same time, these structures are yet interesting and bright. Nothing, perhaps, is of more service than *Cineraria stellata* during the spring months. Apart altogether from its value for decoration, its light and elegant sprays are very effective when cut, lasting well when regularly attended to. The plants, more especially those of a compact and not too lanky type, are not without value for vases. A good batch of *Alonsoa incisifolia* now beginning to flower gives a very welcome and distinct touch of colour. This succeeds best in 5-inch pots, for if given too much root-run the plants are apt to grow rather straggly. *Schizanthus Wisetonensis* comes on apace, and will be useful in a short time. Arum Lilies, now blooming freely, require to be assisted with liquid stimulants. Nothing is better for this purpose than weak soot-water, this not only being of value to the roots, but making the foliage of a deep shade of green. The various kinds of Primulas are also effective. Cyclamens may be used advantageously, and Zonal Pelargoniums, of course, are always useful. One of the surprises of the present season has been a very good secondary display from a number of *Salvias*, chiefly *S. splendens* and *S. lactiflora*. These were retained principally for producing cuttings, and as they were not cut very closely back, and given a comfortable heat, the side shoots came away freely and flowered well. With more sun heat, firing is not now so heavy, and it is possible to ventilate much more freely. Watering becomes more insistent with the brighter sun, and a look out has to be kept for outbreaks of aphid among *Cinerarias* and Arum Lilies.

Stove.—All the necessary repotting meantime needed having been attended to, the work for some time will be of a routine character. Many seedlings and young plants are being given a start in the temperature of this house, and close attention to their requirements is imperative. Syringing has again been renewed, this being done early in the morning and again about 3.30 p.m. Temperature at night, 65 degs.; and top ventilation may be given for a couple of hours in the middle of the day when the sun shines.

Salvia patens.—While this fine blue *Salvia* may be readily increased from cuttings taken from tubers started in heat, it is, nevertheless, advisable to sow a few packets of seed occasionally. Seedling plants, I think, throw finer spikes, and if they do not bloom quite so early as those from cuttings, their flowers come in at a very useful time and prolong the display. During the week a quantity of seedlings was pricked off, these being given a comfortable temperature in order to give the young plants a good start before removing them to a cooler place.

Cosmos.—In view of the value of this family, seeds were sown during the week, the white and the pink varieties being used. The old *C. bipinnatus* never was really reliable owing to its late habit of blooming and its rather gross growth; but with the advent of the earlier types the popularity of *Cosmos* has been assured. Sown now in shallow pans, and given ordinary greenhouse heat, the seeds readily germinate, and the plants will be quite ready for transferring to their permanent quarters in May.

Tomatoes.—In the course of the week a large batch of Tomatoes for pots was pricked off. In order to economise time later on the seedlings were put into 8-inch pots, each pot holding four young plants. In these pots the young plants will be permitted to grow for some time, and will then be transferred straight into their fruiting pots. This will save the usual shifting on, and as Tomatoes are very accommodating, given a little care in respect of watering for a time, there appears to be no reason why they should not succeed perfectly well under this method of cultivation.

Peaches in bloom at this time must not be neglected in the matter of fertilisation. Insect life is not yet much in evidence to assist in the dispersal of pollen, and, at any rate, it always pays to assist artificially. The camel-hair brush is favoured by many; but equally good results may be attained by the use of a rabbit's tail, and a given area can be more quickly attended to when the latter is used. One very good gardener under whom I worked used to fertilise Peaches and Nectarines—as well as orchard-house trees—by means of a large fan made with turkey feathers, which he agitated in front of the trees, the breeze thus caused dispersing the pollen effectively. The plan was a good one—the work was done in a comparatively short time, and the set of fruit was always excellent. The fan was used only on bright days when the pollen was thoroughly dry.

Digging.—The weather being highly favourable for outside work, digging has been pushed on as rapidly as possible during the week. Among other pieces to be dealt with a long, narrow border devoted to herbs was taken in hand. The border has been deeply trenched. A crop of Kale or some other of the Brassica family will be taken from this quarter, the herbs, meantime, being transferred to another part. During frosty mornings manure is wheeled to such breaks as are in the course of being cleared. Winter vegetable quarters will shortly need attention, and where it is possible to do so, the manure is wheeled to and stacked on portions bared for the purpose. This permits of the work being carried out without delay when the last of the vegetables are finally cleared.

Rubbish-burning.—A beginning was made in the course of the week with the usual burning up of rubbish. The ashes thus obtained are of much manurial value. Wood ashes are rich in potash, and are, therefore, well adapted for the cultivation of Potatoes and other crops for which this substance is useful. If it is impossible to use the ashes at the time, care must be taken to store them under cover or at least to protect them from wet. If exposed to rain a great percentage of their value is lost.

Slugs, snails, and vermin generally are more active in spring than at other times. Rats and mice, driven by the growing scarcity of food in the fields, are apt to draw in to the environs of the garden. As soon as their presence is noted, they must be promptly dealt with by means of traps, snares, or poison. In the last case the substance used should be in careful hands. Slugs and snails are at times introduced into plant houses during the course of the customary repotting, and, especially in the case of Ferns, they soon make their presence visible. They may easily be taken after nightfall by using a bright light, and whenever their traces are seen regular inspection nightly until they are accounted for ought not to be omitted. W. McGRUOP.

Balmae Gardens, Kirkcudbright.

OBITUARY.

MR. EDWARD HOBDAY.

We regret to announce the death at the age of 83 of Mr. Edward Hobday, for many years gardener at Ramsey Abbey, Huntingdon. On leaving that place he started a nursery at Cambridge, the management of which, in his declining years, he handed over to his sons. One of the old school of gardeners, before the days of colleges to teach the art were thought of, his advice in all branches of gardening was practical and thoroughly reliable. He was for many years—in fact from the first issue of this journal—and even up to the day of his death, one of our most esteemed contributors, and there was no man better able to express clearly his views, and no one whose views on plant culture were more fully the result of long and careful practical study. A keen lover of hardy plants, Mr. Hobday also gave considerable attention to the once favoured hard-wooded greenhouse plants, but perhaps it would be accurate to say that his chief distinction was gained as a vegetable and fruit grower. An all-round man, genial and well informed, Mr. Hobday was one whose death is a loss to the gardening world at large.

Gardens for soldiers.—This camp has been opened for the purpose of recruiting the health of soldiers after their discharge from hospital. Many of these men are quite unable to undertake any of the usual military duties for some time after their arrival, consequently, some occupation has

to be found for them. It is proposed to make gardens round the huts. May we appeal to the generosity of your readers and the firms who advertise in your paper, for roots and seeds, as we have no money grant to spend for this purpose and our soldiers are, in most cases, in very poor circumstances. Any response to this appeal should be addressed to me as under.—M. W. HORWOOD, No. 3 Company, London Command Depot, North Camp, Scaford.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Destroying Coltsfoot (*H.*).—The only way is to keep cutting off the tops as they appear with a sharp hoe. The more you persevere in the use of this the sooner will it be exterminated.

Soil for Fuchsias and Pelargoniums (*D. G.*).—Fuchsias like a free, light, generous compost, such as equal parts leaf-mould and loam, adding thereto a good portion of silver sand. Pelargoniums like a more holding compost—say, two parts loam to one of leaf-mould and a little sand. A little well-rotted manure may be added to the Fuchsia compost, but the Pelargoniums are, as a rule, better without it. Pot the Pelargoniums firmly, but the Fuchsias somewhat lightly.

Nemesia strumosa (*Inquirer*).—This half-hardy annual may be sown in heat in March and transplanted in May, or sown in the open after the middle of May. It grows from 12 inches to 15 inches high, and produces several stems, each of which bears a head of bloom, but very little foliage. It blooms freely from midsummer to Michaelmas, and if the weather is favourable much later. The colours range from white and pale yellow to deep orange and from all shades between pink and deep crimson. It is very valuable for cutting, two or three spikes in a vase producing a fine effect.

Pot roots of Dahlias (*Dahlia*).—What are termed pot roots are plants that have been grown in the pots through the summer and which remain in them through the winter and until planting time comes. Roots thus preserved are always in excellent condition for planting, so that the term pot root is indicative of some superiority, and marks the difference between the tubers which have had a season's growth and those which were struck in heat at this time of year. Pot roots are generally obtained from the latest struck cuttings, and form the surplus stock of the florists who grow them.

Cinerarias after flowering (*E. D. Daniel*).—After your *Cinerarias* have done flowering you can cut them down to within 2 inches or 3 inches of the soil, and top-dress them with some light, rich mould, and stand them under a shady wall. Keep them moderately moist at the roots, and they will soon send up a number of suckers which can be taken off and rooted in sandy soil in any cool, shady frame, and then potted on. These will make good flowering plants for next season. As a rule, however, we think it best to raise *Cinerarias* from seed annually, except in the case of any particular sorts you may wish to increase.

Tuberous-rooted Begonias (*G.*).—One-year-old tubers make particularly good examples for growing on, and they may be potted first into 3-inch pots, shifting them into 6-inch ones later on. If yours are larger they will, of course, need an increased size of pot at first and also later on. A mixture of equal parts of loam and leaf-mould, or an increased amount of loam according to its consistency, with a good sprinkling of sand, will suit Tuberous Begonias, while, as the pots get full of roots, a little liquid-manure, etc., occasionally is very beneficial. Do not let the plants carry any seed-pods, as these are very weakening.

FRUIT.

Growing an Orange-tree (*Inquirer*).—The small Orange-tree is doubtless one of those grown on the Continent, of which great numbers studded with fruits are every year sent to this country. They are grown in a very light soil, principally composed of leaf-mould, in which they flourish for a time, but after a season or two repotting is necessary, otherwise they become too weak to flower. We should advise you to repot your plant, but before doing so take away as much of the old soil as you can without injury to the roots. When this is done you will probably find that the remaining ball of earth can without difficulty be put into the same sized pot, and if so do not use a larger one, as overpotting must be guarded against. A mixture of equal parts of loam and leaf-mould, or peat, with a liberal sprinkling of sand, will form a very suitable compost for Oranges. It may be grown altogether in a fairly light position in the conservatory, taking care to keep the soil moderately moist, but avoid overwatering. An occasional syringing during the summer is very beneficial.

THE HORTICULTURAL COLLEGES.

THE air is full now of these words, and as a means of teaching gardening they are delusive. They are very often used by men who have no practical means of teaching it. But why a College? That is the worst place of all to teach an art depending almost wholly on practice. From hearing so much talk one might suppose there were not good means of teaching it up to our day, whereas the best means have long existed wherever there were good gardens. To learn the art in any right way one should be able to have variety in the place, and also some beauty of design. If any of these so-called colleges had the means of teaching, it would be nevertheless useless as a place for a youth to learn gardening in any thorough way. That can be only done by working in different gardens.

Gardens differ so much from each other, both as regards plan and contents, that the best way in which a young man can get knowledge of each subject is by going from one to the other and doing what is called journeyman's work. No matter how good the garden he begins in, he should make a study of a variety of other gardens afterwards, and begin at the right end by learning the actual things first, just as a boy sailor does. Books later on may help much.

An instructive example of wrong teaching is afforded by what some would call the higher art of painting. There never were so many means of learning art or so many professors, academies, and shows, and never so much bad art. Young artists have been led to think more of the Academy and the shows than of the thing itself. There must be something to account for the extraordinary difference between a head painted by Franz Hals or Rembrandt and a daub such as one sees in our picture shows, and it is due to the want of apprenticeship in the old way.

W.

NOTES OF THE WEEK.

The Taurian Scilla (*S. taurica*).—This, among the first of the Squills to bloom, has been very attractive for some weeks past. The deep blue flowers, almost as large as those of some of the *Chionodoxas*, are freely borne. It does not appear to be quite so hardy as *Scilla sibirica*, but if planted near a sheltering wall or boulder and in warm soil it will seed freely, and

in time form nice little tufts. Even at this early date seed is developing freely. The half-expanded leaves are prettily marked with bronze on the outer surface, forming a pleasing contrast to the charming flowers.—E. M.

"February Fillydye."—The late heavy rains have not been pleasant, and may be depressing to many, as well as to those who have to do outdoor work, but we think they are very good for flowers and hardy plants generally. It is much better that rain should fall in February than in March and April, when we should be busy in the garden. Nothing is worse for open-air flowers than a very dry winter and spring.

Kerria japonica fl.-pl. in bloom.—To my surprise on March 16th I found a piece of the double Jew's Mallow in fine bloom. It is planted in the basement of the mansion and against a wall facing due south. In addition, the heat from the kitchen, which adjoins the wall, may have something to do with its earliness, but, be that as it may, I have no record of *K. japonica* in bloom at such an early date. On a wall in the garden the shrub will not flower for a considerable time yet.—W. McG., *Balmac*.

Hunnemannia fumarifolia.—This is well worth growing. It is a fine autumn-flowering plant growing rarely more than 18 inches high, and often less than that, its yellow flowers being very showy in September. It comes from Mexico, so it should be given a warm place in the garden. Choose a position where it will get plenty of sun, and on this sow the seed next month, thinning out when ready. It may also be grown in the greenhouse, or raised from seed sown in heat at once and planted out in May or June. Perhaps someone will tell me if there is a simple English name for it. I cannot find one.—E. T. ELLIS, *Weetwood, Ecclesall, Sheffield*.

Planting Christmas Roses.—I, too, think Mr. Jenkins makes too much of the season of planting. I have tried his way and failed, but think it was not wholly the fault of September moving. He does not allow for the effect of a warm calcareous soil. Also in the south some shade is important. The plants never seem in stately health in cold, stiff soils. Roots of near trees and much water are also against them. I am now planting in an old lane cooled by Oak and Ash trees, where the plants will have half shade all the summer. I gave them some lime rubbish to start with. This is the only result of over twenty years' work.—W.

Viola cornuta Haslemere.—I am unaware of the origin of this variety and am inclined to consider it more of a hybrid than a true specimen of the type, because the flowers are much rounder than those of the family in general, and have not the characteristic horn which gives rise to the specific name. Nevertheless, the variety is of much merit, and when it becomes more widely known it will prove an acquisition not only for the flower garden but for the rock garden as well. The habit is compact, while the blooms are of quite a good shade of rose—a novelty in this family. The plants are very free flowering. I may have got the name wrongly, but it seems to be more allied to the miniature Tufted Pansy—Violetta—than to *V. cornuta*.—KIRK.

Forsythia intermedia var. spectabilis.—This shrub is now (February 24th) in bloom, the flower-buds having escaped the persistent attacks of small birds. Many of our best early-flowering trees and shrubs are annually almost ruined by these little pests. It is now a cloud of deep yellow flowers, each more than double the size of those of the old Golden Bell (*F. suspensa*). So freely does this variety bloom that quite half-a-dozen flowers are produced to every one of the latter species. They are also of a deeper colour, while every little sprig is literally clothed with them. It is the most beautiful of the Forsythias, useful alike for the shrubbery or planting singly. *F. suspensa*, with its loose, interlacing, and often drooping branches, looks poor in comparison with this erect and strong-growing hybrid.—E. M.

Saxifraga scardica obtusa.—A rock slope of 2 feet or more across of this good, white-flowered sort was quite one of the best items in the group arranged by Messrs. Waterer, Sons, and Crisp at the Royal Horticultural Hall on March 7th last. White-flowered Saxifrages may be said to be fairly numerous, but it does not follow that all present like effects or that one could well do duty for another. Indeed, it is not so. For example, that named above is very distinct. It also arrests attention, not because of flower superiority—the blossoms are starchy, the petals widely parted—but because of their abundance and peculiar whiteness against unusually dark green rosettes of leaves. In this way and with well-cultivated examples freely grouped the effect is good. That named above is widely removed in habit and flowering from the true *S.*

scardica, a rare and difficult plant from the Balkans, coming nearer to *S. Rocheliana*, though flowering earlier—March being its natural time in southern England. Happily, it is easy to grow and of free habit.—E. H. JENKINS.

Saxifraga Rocheliana lutea.—The varietal name is a considerable attraction, and a good yellow-flowered form of so desirable a plant as *Rocheliana* would be welcome in any collection of choice Saxifrages. The above remarks are made advisedly, inasmuch as nearly all the best of the yellow-flowered Saxifrages have a habit of growth which, while not erring on the side of generosity, are also not a little fastidious at times. *S. Rocheliana*, on the other hand, is not difficult to grow, and the growth is free. There is, however, yet room for a deeper-coloured yellow than we have so far in the variety named above. Its better side is seen during the early days of opening, when the deep primrose-yellow colour is as beautiful as it is distinct. Later the yellow colour pales somewhat and is less attractive. All the same I know nothing like it. Messrs. Tucker, of Oxford, had it quite good at the February meetings of the Royal Horticultural Society.—E. H. JENKINS.

Echeveria retusa for winter blooming.—Some well-grown pieces in good flower, shown at the Royal Horticultural Society's meeting on March 14th, recalled to mind this beautiful winter-flowering plant, which only requires to be more extensively grown for furnishing cut flowers in winter. It is a Mexican plant, and belongs to the *Crassula* family. It succeeds well in an ordinary greenhouse, in which it will begin to throw up its large spikes of beautiful flowers about Christmas, and will generally continue in bloom until the middle or end of March. The flowers remain long in good condition when cut and placed in water. They have a rich waxy appearance, the colour orange-scarlet faintly striped with yellow. The plant itself is easily increased from cuttings, which may be inserted singly in 3-inch pots filled with a mixture of sand and sifted leaf-soil and placed upon a shelf in a structure where a temperature not under 69 degs. is maintained. Such cuttings will speedily root, and may be shifted into 5-inch or 6-inch pots. During the summer they may occupy a cold pit, but they should be placed in the greenhouse early in October. Plants of this description will bloom soon after the middle of December. Any light sandy and not over rich soil will suit them.—P. T.

Hellebores as cut flowers.—The flowers of the Christmas Rose when cut last in water for two or three weeks, but we cannot always depend upon having them, as they come in midwinter, and unless protected are usually marred by the weather. The spring Hellebores, especially the lovely forms of *orientalis* and *colchicus*, having a graceful habit with several flowers borne on long stalks, are even prettier for cutting and need no special arrangement. When first we tried them for cutting, however, they proved very disappointing, and did not last fresh for as many days as the flowers of the Christmas Rose would weeks. Apparently, however, this defect arises from some inability of the flower-stems to absorb water at a sufficient rate to make up for evaporation or to sustain the freshness of the blooms. There is a simple and most effectual remedy, however, which is to split up the base of the flower-stem for an inch or so with the knife immediately before putting the flowers into water, and then the blooms keep fresh for nearly a fortnight if they are required as long.

Saxifraga Haagi.—This fine hybrid, of more than ordinary merit, resulted from the crossing of a couple of yellow-flowered species from Macedonia, viz., *saneta* and *Ferdinandi Coburgi*. In the hybrid the influence of both parents is clearly revealed, the rich, golden-yellow flowers, their shapely form, medium size, and short, sturdy stems, obviously inherited from *Ferdinandi Coburgi*, the free, dense carpet of growth—a great asset in such a case—showing the obvious influence of the free-growing *S. sancta*. Curiously, *S. Ferdinandi Coburgi* is not generally a success unless as a crevice plant or with frame culture, while the other, *S. sancta*, has but little beyond free growth and somewhat of colour to commend it. A combination of the two, however, has provided a plant of unusual beauty and merit, few, if any, so richly golden in colour—Mr. Irving, in "Saxifrages," refers to its flowers as orange-yellow—none more free in growth or more amiably disposed. Hence it is a plant to garden with, more especially when its hardiness and weather-resisting properties are taken into account. It grows freely in gritty loam with good drainage.—E. H. JENKINS.

Variation in plants.—Before a large attendance of members of the Wimbledon and District Gardeners' Mutual Improvement Society, at Queen's Hall, Professor Bateson, Director of the John Innes Horticultural Institution, lately discussed the question of variation in plants. He reminded his audience that the subject was one of great interest to the gardeners of the middle of the 19th century. Not only in connection with indoor work, but for bedding purposes in the formal gardens of that time, variegated plants were in great favour. Now that interest in these plants had declined it was very difficult to procure variegated plants to experiment with. Those procured they were using in an attempt to understand the processes of plant breeding. It was through variation that they were able to get a side-light on the process of heredity in plants, which at present they were unable to get from any other source. In horticulture there were a number of conditions spoken of as variation, but he was dealing with that class of variation which showed the change in the amount of the green matter to which the green-coloured leaves were due. This matter existed in small, round, or flattened bodies inside the cells, and was quite different from the matter surrounding it. He then proceeded to describe the arrangements obtaining in the orderly and disorderly distribution of the matter.

[A very trivial subject to occupy the time of a professor in a horticultural institution! All that variegation usually does for gardens is to disfigure them with ugly colour and often disease.—Ed.]

The Winter Aconite poisonous.—Mrs. Portman Dalton's narrative in GARDENING ILLUSTRATED of March 18th (p. 144) is tragic and also very mysterious, since the poison Aconite is the Monkshood (*Aconitum*) and not the little, so-called "Winter Aconite" (*Eranthis*), which, I believe, we may still enjoy without any danger.—D.

—If this plant has deleterious effects it is well that it should be known, but the note in your issue of March 18th is far from being convincing, and is open to grave suspicion that it is all a blunder arising from the common name of the *Eranthis hyemalis* being "Aconite." For I cannot find either in old Herbals, in Medical Botany, or in books on *Materia Medica* that there is even a trace of Aconitine in this plant. Nor does the

statement that a doctor—and a herbalist, save the mark!—who were called in considered that the patient was suffering from "acute Aconite poisoning" carry the matter any further. For the symptoms of Aconite poisoning do not differ from those met with commonly enough in the final stages of consumption, nor would "acute Aconite poisoning" take a few weeks to kill. In cases of Aconite poisoning no certain diagnosis can be made without finding and separating the poison, and the only way—an easy and certain way—of setting the question at rest would be to get a competent chemist to examine the plant for the alkaloid, which, by the way, is not volatile.—F. R. C. S.

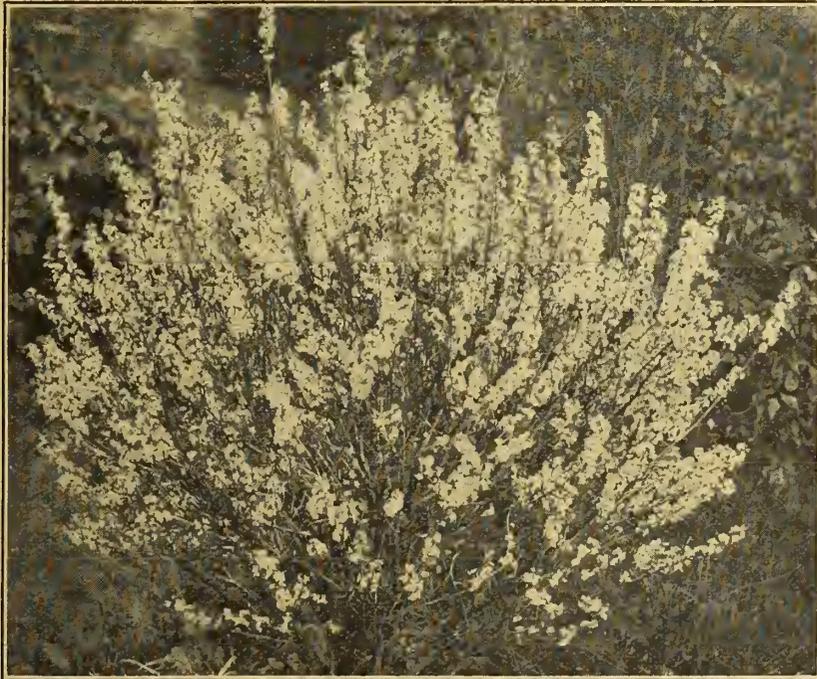

Isopyrum grandiflorum.—No novelty before the Floral Committee of the Royal Horticultural Society on March 7th last excited so much interest as this, albeit the plant obtained no award, the Committee wishing to see it again in a more established condition. Only a solitary flower was open, though even this afforded no small clue as to its beauty. The whole plant—foliage and flower, probably not more than 2 inches in height—gave one the impression at first-sight of a singularly beautiful and distinct small-growing form of *Anemone Robinsoniana* poised on almost thread-like stalk above a small, dense, miniature inch-high tuft of glaucous Meadow-Rue-like leafage. According to Mr. Farrer's description of it it occurs "in shady cliffs, gulleys, and on rock faces in the Alps of China in every shade of lavender to amethyst and turquoise," hence to lovers of alpine there is a great treat in store. The example referred to above was, therefore, doubtless but in the infant stage. It was presented by Messrs. Bees, Liverpool.—E. H. JENKINS.

Hamamelis arborea.—Your correspondent "E. M., Sussex" quotes an article in "Flora and Sylva" in substantiation of his claim for *Hamamelis arborea* as being the earliest to flower. To this my answer is that at the time the article in question was written *Hamamelis mollis* was but little known; indeed, concerning it the writer in "Flora and Sylva" states:—"The new Chinese kind, *H. mollis*, is as yet hardly known in gardens, though to all appearance a plant of value, being quite hardy, of good growth, and the brightest of all in colour." Though at the heading of the article your correspondent assigns specific rank to *H. arborea*, he speaks of it later on as a variety. One is inclined to ask whether he looks upon it as a variety of *H. japonica*? With regard to the dimensions these two Witch Hazels are likely to attain with age, I should say that *H. mollis* is likely to prove more of a shrub than the other, but that size is the only consideration I have yet to be convinced. I note that "E. M.," in his notes on plants in bloom in the open air, does not mention *H. mollis*, so conclude he does not grow it, hence his claim for *H. arborea* as being the earliest and best of the group. If "E. M." will read my short note on page 81 again he will see that I did not claim for *H. mollis* all the virtues, but stated that I should give it the preference over *H. arborea*. With regard to their relative periods of blooming, *H. mollis* is undoubtedly the earlier, as will be borne out by anyone acquainted with the two. I note that "E. M.," while quoting "Flora and Sylva" in support of his assertions, goes out of his way to accuse the author I referred to as having made a mistake. A sentence in my previous note particularly applies—"Where opinions vary so much as in the relative beauty of different plants one must not be too egotistical."—W. T.

TREES AND SHRUBS.

DAPHNE MEZEREUM.

At this season there is no more hardy shrub than the old *Daphne Mezereum*. Not only are its densely-packed flowers charming for colour, but equally so for their sweet perfume. Although it was well known 300 years ago, it cannot be said at the present time to be so plentiful as it ought to be. It is a favourite plant with cottagers, and some of the finest specimens in the country are to be found in small village gardens, where for many years they have been carefully tended. It is by many botanists considered doubtful whether it is truly indigenous to the British Isles, but if not so, it has become naturalised, and is met with wild in several parts of England. There are several varieties of it in cultivation with purple, red, or white flowers. The flowering season of the typical form is February and March, but in mild winters the first blooms may be seen in the closing days of the old year. There is also a valuable

Daphne Mezereum.

variety called *grandiflora*, which commences to flower as early as October and November.

D. Mezereum is a compact, many-branched, erect-growing shrub, attaining in very old specimens a height of 6 feet, but it is usually seen about half that height. It is deciduous, and at the time of flowering is leafless. The flowers occur in short-stalked clusters of two, three, or four together, the clusters being densely packed on those portions of the branches made during the previous summer. The colour is a reddish-purple, but in some forms the purple is scarcely noticeable. The variety *alba* has flowers of a somewhat milky-white, and is equally as desirable as the ordinary purple form. The finest variety, however, in cultivation is the one already alluded to as *grandiflora*, in which the flowers are not only larger than those of any other variety, but the colour is a rich, glowing, reddish-purple.

All the forms of the *Mezereum* are easily grown. They like a moist, moderately rich loam, and flower best in an open sunny position. In autumn the *Mezereum*

again becomes ornamental, its branches being then covered with berries, those of the purple-flowered forms being red, whilst those of the white variety are yellow. The species is readily propagated by seed, which should be sown as soon as ripe; if allowed to get dry it will take two years to germinate. The seedlings mostly follow the parent plant in colour; nevertheless, "sporting" almost invariably occurs, and a few white-flowered seedlings will appear in most sowings of the purple varieties.

FLOWERING CHERRIES.

Of flowering Cherries the Japanese recognise a hundred or more varieties with white, yellow, pure pink to rose-coloured blossoms. Some are small shrubs, others large trees with wide-spreading crowns; some have pendent and others quite erect branches. All are entrancingly beautiful. Cherry-trees grow wild in the woods and thickets throughout the length and breadth of Japan, and they are everywhere planted in vast numbers—in temple and castle grounds, in park and garden, in the streets

branchlets, the whole forming a flattened or flattened-oval crown 20 feet to 30 feet through. The flowers are silvery-pink and are produced in such profusion as to hide completely the twigs and branches. This Cherry was introduced to cultivation by the Arnold Arboretum in 1894, and has been widely distributed. The Weeping Cherry,

P. PENDULA, has flowers similar to the foregoing, to which it is very closely related, but it is a much larger tree, growing 60 feet to 70 feet with a trunk 10 feet to 12 feet in girth, and massive spreading limbs dividing into branches which curve downward and into slender, whip-like, pendent shoots. It was introduced to cultivation by Philip Franz von Siebold, who secured plants for his nursery at Leiden, Holland, from Japan about 1863. It is a long-lived tree, but I have never seen a good example in the Occident. In Japan, and especially in the temple grounds, magnificent examples are common, and there is no more graceful or beautiful tree than this Weeping Cherry. The Japanese called it *Shidare* (Hanging) or *Ito-zakura* (Thread Cherry) on account of its very slender, whip-like, pendent branchlets. The Cherry so abundantly grown in and around the city of Tokyo and whose season of blossoming is made the occasion for a national holiday is the *Yoshino-sakura*,

P. YEDOENSIS. This is a large, quick-growing tree which at its best is 45 feet to 50 feet high, with a trunk from 6 feet to 8 feet in girth and massive spreading branches forming a rounded crown from 60 feet to 75 feet through. The fragrant flowers are larger than those of the preceding two Cherries, and vary in colour from pure pink to white. If crowded together the trees grow taller, but the crowns are narrower and much less shapely. It was introduced to the Arnold Arboretum in 1902, from Tokyo, and the seedlings have grown very rapidly. The most beautiful of all the wild species of Asiatic Cherries is

P. SARGENTI. This is a native of the northern and colder parts of Japan and has large, pink to rose coloured flowers, and the young unfolding leaves are a ruddy-brown. It is a large and long-lived tree, and the avenue at Koganei mentioned previously is of this species and its varieties. Dr. Bigelow sent seeds from Japan to the Arnold Arboretum in 1889, and trees raised from these seeds are now 25 feet high, with a trunk 4 feet in girth and a crown 20 feet through. Nearly all the Japanese Cherries with double rose-coloured flowers are forms of this *P. Sargentii*, and it is the stock on which all of that class should be grafted or budded in order to make them long-lived trees in this climate.

One of the loveliest of these rose-coloured Cherries with double flowers is known in Western nurseries as

JAMES H. VEITCH. The Japanese name for it is *Fugenzo*, and there is also a white counterpart which is styled *Shirofugen*. These two are distinguished from all others of this class in having two tiny green and folded leaves in the centre of the majority of their flowers as is the case in the double-flowered form of the European *P. Cerasus*. Two other Japanese Cherries are

P. SIEBOLDI AND *P. LANNESIANA*. The former has rose-pink double or semi-double flowers, and its leaves are clothed with soft hairs. In nurseries it is sold as "Watereri" and as "Naden." The other species has many aliases, and in its different forms is sold as *P. pseudo-Cerasus* and as *P. serrulata*, names, how-

of the cities and alongside the highways, by pond and by riverside. At Koganei, there is a three-mile avenue of Cherry-trees planted in 1735, by command of the Shogun Yoshimune. Many of the trees are from 60 feet to 75 feet high, with trunks from 10 feet to 12 feet in girth and crowns from 50 feet to 60 feet through, and when in full flower the scene presented is a never-to-be-forgotten one.

As one result of its recent expedition to Japan the Arnold Arboretum has now growing a collection of more than seventy varieties of these Cherries, and in a few years the American public will have an opportunity of appreciating the attractive charms of these plants. Meanwhile the following kinds of proven merit should be grown by all who love a hardy plant. The first of these Cherries to open its blossoms is

PRUNUS SUBHIRTILLA, the *Higan-sakura* or Spring Cherry of the Japanese. This is a low bushy tree, rarely more than 18 feet to 20 feet, with thin ascending-spreading branches and a dense mass of twiggy

ever, to which it has no proper right, and which have proved a great bugbear and hindrance to our proper appreciation of the garden varieties of Japanese Cherries generally. In typical *P. Lannesiana* the flowers are pinkish, but its wild form has pure white blossoms. All the numerous forms of this Cherry have fragrant flowers, and they are mostly white or pale pink. One sort (*grandiflora* or *Ukon*) has clear yellow flowers, and in another (*Gioiko*) the colour is yellow with a green band down each petal. In both the flowers are double. *P. Sieboldi* and *P. Lannesiana*, together with their forms, are trees from 20 feet to 30 feet high, with wide-branching heads, and in Japan they grow rapidly, but are not long lived. One other species of Japanese Cherry deserves mention, and that is

P. INCISA, which is abundant on the lower slopes of Mount Fuji and the immediate vicinity, but is confined to those regions. It is a bush or small tree from 5 feet to 30 feet high, with ascending and spreading thin branches and twiggy branchlets and pale pink to pure white flowers. This Cherry blossoms profusely in a small state, and is the only kind the Japanese dwarf and grow in pots, and on this account they designate it the *Mamezakura*—Dwarf Cherry.

GRAFTED ON WRONG STOCK.—In the Occident we have not been very successful in cultivating the double-flowered forms of these Japanese Cherries, and from information gained during my recent visit to Japan I am convinced that our want of success heretofore has been due to the fact that for our climate they have always been grafted on the wrong stock. All the single-flowered sorts of these Japanese Cherries fruit freely with us and should be increased by seeds, for seedling trees of these Cherries grow more freely and more satisfactorily than those raised by other means. All the double or semi-double flowered kinds should be grafted or budded on *P. Sargentii*. If this be followed I make bold to say that these Cherries will thrive as well, grow as freely, and live as long as they do in Japan.—E. H. WILSON in *The Garden Magazine*.

NOTES AND REPLIES.

Skimmia japonica.—Intending planters of shrubs ought not to overlook the claims of the *Skimmia*. Apart from its brightly-hued fruits, the blooms, freely produced in terminal trusses, are delicately perfumed, while the shrub is, in itself, symmetrical. It should be borne in mind that in order to secure berries the different sexes of the shrub must be planted. If the female form alone is used there will be plenty of bloom but no fruits, but if planted in the proportion of one male to five or six female plants a good crop of berries is assured.—KIRK.

Pieris floribunda.—This choice evergreen shrub is now in flower. January being so mild, the first few flowers opened in that month, but the severity of February checked them, so that now (in the middle of March) they are barely at their best. Being a compact grower, it is very suitable for the rock garden or in beds of choice shrubs. It thrives best in a soil containing much sand and leaf-mould or peat. The flowers are borne in dense racemes, and last well on the plant or when cut.—C. TURNER, *Highgate, N.*

The Oso Berry (*Nuttalia cerasiformis*).—This was recently noticed in bloom in a neighbouring garden. In appearance it is not unlike the common Bird Cherry (*Prunus Padus*), but of more slender growth, and apparently not so rampant. In open winters the blooms, produced in racemes along the entire length of the shoots, are often in evidence during the early days of March. *Nuttalia cerasiformis* is quite hardy in this country, although, judging by the specimen noted, which has been planted for some years, it does not grow very fast.—W. McG., *Balmoe*.

VEGETABLES.

RHUBARB FAILING.

I SHALL be pleased if you will tell me the cause of and, if possible, a remedy for the following—Last autumn I purchased and planted in the open about twenty roots of Rhubarb. The stalks began to grow during the mild weather about the third week in January, and I was expecting an early crop, until one morning about ten days later I found two stalks bent and lying on the ground. From then until now scarcely a morning has passed on which I have not found one or more stalks similarly bent. Altogether I have lost about forty stalks in this way. On close examination, I find that the stalks apparently become weak and partially shrivelled up at a point either just above the crown or at a point 2 inches or 3 inches above it. About two days later the whole stalk shrivels up. Some are affected when 2 inches or 3 inches high, and some when 8 inches or 9 inches high. None, however, have reached a height of more than 9 inches, except on two roots. The stalks on these two roots are perfectly healthy, and, although growing among the others, none have been affected. The stalks do not break off—they only bend. It is not caused by frost or wind, as the weather was calm and very mild from the time they began to grow until after they were first affected.—W. L., *Camborne*.

[The probable cause of the Rhubarb stalks shrivelling in the manner described is that the crowns, having erroneously been transplanted in autumn, they have not, as we shall presently explain, recovered sufficiently from its effects to enable them to support growth beyond a certain period. The present is the best time in the year for lifting, dividing, and transplanting Rhubarb crowns, as new roots are then quickly emitted, which soon multiply, and by the end of the season the crowns become thoroughly established. The result of autumnal planting is that the roots, owing to their peculiar construction, invariably remain inactive until the spring or warmer weather arrives. If in the meantime a spell of mild weather occurs, such as was the case in the latter end of January and early February last, the crowns start growing, and continue, weather permitting, to do so until the stored-up nutriment contained in the crowns is exhausted. Then, when, so to speak, no further supplies are forthcoming, owing to the absence of active roots for the growths to draw upon for support, they collapse and die away. The fact of two crowns having yielded stalks in a satisfactory manner furnishes proof that since planting took place new roots in their case have been formed. There is nothing to be done but wait patiently till another season comes round, by which time the crowns will have become well established and will then doubtless yield a full complement of stalks.]

NOTES AND REPLIES.

Spring digging.—It is always advisable to get vacant ground turned over as early in the season as possible, and when this can be done the soil ought to be left as rough as possible. In the case of breaks which have to be left until spring different treatment is necessary. In the course of digging, the soil ought to be broken down as finely as possible, more particularly when the staple is clayey or heavy. If left rough the searching winds of spring rapidly dry out the surface moisture of the clods, which harden almost to the consistency of bricks. Should a portion of such a break be required during a dry spell, it is almost impossible to reduce the surface to a sufficiently friable condition, so that when spring digging is necessary this fact ought to be kept in view. If the surface of such a break is, owing to circumstances, left rather rough, the best time to break it down will be found to be immediately after a brisk shower. Then the clods may be broken up quite easily with wooden rakes.

GARDEN FOOD.

NOTES AND REPLIES.

Wholemeal bread.—I am having wholemeal bread made by Sir Henry Thompson's recipe. Do you realise how much nicer bread is broken, not cut? Of course, one breaks it at dinner, but there it is only an accessory to meat or whatever it may be; but at breakfast, with butter or honey, it has its own importance. It is easier to go on cutting it about with the knife, but broken you seem to get the whole value of the flavour and aroma. The matter came to mind when looking on a parcel of old journals and sketches of many years ago, when I was for part of a winter in the Turkish island, Rhodes. Our servants were a Jew and a Greek woman. When we asked for bread at dinner the Jew took the loaf—a flattish cake such as we make of wholemeal—and broke a piece off. They will not touch bread that has been cut.—J.

[No doubt it is best broken, but the thing to be sought most as to wholemeal, the best of breads, is to get rid of yeast in making it. It destroys the natural taste of the wheat and makes bread a source of discomfort and disease. The Americans have got over the difficulty with their white flour by the aid of their small gem pans, but how to bake wheaten meal without yeast is still to be done.—W.]

Celery Cabbage.—I notice your editorial query as to what is meant (page 134) by "The Celery Cabbage." Do you think what we know as "Seakale Beet" is referred to? It rather looks like it to me. I always use the mid-rib of the leaf in the same way as ordinary Seakale, and find it quite agreeable, the very slight Beet flavour being pleasant. The green part should be mashed very fine and served, as Spinach, with cream and butter.—C. B. R., *Bafford Grange, Charlton-Kings*.

—Although I do not recognise the name, I think there is no doubt, from the description, that this new vegetable is the Chinese Cabbage known as "Pè-Tsai." This can be used in the various ways described in the note, and the centres make an excellent salad. The growth is extremely rapid, but it is not advisable to sow it very early in the season, as there is a great tendency to run to seed if sown too soon. I grew a few rows of this vegetable last year, and the seed was not sown until July 15th. The Cabbages were ready to cut early in October, or in from eleven weeks to twelve weeks after sowing. I know of no vegetable which is so rapid in growth and produces such a large plant in so short a time. It occurred to me that it might be a valuable crop for farmers on account of its rapidity of growth and the time of sowing. Where roots have failed this might be put in from the middle to end of July, and should produce a very useful crop for dairy purposes or cattle by the middle of October. I have sent a supply of the seed to one of our Agricultural Colleges and they are testing it this year. In appearance the plant seems to lie midway between a Turnip-top and a Cabbage. It makes a large heart which, in good ground, weighs several pounds each. I have much pleasure in enclosing a small packet of seed for trial should you be interested and wish to grow it.—F. B., *Springfield, Northampton*.

Leeks.—At this date (February 26) the contrast between Leeks raised in heat and grown in trenches and those sown out-of-doors and transplanted is worth noting. The former are now bolting, while the latter, with about 10 inches of blanch and 1½ inches in diameter, are in excellent condition, and may be relied upon for quite two months still. The moral is obvious.—KIRK.

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

BREADTH AND REPOSE IN LANDSCAPE.

THE most evident mistake made in design of work is the want of repose or breadth which is seen in so many parks and pleasure grounds. In the Home Counties one can scarcely see a piece of modern park land without the trees being in rings and in dots here and there spoiling all the breadth and simplicity of the scene. Such planting spoils landscape effect and does no good to the trees, as the dots are too small for shelter. The best way by far is to keep such green spaces open and plant broadly ground that is no good for Grass

The planting without thought of rampant evergreens is a common evil in British gardens. Evergreens are often planted where people do not see what they may become after years of growth. Important views are shut out by these evergreens, and even the house itself may be hidden by their ugly masses. One sees the same thing in public gardens, where it should be important to keep the scene picturesque and preserve any natural charm of the ground, instead of over planting it.

In France it has been a common practice to mar any grace of public squares and gardens by using them as a display ground for the efforts of the sculptor; but the French now begin to see this mistake,

pathways for cleaning, feeding, and various purposes that need not be named.

In the garden itself certain malformed trees are used by designers of architectural turn to give points—the Irish Yew, close-growing Juniper, and various hideous sports of the Western Arbor-Vitæ. These are often used from the fatuous idea that they are old and right in the old English garden—the fact being that they are all modern rubbish that can do no good to any garden planting.

It should be borne in mind that the garden is but a patch in many a country place. It is only when we leave it we begin to see the real opportunity for landscape pictures in field, park, or woodland. Among the most interesting landscapes

Riverhill, view into weald.

or plough. In such places trees can grow nobly. Sometimes one sees a single Pine spoiling the middle of a lawn. The lawn-like beauty of park or garden is the most precious thing we have for giving us air, sky, and space, and the grouping and massing are the right way.

How to remove the defect in park-like places is difficult, but one may occasionally unite two or three groups into one whole, and so get rid of the spotty effect, but the best way often is to remove the dotted trees altogether and replant. It is the nature of trees on mountain or steppe to grow together and protect each other, and in our wind-swept isles and in many others it is often important to plant in the teeth of the worst wind, and close planting should be the rule.

and to cry out against it. It is now proposed to remove these statues into one great statue cemetery, where those who admire them might worship.

In our own parks there is a beginning in the same direction. Close to Hyde Park Corner there is a sort of fountain out of place, which spoils a little lawn. Large memorial confectionery groups ought not to be allowed to break up the spaces in the parks. Lately, I am told—I have not seen it—the fantastic idea of a playwright has been embodied in stone in Kensington Gardens. If each succeeding decade is to see outrages of that sort committed what will eventually become of the repose and quiet grace of parks?

An effective way of destroying repose in a public garden is the caging of animals there. This leads to ugly shanties and

in Britain are those in Kent, looking from high ground into the weald, as in this view at Riverhill. W.

Lobelia Barnard's Perpetual.—Lobelias are indispensable where summer beds are to be filled, and some little attention might be directed to the choice of suitable varieties. Much depends on the type of Lobelia desired, some preferring the dwarf, erect sorts, like Blue Gem, others considering such Lobelias as *L. speciosa*, of a trailing habit, to be superior. The dwarf varieties are too stiff and formal, while the spreading sorts are apt to overrun Grass edges and suffer mutilation when the lawn-mower is being used. On the whole, therefore, it would seem better to employ an intermediate type of Lobelia for edging. Such a variety may be found in Barnard's Perpetual, perhaps one of the best Lobelias for the purpose, while it is

equally useful for vases or for window-boxes. The colour is a pleasant shade of blue, the plant is very free flowering, and while it does not encroach unduly it never has the stiff, artificial look of the dwarf Lobelias.—KIRK.

NOTES FROM ASHBOURNE.

OLEARIA AVICENNIFOLIA.—Hook f. Hand-book N.Z. Fl. 127. Kirk, Forest Fl. I., iii.; Students Fl. 274. Eurybia avicenniaefolia, Hook f. Fl. November 2nd, 1, 120. Shawia avicenniaefolia, Raoul, Chron., 19. After reciting the above list of authorities I may say that I obtained the shrub under the above name from Sir Frederick Moore, of Glasnevin. It is abundant throughout the south of Stewart Island up to 3,000 feet.

THE SERBIAN SPRUCE (Picea Omorika).—This is one of the beautiful, rare, and disappearing Spruces now dying out and very difficult to obtain. In the "Manual of Coniferæ" it is stated that it has a very restricted habitat on the mountains of south-west Serbia and their prolongation into the neighbouring States of Bosnia and Montenegro. Willkomm is of opinion that P. Omorika had formerly a more extensive distribution, but became exterminated for the sake of its timber, and that it has been preserved within its present narrow limits by their greater inaccessibility. It is a fine-shaped, close-growing conifer and a decided acquisition, at all events, in the south of Ireland, where it thrives well. I have obtained three more good specimens from Messrs. Cheal, of Crawley.

A NEW PRIMULA.—A lovely Primula has flowered here. It was raised from *Primula viscosa* crossed with *Primula marginata*. Its colour is aniline-blue margined with a clear, delicate, white line slightly dotted with white tomentum; clear white eye. The flowers, sometimes seven upon each whorl, are carried on stalks 3 inches high, and are each $\frac{3}{4}$ inch in diameter, with the white eye 3-16 inch diameter, five petals to each flower, rounded, with a small dentation at the centre of each edge. The leaves are each 2 inches long and $\frac{3}{4}$ inch wide, box-green in colour, covered with tomentum and margin white, upper half of the leaf serrated. It is a remarkable plant, and I trust will be shown next spring at the Royal Horticultural Society's show.

NARCISSUS R. II. BEAMISH.—I have also a Daffodil raised here which may be useful. It is described as follows in the Daffodil Year Book, 1914:—

"Royal Horticultural Society of Ireland Exhibition, April 15-16, 1914.

"They had, however, one new seedling which far and away eclipsed aught else in the show, and this was a bunch of N. R. II. Beamish (bearing the name of the raiser), a giant of the big trumpet tribe, with a solid-looking white perianth and pale sulphur trumpet, a grand flower, and, judging by the robust foliage, as well as by the big, stiff stems, of ultra-vigorous habit."

Since then I have obtained one or two more good things of which we have hopes.

The weather has been unusually cold here, but as soon as spring really breaks there is much to be done in the rock garden, a new moraine of limestone to receive various treasures, including that delightful and rare sun-lover *Cyananthus incanus*, easy, comparatively, to propagate in a cold house, but difficult to preserve over the winter out of doors on account of the damp. It is worthy of trouble when one sees it covered with its deep blue flowers in the summer and autumn.

R. II. BEAMISH.

ECONOMY IN THE FLOWER GARDEN.

WHERE, under existing conditions, it is not deemed advisable to spend anything on plants or seeds, it will be well to have a look through the flower garden as soon as the ground is workable to see what can be found to fill gaps. Where, for instance, Cornflowers and Antirrhinums were flowering in the summer of 1915 it is probable that batches of seedlings may be found, and these, being sturdy and hardy, will come away quickly when transplanted to other quarters. Also, later, many seedlings will appear where tall and dwarf *Nasturtiums* were grown. These may require the shelter of a cold-frame for a time, but will make good stuff for late planting. Seedlings of the dark-foliaged variety with scarlet flowers, as represented by a sort known as Empress of India, can be reserved for the front of borders, where they can be associated with Pinks and plants with foliage of a similar hue. In addition to the seedlings there are many favourite hardy plants that produce offsets with great freedom, notably some of the tall Campanulas, both white and in many shades of blue, *Chrysanthemum latifolium*, Phloxes, Starworts, and the like, such offsets being strong and producing fine flowers. If the division is left till March it is worth going to a little extra trouble with the process in the way of careful removal of the soil and severance from the parent plant; also quick and careful replanting, especially if at the time the weather is very dry, with cold, biting winds. This, also, should be specially noted in the case of border Carnations which have remained hitherto where they were layered, the tiny rootlets are very tender and resent, alike, rough handling and long exposure. Where there are a few nice clumps of Funkias inspection will probably furnish some nice side pieces that can be removed without injury. *F. ovata* and its variegated form give something in the way of flower and foliage quite unique in hardy flowers. They also make capital tub plants, and may remain undisturbed for several seasons if they are given an annual top-dressing and liberal supplies of liquid manure during the growing season. E. B. S.

Hardwick.

NOTES AND REPLIES.

Helenium Bollanderi.—Many hardy plants may now be lifted, divided, and replanted, and among them the *Heleniums*. One of the most showy is *H. Bollanderi*. Quite small pieces in a season or two will make good clumps, and being of an intermediate height the variety is useful for the foreground of a border. The flowers are large, of a clear yellow, and, having long stems are well adapted for cutting.—W. MCG.

The value of Grass from the lawn for manure.—For many things there can be no better manure than the cut Grass from the lawn, deposited in a heap and kept until spring. One of the best growers of Asters I know uses nothing else and obtains results not easily equalled. He keeps the mowings in a heap, adding no other material, and in spring this is in the best possible condition for applying to the beds of Asters.—Ess.

Our readers will greatly oblige by ordering their weekly copy of GARDENING ILLUSTRATED in advance from their newsagent, as this will prevent wastage in printing. Moreover, the Government is reducing the supply of paper, and, hence, the utmost economy is necessary in this particular. Persons who experience difficulty in getting the paper locally are advised to write to the publishing offices, 63, Lincoln's Inn Fields, London, W.C. The postal subscription is 6s. 6d. for the year, 3s. 3d. for the half-year. The paper is posted on Tuesday night regularly to all postal subscribers, and should reach them on Wednesday morning.

INDOOR PLANTS.

PERPETUAL-FLOWERING CARNATIONS.

THESE are gaining in favour with the public every year. There are, however, many who regard them as being beyond their skill. It is possible to treat them too well—that is, keep them in a very warm structure, unduly restrict the ventilation, pot them in too rich soil, and over-feed them. I use ordinary turf, lifted when a long garden path was to be formed. This turf was stacked and at the end of a few months it was fit to use. There was scarcely any fibre in it. Furthermore, very little leaf-soil was used, only coarse road-grit. From the rooted-cutting stage to the season of flowering, the plants grew and rooted in it like Couch Grass. A gardener I knew who made up fancy mixtures had trouble with the plants throughout the summer, and in the autumn, when there should have been abundance of roots in the pots, there were very few. The soil had been poisoned with artificial and liquid manures. He could not understand how it was that my plants were so large and robust. I do not give any artificial manure till the plants are well rooted in their flowering-pots.

They are still grown each year in the same kind of soil, but are improved by the addition to it of old mortar-rubble, broken bricks—pounded—and wood ashes, used at every potting as follows. To a bushel of loam a 5-inch potful of wood ashes, a 6-inch potful of old mortar-rubble, and a similar quantity of pounded bricks are added. Broken bricks and small lumps of old mortar are put in for drainage. In this mixture the plants root very freely.

The present is a good time for a beginner to start with a collection of plants. I root the cuttings, taken off the flowering-stems about half-way up, in pure sand, in a box 9 inches deep covered with glass. Those who cannot do this should purchase young stock in small pots ready for re-potting into 3½-inch ones. When they are well established in these pots break out the stem from the axils of the leaves about six joints above the base of the plant, then the resultant side shoots will form the base of a sturdy plant. The final potting should be made into 6-inch and 7-inch pots. Never allow the soil to get very dry. Keep near the light and ventilate freely when the weather is suitable, placing in cold frames about the middle of May and in the open air on a firm bed of ashes during July and August. Transfer them to their winter quarters early in September.

An amateur who has never grown these plants before may begin with the following varieties:—**PINK:** May Day, Baroness de Brien, Enchantress, and Lady Northcliffe. **WHITE:** White Perfection and White Wonder. **RED:** Britannia and Beacon. **CRIMSON:** British Triumph and Princess Dagmar. **YELLOW:** Yellow Stone. **FANCY:** Benora, Cinnabar, and Royal Purple. As success comes and experience is gained, the list can be easily added to.

BOURNE VALE.

Begonia manicata.—After the various winter-flowering Begonias are past their best the blossoms of this old Mexican species are much appreciated. In size they cannot be compared with those of many of the newer garden forms, yet being borne very freely they make a goodly show. The flowers, borne in large branching panicles, on scapes each 2 feet to 3 feet high, are of a pleasing shade of light pink. There are two varieties—

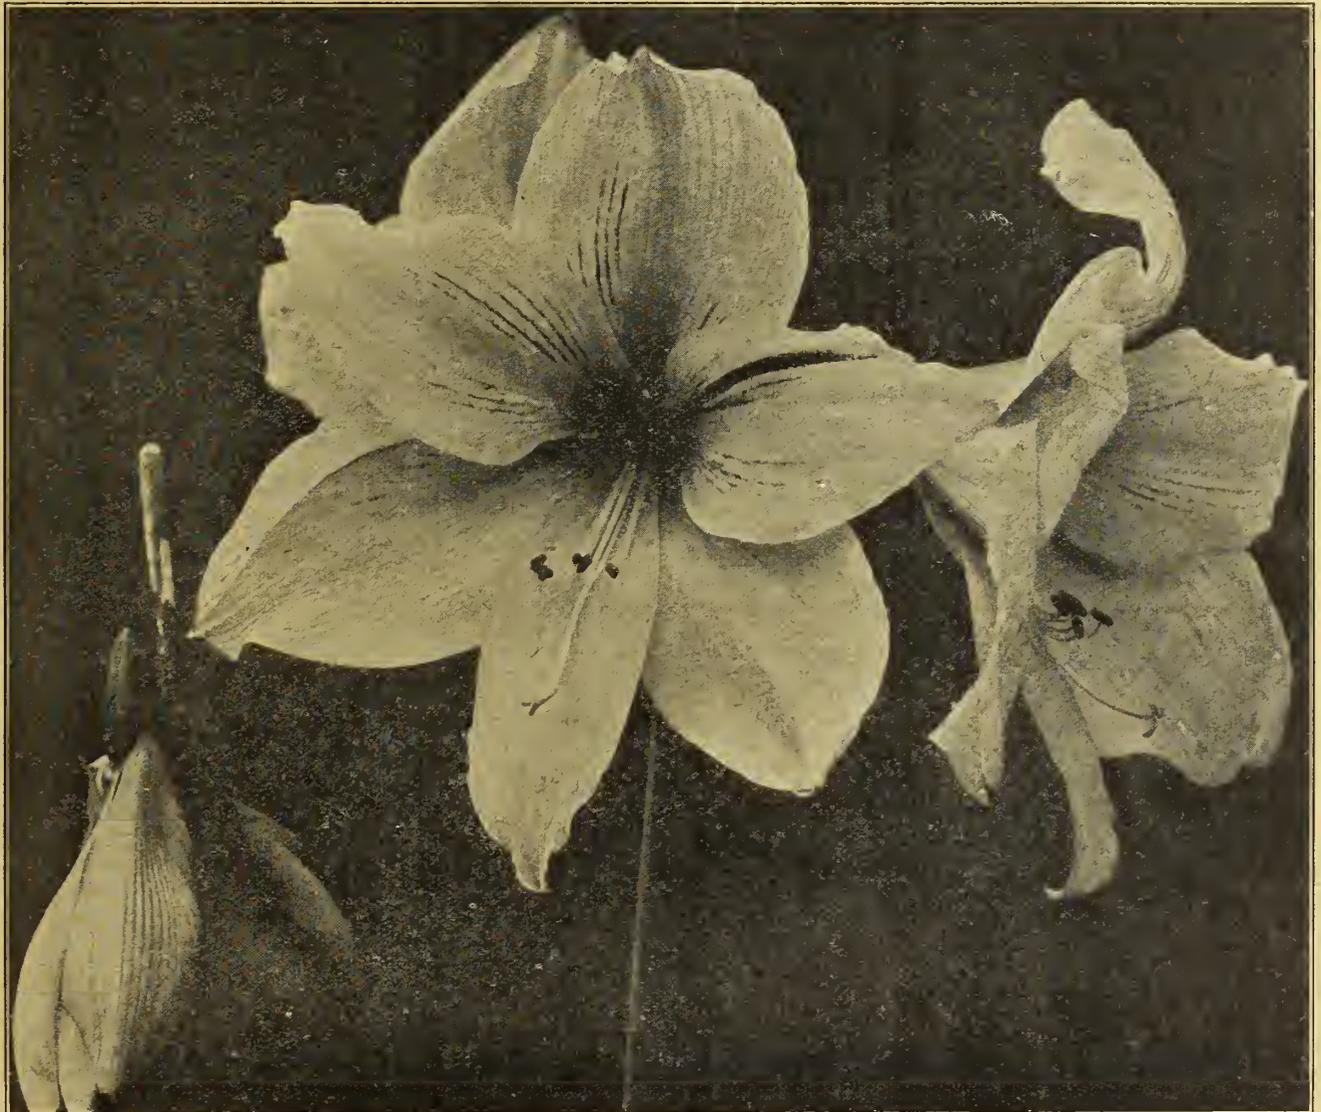

nureo-maculata, in which the leaves are blotched with creamy-yellow, and crispa, or cristata, whose foliage is crisped in the way of some of the Kales. This Begonia needs a temperature above that of an ordinary greenhouse, indeed that which is generally referred to as intermediate. It may be increased by division, from cuttings of the stems, or from leaf cuttings.—W. T.

HIPPEASTRUMS FROM SEED.

AMARYLLISES are readily increased by means of seed, and large numbers are obtained in this way. Crossing is easily carried out and the seed does not take long to ripen, while if sown at once

added a fair sprinkling of rough silver-sand, which should be thoroughly incorporated with the rest of the soil. The pots or pans must be well drained and filled to within half-an-inch or less of their rim with this compost. It is best to insert each seed edgewise into the soil. By some the seed is sown pretty thickly, the seedlings being pricked off as soon as the young plants are large enough to handle; but where room is available the better way is to place the seeds in the pans at a sufficient distance from each other to allow the young plants to develop a couple of leaves or so before it is necessary to disturb them, and then they may be potted off into thumb pots—that is to say, small

6 inches in diameter. They may be rested altogether in a cooler structure than that in which they have been grown previously, and if dry and in good condition a minimum temperature of 50 degs. will suit them well. If the plants have made satisfactory progress the strongest may be expected to flower in about two and a-half years from the sowing of the seed, but most of them will be a year later than this; in fact, those that flower early will often improve as they gain strength. By some the seedlings are planted out in a prepared bed in a house or warm pit, and where large quantities are grown a good deal of trouble is saved by treating them in this manner; but in many places there are no facilities for this, when, of course,

A seedling Hippeastrum.

thrifty little plants quickly make their appearance. But for flowering it is necessary to wait for years. As with the raising of other plants, there is always the pleasure of anticipation, and though the seedlings may not be superior to existing varieties, yet they are all good decorative plants, none the less useful because they do not exactly conform to an ideal flower.

The seed ripens about the latter part of July or in August, and if sown at once it quickly germinates, whereas if kept till the spring, the results are by no means so certain. The seed may be sown in pots or shallow pans. A suitable compost consists of equal parts of good yellow loam and well-decayed leaf-mould. To this must be

pots about 2½ inches in diameter. For this potting the same kind of compost may be used as that in which the seeds have been sown. If the seed is sown as soon as ripe, and placed in the stove, the young plants will be sufficiently advanced to pot them off early in the autumn, when they should be again returned to a light position in the same structure and kept in a growing state throughout the winter, for it is not necessary to rest them at that period, as is done in the case of old-established plants, and indeed it is now pretty generally agreed that the best way is not to rest them till the autumn of the second year, by which time they will be good established plants in pots 5 inches and

pot culture is the more convenient. Pot culture also possesses this advantage, that any particularly choice forms can receive special attention.

Saving seed of Chinese Primula (T. G).—To obtain seed of the Primulas stand the plants on a shelf close to the glass in a cool greenhouse by themselves to prevent insects fertilising the blooms that it is desired to preserve true to character. Do not give the plants an excess of moisture at the roots, and, of course, none overhead, keeping the blooms perfectly dry. With a camel's-hair pencil touch the pistil or stigma in the centre with pollen from the stamens, thus producing artificial fertilisation. Limit the number of seed pods on each plant to a dozen, removing, of course, the smaller with a view of adding strength to the remainder. The seed should not be gathered until thoroughly ripe, and may then be sown when desirable.

ROSES.

THE PRUNING OF ROSES.

Most Rose growers agree that to obtain the best results it is necessary to prune. In pruning, the first thing to do is to entirely remove all shoots that are either too old or too weak to produce a fair quantity of blossom, leaving nothing but really strong young growths. It is particularly desirable to keep the centre of the plant open, so that there may be a free circulation of air and light about the shoots that remain. An unpruned tree may give a greater number of flowers or sprays, but a properly-pruned plant will give, not only finer individual blooms, but a better effect also in the mass. This preliminary thinning out will be very beneficial even in the case of the various summer-flowering Roses, such as the Austrian and Persian Briars, Scotch Roses, Moss, Rugosa, Damask, Hybrid Briars, and Rose species, but no further pruning is necessary. The perpetual-flowering Roses need different treatment according to their habit, vigour, and the purpose for which they are grown. The Hybrid Teas and Hybrid Perpetuals are treated similarly, excepting that the latter, being hardier, should be pruned a week or a fortnight before the H.T.'s, the middle of March being about the best time to make a start, or towards the end of March in the Midlands and North. The more rampant of these classes, such as Hugh Dickson, J. B. Clark, Frau Karl Druschki, Florence H. Veitch, Chas. Lefebvre, and George Dickson, after having been thinned out need only have the remaining growths tipped if for garden decoration, or if grown for exhibition the young shoots should be cut down to within eight eyes or ten eyes of the base. Varieties of medium growth, such as Fisher Holmes, Gen. McArthur, Victor Hugo, Lady Ashtown, Betty, Mme. Abel Chatenay, and others, if pruned lightly, will develop into good-sized shrubs and be very effective in the flowering season. In most cases, however, it is advisable to cut these more severely, say to four eyes or five eyes from the base of the shoots. This will encourage the plants to send up fine young basal growths, resulting in more youthful, healthy bushes and a more compact display of blooms. The weakest of the H.T.'s and H.P.'s will need even closer pruning to encourage the production of new and stronger shoots, two or three eyes only being allowed to remain in the case of such sorts as A. K. Williams, Chateau de Clos Vougeot, Horace Vernet, and Edward Mawley. No definite rule can be made, for a variety may grow far more vigorously in one district than in another, and must be pruned accordingly.

The pruning of Teas and Chinas is delayed until April to escape the late frosts. Varieties like Mrs. H. Stevens, Harry Kirk, Peace, and William R. Smith, which produce fairly stout shoots, may be pruned like the medium-growing H.T.'s. The small-wooded, branching growers, such as Betty Berkeley, Corallina, Souvenir de C. Guillot, Comtesse du Cayla, etc., are lightly pruned, the lateral shoots only being cut in to three eyes or four eyes. Maman Cochet, The Bride, Mrs. E. Mawley, and other purely exhibition Teas are cut in hard if one expects to obtain first-class show blooms. Climbing Roses of all classes should have been well thinned out after flowering, and where this has been neglected it should be done at once, before the young growths are long enough to be damaged in handling. A well-thinned climber, whether H.T. Noisette, Wichuraiana, or multiflora, will be more

effective when in bloom than one that has been neglected. After pruning, collect and burn all the trimmings, especially in gardens that have been troubled with any of the numerous pests that attack the Rose. It is also most important to use sharp cutting tools, but if secateurs are preferred use those which have two cutting jaws.

NOTES AND REPLIES.

Rose-beds.—The use of any light-rooting plants for surfacing the Rose-beds during the summer months is in no way inimical to the Rose. Many Rose gardens lose much by the beds being too thinly planted, and the display of flowers marred by the unsightly manure and bare ground below them. Pansies are very suitable for covering the surface, and with that idea in view I am raising a quantity of seedlings in distinct colours. The seedlings, though a little later in coming into flower than plants raised from cuttings, will be in bloom by the end of June or early in July. To be successful in raising seedlings the seed should be sown thinly and evenly in boxes filled with light soil. When strong enough prick the seedlings out into a frame of rich, moist, sandy soil, giving each plant plenty of room to develop, and plant out as soon as large enough. The plants should be gone over frequently during the summer, removing all decayed flowers and seed-pods. Afford water during dry weather and the plants will continue to bloom throughout the summer.—F. W. GALLOP.

ORCHIDS.

CALANTHES.

For the last few weeks the bulbs have been resting, and when growth begins the annual repotting should be attended to. If not already done the bulbs should be turned carefully out of their pots, all the old soil removed, and the roots cut back to within $\frac{1}{2}$ inch of the bulb. This little tuft will hold them in position in the new compost. Ordinary flower-pots are filled to one-third of their depth with drainage material, over which is placed a thin layer of Sphagnum Moss or rough loam to secure perfect drainage. The bulbs are graded, the largest examples being given a pot 6 inches in diameter, and the smaller ones pots in proportion to their requirements. Some advocate putting several bulbs into one pot or pan, but where the space can be afforded the best plan is undoubtedly one bulb one pot. The rooting medium should consist of three parts of the best fibrous loam, with most of the fine particles removed, and one part Osmunda fibre cut up tolerably fine. If the loam is deficient of fibre a little more Osmunda fibre may be added, and where the former is poor in quality some dried cow-manure will be helpful, but it must be broken up fine. Thoroughly mix the ingredients and make the soil warm before the repotting begins, or the new shoots may receive a chill. The growing point is arranged in the centre of the pot, and the soil is made moderately firm. When the potting is completed the new growth will rest on the compost, which should be just below the rim of the pot, to allow space for watering.

For Calanthes the orthodox Orchid-house is not necessary; the plant stove, if not too lofty, a Cucumber-house, or any similar structure, sufficing if the requisite temperature can be maintained. This, during the growing period, should never be lower than 60 degs. Fahr., but as the season advances and the sun increases in power so may the temperature rise

10 degs. or 20 degs. When the repotting is finished the plants are arranged near the roof glass, placing them upon inverted flower-pots if necessary. For several weeks very little water is required; in fact, the soil must be kept on the dry side until the roots are fairly active, but the atmosphere should be moist, and an occasional syringing between the pots may be practised. When growth is well advanced, and the young leaves begin to unfold, copious supplies of water can be afforded, this treatment being continued until the pseudo-bulbs are fully developed. In the early stages of growth a thin shade will be needed to protect the tender foliage from the direct rays of the sun, but later on the plants will benefit from more sunlight if due attention is paid to ventilation. When the weather is hot a light spraying overhead may be given, but it must be done sufficiently early for the leaves to dry before sunset. Each afternoon the house must be closed early, according to the weather, giving the stages and floor a thorough sprinkling with water. As the bulbs approach maturity the amount of atmospheric moisture is gradually lessened, and a little more air may be admitted, especially from the top ventilators. To secure the best results Calanthes must be given generous treatment throughout their growing period, and when at rest they ought not to be placed in a house where the temperature falls below 50 degs. or 55 degs. F. Calanthes are useful for cutting, when they can be utilised in a variety of ways.

The most popular varieties are C. Veitchi (with rose-coloured flowers), C. Harrisii (pure white), C. vestita rubro-oculata, C. Wm. Murray, and C. Regnierii, which flowers a few weeks later than the others mentioned. B.

TRICHOPILIAS.

(REPLY TO ORCHID LOVER.)

THESE do well in the intermediate-house or where the average temperature is 60 degs. F. There are about fifteen species, but those mentioned below are the best from the garden standpoint.

T. SUAVIS.—Discovered in 1848, bloomed for the first time in this country in 1851. The flowers are large and fragrant, with creamy-white sepals and petals spotted with pale rose, while the showy funnel-shaped lip is more or less spotted and blotched with rose-pink. It is the best of the genus.

T. FRAGRANS has white flowers with the exception of a pale yellow spot near the base of the lip. The variety *T. f. nobilior* is a little larger than the type, the flowers purer white, and the yellow spot is also enlarged. Other desirable kinds are *T. sanguinolenta* and *T. coccinea*, of which there are several varieties.

CULTURE.—Trichopilias are not difficult to grow provided the repotting is carried out when roots appear at the base of the new growth. The compost is made up of good fibrous peat and Sphagnum Moss, but if the former is scarce a suitable substitute is Osmunda or Polypodium fibre. Pans without side holes are excellent receptacles, and if a wire handle is fixed they may be suspended from the roof glass and the plants will benefit by the extra light, especially during the autumn and winter. Good drainage is needed, and care should be taken when repotting so that the pseudo bulbs are not buried in the soil. During active growth a moist position is needed, and the rooting medium must be kept damp, but directly the pseudo bulbs are fully developed a less quantity of water will suffice.

FRUIT.

PEAR MME. DU PUIS.

This is a fine Pear of medium size. The colour is a smooth russet brown, seamed with golden-yellow towards the stalk, and the shape is well shown in the illustration. The flesh is melting, very juicy, and refreshing—equal to any Comice I have ever tasted, but not quite so large. It is usually at its best from the end of November till Christmas. The trees, which are five-branched cordons, are growing on a wall facing south, in which position they are moderately vigorous, very fertile, and clean in growth.

E. M.

PREPARATIONS FOR GRAFTING.

WHERE the re-grafting of Apple and Pear trees is contemplated it is high time the preparatory measure of heading back the trees was carried out before the sap becomes too active. The practice of re-grafting is an excellent way of renovating

of Pear-trees to the test. Second and third rate varieties of Pears, such as Beurré Clairgeau, B. Boss, B. Bachelier, and others, will be excellent mediums on which to operate, as they are strong growers and impart a more vigorous constitution to some of the finer-flavoured but slower-growing Pears. Should any of the trees to be operated on be cordons, cut them down to within a few inches of the stock, leaving just sufficient wood above the latter that the scion may be conveniently grafted on and be just clear of the stock. Pyramids and bushes of both Apples and Pears should have the branches reduced to six or eight. Leave these about 6 inches long; they will then quickly make good heads again. Fan and horizontal trained trees may have their branches cut back to within a few inches of the stems, leaving sufficient wood to enable the grafting to be properly performed. Standards may have their heads reduced to the like number of branches recommended for bushes and pyramids, according to size and age. When these details have re-

will result. The tying or binding on of the scions is also another important matter, as they must be bound on firmly, but not to such an extent that the ligatures will cut into the bark. Broad strands of Cuba bast or raffia are the best materials to employ for this purpose. The final operation is, of course, the smearing over of the point of union with grafting wax or clay. The former is now generally used, and it saves no end of trouble. Claying, however well it may be done, will, and does, crack, and requires a deal of attention if air is to be excluded. Grafting-wax is much more portable than clay, it is more easily applied, can be bought ready for use, and has the great recommendation of being cheap.

NOTES AND REPLIES.

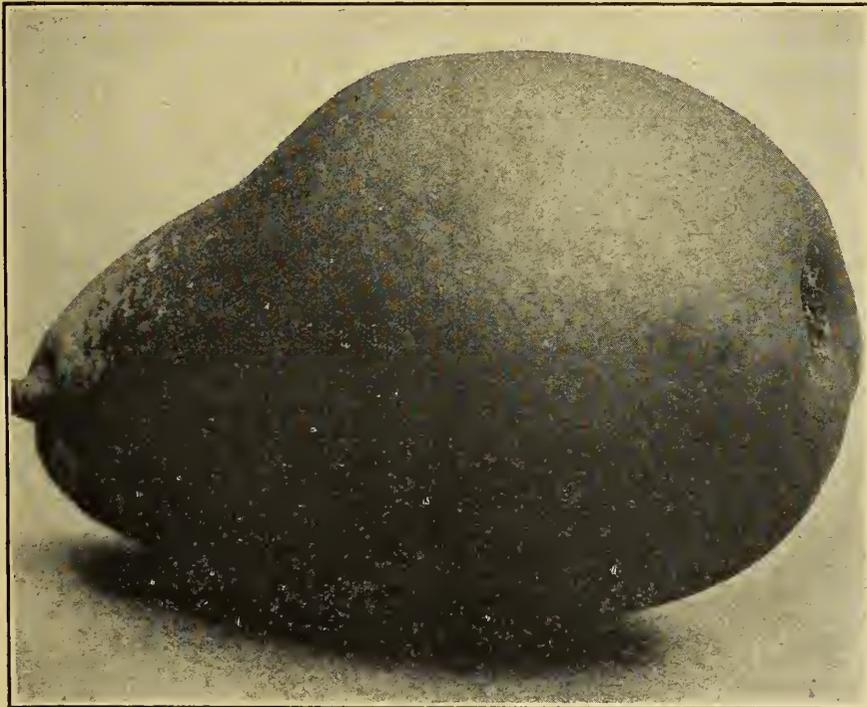

Peaches and Nectarines in cold-house.—I have some Peaches and Nectarines under glass, but no heat. They are now in full blossom, and I shall be much obliged if you will advise me as to what watering and spraying should be done from now on. Roots reach to outside.—E. A. Cox.

[Peaches under glass need constant attention from the time of flowering until the end of the season, beside watering, which is governed in its extent and frequency by the nature of the soil and the house. Some soils of an open or light character would require twice as much water as that of a heavy or clayey nature. A watering should be thorough when given, and if a covering of straw litter be spread over the surface less water will be needed. Plenty of air should be given the house while the trees are in bloom, and at about midday give each tree a gentle shake so as to disperse the pollen grains. When a good set of fruit has been obtained syringe the trees daily in bright weather through the hottest part of the spring and summer, or your trees will become infested with red-spider, one of the smallest, but the most destructive, of garden insects. You should open the ventilators in the morning before the sun affects the temperature, and close again as soon as the sun passes off the house. At closing time is when syringing is the most beneficial to the trees.]

Gooseberry Lancer.—I do not say that Lancer, an early and very large Gooseberry, is the best flavoured Gooseberry, as most growers know that if one seeks for flavour alone the smaller berried kinds, such as the Gage and others, must be relied on. Lancer is a very heavy cropper and one of the earliest and largest Gooseberries I have grown for early picking. It is a grand market variety. The berries are greenish-white, oval, smooth, and when allowed to ripen on the tree of good quality. Its true worth undoubtedly lies in its fine fruit early in the season, its heavy cropping and well-doing in most soils. It has received a first-class certificate from the Royal Horticultural Society for its cropping qualities.—K.

Fruit-trees in pots.—Growth is now active, and the pots have been plunged to half their depth in the border, which was prepared for this purpose. When this plunging can be followed, it is perhaps preferable to top-dressing the plants. In the latter case there is a reduced space for watering, whereas when plunging is resorted to, not only can ample supplies of moisture be given, but the roots may push through the bottoms of the pots in search of nourishment, while, in addition, the roots in the pots are kept cooler during the hot summer days. As these trees are not required particularly early, the house is yet fully ventilated both by day and by night, even if a few degrees of frost are anticipated.

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. Cloth, medium 8vo, 15s.; post free, 15s. 6d. Of all Booksellers or from the office of GARDENING ILLUSTRATED, 63, Lincoln's Inn Fields, London, W.C.

Pear Mme. du Puis. Gravetye, Sussex.

fruit-trees in gardens and orchards, always provided the trees to be grafted are not too old and that they are perfectly healthy. It is a sheer waste of time and labour to re-graft very old trees, the heading back seeming to paralyse them, and if the scions take and growth is made they never form good heads, and as a natural sequence fail to bear good fruit. Much has been done within the last ten years in the way of orchard renovation. Thousands of young trees of good market varieties have been planted, but yet there are numbers of old trees still standing that are only fit to be grubbed. Among the healthy ones will be found many that bear indifferent or worthless fruit, and instead of allowing these to yield year after year crops of unsaleable fruit, it is far better to head them back and graft them with a well-proved variety or one suited to the district.

Turning to garden trees, the same remarks apply with regard to the re-grafting of inferior kinds of Apples and Pears, and an opportunity will thus be provided for anyone wishing to put the double grafting

received attention, a sufficient number of scions must be cut or procured, and to keep them as dormant as possible heel them in under a north wall or hedge, or where the sun cannot reach them. When large numbers of scions are required it is not always possible to obtain a sufficiency of young wood for the purpose, but this does not matter, as the older wood may be used, provided there are dormant buds upon it. With regard to the

METHOD OF GRAFTING, that called whip grafting generally obtains in gardens. Crown and saddle grafting may also be found necessary in some cases, and for orchard trees whip and cleft grafting are unquestionably the best methods. Success in grafting does not depend so much on the method adopted as on the manner in which it is performed, and the work is always best entrusted to an experienced person, especially when a number of trees is to be grafted. There must be a perfect union of scion and stock, and to this end the scions should be so cut that they fit to a nicety, if not on both sides certainly on the one side, and if this is not done failure

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM MARCH 17TH.—The *Cornelian Cherry*, *Forsythia intermedia spectabilis*, *Cydonias* (in various colours), *Andromedas* (various), *Skimmias*, *Alnus cordifolia*, *Box* (various), *Yew*, *Berberis* (in variety), *Daphnes* (in variety), *Periwinkles* (various), *Osoberry* (*Nuttalia cerasiformis*), *Purple Plum* (*Prunus pissardi*), *Milkwort* (*Polygala Chamæbus purpurea*), *Ericas* (in great variety), *Azara microphylla*, *Arbutus canariensis*, the *Gout Willow* (*Salix caprea*), *Ribes sanguineum*, *Saxifrages* (in variety), *Scilla sibirica*, *S. taurica*, *Puschkinia scilloides*, *Crocus* (in great variety), *Hepaticas* (in various colours), the *Poppy Anemone* (*A. coronaria*), the *Greek Anemone* (*A. blanda*) (various colours), the *White Wood Anemone*, the *Scarlet Windflower*, *Violet Cross*, *Arabis*, *Aubrietias*, the *Bitter Vetch* (*Orobis vernus*), *Candytuft*, *Violets* (in variety), *Snowdrops* (in variety), *Narcissus* (several kinds), the *Corsican Hellebore*, *Lenten Roses* (in variety), *Polyanthuses*, *Grape Hyacinths*, *Chionodoxas* (in variety), *Dog's-tooth Violets*, the *Algerian Iris* (*I. stylosa*), *Netted Iris* (*I. reticulata*), *Triteleia uniflora*, *Hyacinthus azureus*, the *Great Pilewort*, *Spring Snowflakes*, *Veronica filiformis*, *Polemonium sacharatum pictum*, *Blue-eyed Mary* (*Ornithodes verna*), *Eranthis hyemalis*, *E. ciliatus*.

WORK OF THE WEEK.—The weather of the past week has been all against outside gardening, as the land is in such a sodden state. When heavy land gets into such a condition as it is in this district at the present time it is best to leave it alone until the surface water has had time to get away—at least, this applies to ground which is under cultivation. A retaining wall has been built to support a rather steep bank, which was continually slipping, and, although the first consideration is to support and keep the bank in place, we intend to plant Violets on the top, and a few other alpine plants between the sandstone blocks. A group of the *New Zealand Reed* (*Arundo conspicua*) has been cut well over, after the manner of the *Pampas Grasses*, as by this means the appearance of the plants in summer is improved and the full strength of the plant goes into the leaves and flowers. A large group of *Skimmias*, which had occupied the same spot for a number of years and were too large to transplant with safety, has been destroyed as the ground is required for more important things later on. A rough piece of land, which had been an eyesore for a long time, has been levelled ready for future planting. A *Thorn hedge* has been cut off to within 3 feet 6 inches of the ground to encourage the growth at the base. From a number of *Corsican Pines* the lower branches, which overhung the road, excluding both light and air, have been removed. A piece of ground near the waterside, occupied chiefly by *Thorns* of the *Cocks spur variety*, *Berberis*, *Cydonias*, *Viburnums*, *Purple Plum*, and various other subjects, has been cleared of undergrowth, which had become almost impregnable. A large colony of late *Daffodils* near the same spot had become congested, therefore the opportunity was taken to lift the greater part of them, split up the clumps, and transplant in long, broken lines by the sides of the walks. It is late for such work, but I have no doubt of the result. A plot of ground has been prepared near the shade of a Holly for a few plants of a large-flowered variety of the *Hungarian Hepatica*, which had recently come to hand. *Dahlias* have been put into boxes and placed in gentle heat, *Fuchsias* and *Hydrangeas* for the flower garden have been top-dressed. With the pruning of the *Winter Sweet*, *yellow Jasmine*, and *Chinese Quince*, this work has been brought to a conclusion.

Sussex. E. M.

SOUTHERN COUNTIES.

Orchards.—Another spell of wintry weather has afforded an opportunity for giving fruit-trees in orchards a look over. In regard to bush-grown trees the pruning is carried out on much the same principle as that accorded to trees grown in the garden, only a little more latitude is allowed in respect to the extension of the main branches. In the case of standards the pruning consists more of a general overhauling of the trees, such as cutting out of dead wood, thinning the heads little or much where necessary, and in thinning, regulating, and tipping the extension growths on young trees in need of such treatment. When necessary to remove branches of any size, the wounds should be dressed directly afterwards either with lead coloured paint or Stockholm tar. This keeps out wet and prevents fungus germs and resulting decay of wood. The heads of *Plums* and *Damsons* must not, if they require it, be too severely thinned, especially in districts where hullfinches and other birds which destroy fruit-hulls abound, otherwise there is just the possibility of the crop proving a very scanty one. The only way to put a stop to the depredations of these birds when they attack the trees is to shoot them. Standard *Morellos* require the same treatment as the preceding. As regards dessert *Cherries*, the season is too far advanced to do more than cut out any dead wood which may be present. Restaking and

the tying anew of young trees are other matters requiring attention, while the wire-netting used for protecting the stems from ground game should be examined to see there is no possible chance of damage being done. Where rabbits are numerous, the best way of affording protection is to affix rabbit-proof netting to the boundary fence, letting the lower edge of it into the ground some 5 inches or 6 inches in depth.

Cauliflowers.—The young plants raised from the January sowing, and which were subsequently pricked off into boxes, are now well rooted and of a size to warrant their being transferred to a frame on a bed of fermenting material, where they will be planted out in some good holding soil. Here they will be grown as cool as circumstances permit, so that when lifted and finally planted outdoors they will suffer no check. *Brussels Sprouts* are now sufficiently forward in regard to growth to allow of their being treated in a similar manner.

Chilies and Capsicums.—Where these are in request both for ornamental as well as an adjunct for home-made pickles, the present is a good time to sow seed in heat and raise the necessary number of plants.

French Beans.—To keep up a regular supply sowing should take place every ten days or twelve days. There now being greater conveniences available in the way of suitably heated houses, their forcing does not present so many difficulties as was the case earlier in the year. The great thing is to see that the plants never want for water at the roots and to keep the foliage well syringed, except, of course, when the plants are in flower. This prevents attacks of red-spider, which is the chief thing to guard against when the forcing of French Beans is conducted in fruit-houses.

Tomatoes.—Plants raised from the January sowing are being placed in their fruiting pots, 10 inches in diameter. The pots are well drained and two-thirds filled with a mixture of good fibrous loam, a little leaf-mould, and old Mushroom dung, a sprinkling of wood ashes, and a little bone-meal. The plants are put as low down in the compost as possible, and a stake used to support each until they reach the first wire of the trellis. As the method of training adopted is that of confining them to single stems, the latter being able to reach a length of 8 feet to 9 feet before the limit of the trellis is reached, the pots have been stood rim to rim in a single row on a stage close up to the front ventilators of the house. When the roots are in need of further assistance a layer of compost is then placed on the stage close up to the pots, the roots soon finding their way into it through the crock holes or outlets round the sides of the pots at the base.

Late Vines.—The starting of these will be no longer delayed, as the buds are already in an advanced stage of development. Preliminary work, such as the manuring and pricking up of the surface of the border, afterwards mulching it with horse-droppings and short litter, and soaking the soil with tepid water will follow the closing of the houses. To avoid having Grape thinning to carry out in both houses at the same time, the one will be slightly forced on in advance of the other, the most being made of sunheat in the meantime to help bring about that end. The starting of the vineries necessitates the clearing out of late batches of a miscellaneous lot of flowering plants, such as *Eupatoriums*, late-flowering *Pelargoniums*, *Schizanthus*, etc., for which accommodation has to be found elsewhere.

Chrysanthemums.—The potting of these into 60-sized pots is being proceeded with, and the plants are being placed in a cold pit, which will be kept close until they commence to form new roots.

Cyclamens.—These are getting past their best after having been in flower for nearly six months. With the exception of a few of the best, the plants have been put in another house for a time to rest before being placed in a pit outside. The space vacated by the *Cyclamens* has been filled up with late *Cinerarias*, *Lothian Stocks*, *Schizanthus*, *Pelargoniums*, the latest-flowering lot of *Primula sinensis* in variety, and a big batch of *Mignonette* in bloom. This has relieved the pressure in other directions and made room for the plants mentioned which have to be moved from late vineries for young *Cyclamens* which are now in need for a shift into 4½-inch pots, *Tomatoes*, and other things.

Bedding plants.—These have made excellent growth, and, with a view to having them as bushy and of as large a size as possible by the time they are required for the filling of the beds, *Pelargoniums* of the *Zonal*, *Ivy*, and *Scented varieties*, *Verbenas*, *Cupheas*, and *Lobelias* of the spreading type have been well stopped. With the exception of a compact-growing variety of *Lobelia*, the propagating of bedding plants has been brought to a close.

Seed sowing.—The seed of intermediate varieties of *Phlox Drummondii* will now be sown, also of *Papaver nudicaule* (*Island Poppies*) in variety, sweet-scented *Tobacco*, and *Sanders' red-flowered variety*, and *Nemesia*.

Annual Delphinium Blue Butterfly.—The plants are now ready for potting off. Small 60's are a suitable size for this purpose, as the

balls when turned out of the pots are then of a convenient size for planting about mid-May, when large groups of the plants are to be formed in the borders.

Cinerarias.—Seed of the dwarf-growing stellate-flowering kinds, such as *C. s. polyantha* or *C. s. Feltham Beauty*, should now be sown to provide plants for flowering at the end of the year. Germination is quickly effected in the moist warmth of a vinery being forced.

Primula sinensis and **P. stellata.**—As these are very useful for indoor decoration and other purposes in the depth of winter, a batch of plants of each type and in variety should be raised now for that purpose. The white, crimson, pink, mauve (or so-called blue), and the attractive variety named *The Duchess* are the most popular in both classes. A small pan sown with seed of each kind will provide an ample number of plants for early blooming. The raising should be carried out in heat, as for *Cinerarias*.

Rose and creeper pruning.—This has again been resumed after a suspension of near upon three weeks owing to bad weather. *Jessamines* and *Honeysuckles* have been thinned out in some cases, cleaned, and spurred back, and where necessary tied in afresh. *Clematises* of the *Jackmani* type have been pruned back to within a few buds of the base, and the same with *C. Flammula* and *C. paniculata*. These require to be well nourished at the roots. *Chimonanthus fragrans* has had all young wood spurred back to one or two buds with the intention of securing a good supply of flowering shoots for winter display. *Tea and Hybrid Tea Roses* on walls are being relieved of weak and useless wood, and such of the medium-sized shoots as are deemed worth keeping are spurred back. The strong or more robust wood is either tipped or partly shortened, according to circumstances. *Noisettes* had all weak wood cut away and the long shoots, which produce the flowers, tipped. *Banksian Roses*, which start so early, have suffered severely from recent frosts. The pruning in their case is a modification of the above-named methods. A. W.

MIDLAND COUNTIES.

Strawberries.—Plants carrying ripe fruit should be given plenty of air, and if the fruit is not wanted for a few days remove the plants to a cool, dry house and shade from strong sunshine. The fruit will not keep longer than a week when ripe. After the earliest fruits are picked the plants should be removed to a pit or any sheltered place. If they receive proper attention and are planted out as soon as hardened off good fruits can be obtained in September, if the weather is favourable. Later plants for succession require attention almost daily in thinning, leaving six or eight fruits on each. Place a small forked stick to support the fruits and prevent the stalks bending over. On bright days, and with drying winds, plants want looking over twice daily for water, as if once allowed to get dry they seldom recover. Give liquid manure water liberally until the fruits change colour.

Early Peaches started in December will now be stoning, and for a time no apparent progress will be made. Care must be taken to avoid a check to the growth by careless ventilation, remembering that, although the sun is getting daily more powerful, a too free admission of air causes cold draughts to circulate round the trees. The fruits should be finally thinned as soon as the seed-vessels become quite hard. If the trees have been established for some years and are in robust health, one fruit to every square foot covered by the branches and young wood constitutes a good crop. *Nectarines* may be left about 10 inches apart on the trees. The shoots will require to be tied into their places on the trellis, removing all but those actually required for next season's crop and the necessary extension of the trees. In tying or nailing the shoots give sufficient room for the free development of the young growths. Syringe the trees freely both morning and early afternoon on bright days with water heated to the same temperature as the house, and attend to the watering at the roots. From now until the fruit begins to ripen liquid manure should be afforded as often as necessary. If the borders are well drained they will require it frequently. If liquid manure cannot be obtained, an occasional dressing of an approved concentrated fruit manure should be afforded, well watering it in. Successional houses require attention in the matter of regulating and tying in the young shoots and thinning the fruits. In the late house the trees have set a good crop of fruit and disbudding is in progress, also rubbing off surplus fruits on the under side of the wood and slightly reducing those on the upper side.

Primulas and Cinerarias.—A small sowing of Chinese *Primulas* and *Cinerarias* will now be made for early flowering. The seed should be sown thinly in well drained pots or pans, which have been previously filled with finely sifted soil and well watered. The *Primula* seed should only be slightly covered with fine sand, and that of the *Cineraria* may have a sufficient quantity of the compost sifted over it through a fine sieve to just cover it. The pans should be placed in an intermediate temperature or on a mild hotbed, and covered with a sheet of glass, shading carefully, or preferably affording the pans a position where they will not be exposed to direct sunshine. Great

care must be exercised in watering Primulas both before germination and while the seedlings are small. A batch of seedlings might easily be ruined by one careless watering.

Flower beds.—It is necessary to stake many bulbous and other spring-blooming plants, or a storm of wind or even heavy rain will snap off some of the flower-stems. I find that stiff, plain fencing-wire, cut into lengths suitable for the various plants, and painted green, makes a good and inconspicuous stake for Hyacinths, Tulips, etc.

Tender shrubs.—The temporary protection afforded these during the winter on walls and in the open may now be removed.

Roses.—As recommended in a former calendar, the pruning of Roses, if not actually done, should no longer be delayed. As the pruning is completed clear away and burn all prunings. Where Tufted Pansies are used as carpeting plants for Rose beds the surface should be loosened and the plants put out that they may get well established before hot weather sets in. Some of the dwarf hardy annuals may be used for this purpose. Sweet Alyssum, Leptosiphon in variety, Phacelia campanularia, and many others being suitable.

Violets.—The propagation of Violets should begin now, either from cuttings or layers. Cuttings can be taken off, dibbled into boxes, and placed in the shade, where they will soon root. Increasing them by layers is the easier plan. There is usually plenty of rooted side growths, which can be planted direct into the nursery beds, where they may remain until

of the resulting plants will be best for planting in permanent quarters, and as the seed beds take up but little room, I consider it is good policy to adopt the system generally.

Cauliflowers.—A part of the plants wintered in cold frames will be put out on a warm border at the first opportunity. Drills will be drawn a few inches deep to afford as much shelter to the plants as possible, and twigs of Spruce placed round each plant. In the event of severe frost it may be necessary to cover the plants with flower-pots for a few nights. Those from early sowings in boxes have been placed in a sheltered position to harden off.

Onions that have been brought forward under glass must now be thoroughly hardened off prior to planting out. The site on which they are to be grown, having been deeply trenched and manured, advantage will be taken of fine days to prick it over with a fork, after scattering over the surface a good dressing of soot and wood ashes.

F. W. GALLOP.

SCOTLAND.

Vegetable garden.—Full sowings of all the various Brassicas were made, with the exception of Broccoli, which will be deferred yet awhile. Rather fuller sowings of these things were made than is customary, with a view to supplying surplus plants to the neighbouring cottagers in order that their gardens may be more fully utilised at this time. Onion sowing

state over winter, the action of the weather has reduced the surface to a fine tilth, which really requires no further working than a scuffle with a flat hoe and a run over with wooden rakes previous to sowing. It never pays to crowd Peas, the usual rule followed being to allow the height of the variety to rule the distance at which to sow the lines—that is to say, if a variety is 6 feet high, the distance between the lines ought to be no less than 6 feet, and so on. It is, perhaps, better to put the Peas apart in breaks in different positions, but this practice cannot always be followed. Early Cabbages are coming away nicely, and in the course of the week they were given a sprinkling of chemical manure, which was well hoed in. The winter has not, on the whole, been unsuited to their requirements. It has never been too cold to stunt, nor too open to unduly hurry on growth. The result is that heads will, in all probability be ready for cutting slightly in advance of the average time.

Asparagus beds.—A beginning has been made with the spring cleaning of Asparagus beds. The soil on the top is lightly worked up and well raked, while the alleys are similarly treated. From the latter any soil necessary for top-dressing can be taken. It is intended shortly to give these beds a liberal allowance of a fertiliser and a certain amount of soot. When the dressing is applied it will be well raked in. This is by way of a change from the customary manure of the farmyard.

Globe Artichokes.—The manure round the stools of the Artichokes was in the course of the week lightly forked in. If it is necessary to increase the stock offsets may be taken and replanted at this time. In some districts it may be advisable to give such offsets a start in pots in a frame for a time, but here it is quite unnecessary. These young plants may give a welcome head or two late in the season; but in any case they will bear freely during the following year if they are at all well done to.

Potatoes.—During the week the stock of Potatoes was inspected, and as growths were beginning to be prominent, some time was devoted to the picking over and cleaning of the tubers. Potatoes in this district have been abundant over the winter, and the price, considering the rise in value of other commodities, has been very reasonable.

Seed Potatoes.—At the same time the tubers intended for the main crop and late plantings were given a look over, and laid out thinly on shelves in order to induce the growth of stocky eyes. So far as possible, whole sets are used, these being from medium to small in size, but which were selected from roots which gave a good proportion of large tubers. A considerable area will be planted with King Edward VII., a Potato which always gives very excellent returns in these gardens, and of which I am a great admirer.

Hardy annuals.—If the best results are to be obtained early sowing must be done. Rarely has the soil at this time been in such fine condition for sowing these showy, if at times fleeting, things. To attain success, two things are essential in the cultivation of annuals. These are—sow thinly, and, after the seeds germinate, thin out rigorously. Dwarf annuals, when finally singled, ought to stand at least 8 inches apart, those of a taller habit correspondingly more. A wrong impression is sometimes arrived at as to the value of annuals, more especially when they are overcrowded. Naturally, the display under such circumstances is poor and brief; but no class of flowers will give such a fine display under intelligent culture as the at times despised annual.

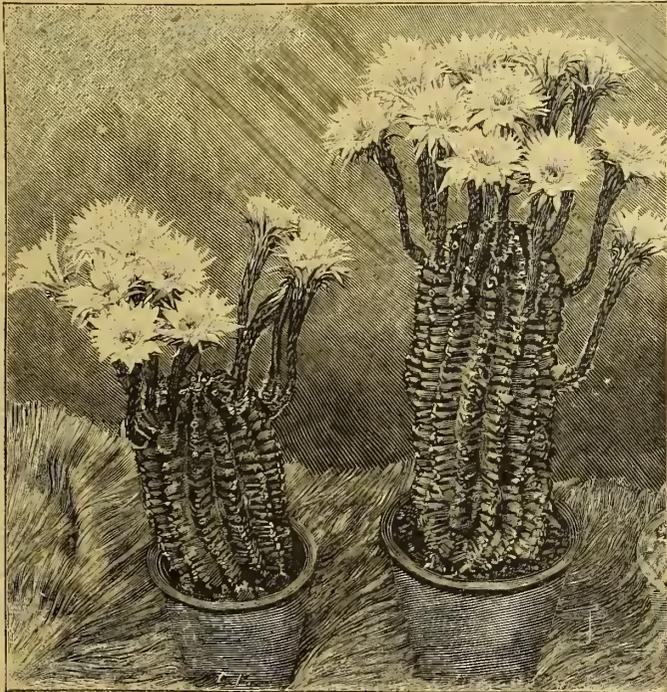

Pentstemons.—In the course of the week Pentstemons from autumn-struck cuttings, and now showing signs of growth, were removed from the heated pits in which they passed the winter, and were transferred to cold frames. For a time the sashes will be matted up at night, but as the nights get warmer the sashes will be ultimately removed. Few of the florist varieties of Pentstemons are included in this lot, the Gem varieties being considered much more useful for general work, and are in bloom throughout the summer and autumn. Opinions differ as to the advisability of pinching the shoots at this time. There is not much in it, but if pinched now the plants may be a trifle dwarfer than would otherwise be the case.

Antirrhinums.—Equally as valuable as Pentstemons, full sowings have been made during the week. Intermediate varieties of distinct colours are preferred. So much improvement has been made during late years in the case of Antirrhinums that it is no wonder they grow increasingly popular. They are much to be preferred for summer beds than the usual stereotyped Pelargonium or Calceolaria. As is the case with Pentstemons, florist varieties of Antirrhinums find little favour, although there are certainly some good colours and combinations of colour among them.

Under glass the work was during the week reduced to the barest necessary minimum. The usual attention in the way of watering and ventilation was, of course, seen to, but the important work of getting out the crops during suitable weather took precedence.

W. MCGUFFOG.

Balmac Gardens, Kirkcudbright.

Echinopsis Decaisneana.

they are required for the frames next September. Single varieties may be planted into their permanent quarters.

Erythroniums (Dog's-tooth Violets) are delightful at the present time in leaf and blossom. The usual practice is to drill the little bulbs into lines for edgings, but every garden that has Grass about it which it is not necessary to mow until summer should certainly have a large colony of these planted therein. One great advantage in planting these in the Grass is that the flowers do not get spoiled by the heavy rains, and the effect is much better than when grown in beds and borders.

The weather.—The unusual fall of snow and heavy rains experienced of late have delayed seed sowing and general cropping in most gardens, especially where the soil is of a retentive nature. It is of the utmost importance that every opportunity should now be taken advantage of to bring up all arrears as fast as the state of the ground will allow. The damage done to the ground by working on it when in a moist and soft condition can hardly be over-estimated.

Asparagus beds should be neatly raked over and a dressing of some reliable artificial manure afforded.

Broccoli, Kales, etc.—A plot of fairly rich ground should be prepared on which to sow seed of the main crop and late Broccoli, Kale, and other green vegetables for winter and spring use. I prefer to make two sowings of these, one in the first week of April, and the other a fortnight later. Everything depends upon the weather and the locality as to which

and transplanting were completed under the most favourable conditions. Autumn-sown varieties are yet extensively planted, and if well harvested their keeping qualities are almost equal to those of bulbs from plants raised in heat during spring. Another point in their favour is that they can be used at an early date, and Onions are always in request. Pricking out has been finished in the case of plants raised in heat. These were put on a bed upon a declining hotbed, where they will make speedy progress. Leek seed for the main crop was also sown. A good bed of Parsley was sown, and plants raised in heat were also put out. Parsnips were sown. A considerable area has been planted with Potatoes, and although the soil may be a little cold, the excellent condition of the ground did not appear to permit of delay. The varieties at present planted include May Queen, Midlothian Early, and Beauty of Hebron. These form a useful trio, and make a very good succession. In a general way it is too early yet in our climate to sow Turnip seed; but in the present exceptional circumstances a few drills were risked. If failure follows, the loss is not great. Broad Beans will be sown from time to time as required. These are favourites here, and more space is devoted to their cultivation than is the case in the majority of gardens. To hasten the season of French Beans from outside, sowings can be made in pots. Like the Broad Bean, French Beans transplant well, and if raised in pots now in cold frames the crop is appreciably earlier. Peas, too, require attention at intervals. The ground allotted during the present season was deeply trenched and heavily manured. Being left in a rough

CORRESPONDENCE.

Questions.—*Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly written on one side of the paper only, and addressed to the EDITOR of GARDENING, 63, Lincoln's Inn Fields, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, the name and address being added to each. As GARDENING has to be sent to press some days in advance of date, queries cannot always be replied to in the issue immediately following their receipt. We do not reply to queries by post.*

Naming plants.—*All who wish their plants to be rightly named should send fair examples of each—the stem, leaf, flower, or fruit. (Snippets of leaves and points of shoots are useless.) Not more than four plants should be sent in any one week by the same correspondent. Where more than one kind is sent they should be numbered. Of conifers the fruit should always be sent.*

Naming fruit.—*Several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. We can undertake to name only four varieties at a time.*

PLANTS AND FLOWERS.

Shifting plants (A. R.).—If a freshly-rooted cutting or seedling is shifted from a small pot into, say, a 6-inch one, the chances are against the plant thriving, the body of soil being too large for the small quantity of roots. The idea of small shifts is to get the roots to touch the sides of the pots again as soon as possible, when another small shift may be given. If this is carefully done in the growing season the check is very small.

Oleanders (Oleander).—To induce these plants to flower freely they should be encouraged to make a vigorous growth during the spring and early summer, by giving them one or two liberal shifts, using rich, loamy soil, and when well rooted giving plenty of water and weak liquid-manure. At the same time they should have a light position, with little or no shade, and free ventilation. Towards the autumn ripen the growth by full exposure to sun and air.

Moving Crocuses (G. W. Evans).—The best time to transplant Crocuses is when the foliage has been thoroughly ripened off and the corms are at rest in the summer. Many people, on the score of tidiness, cut off the foliage of Crocuses before it has decayed. This is a great mistake, as in the following year the blooms in the case of the corms which have been denuded of their foliage while still green will be poor and not so numerous as when the foliage has been allowed to decay naturally.

Treatment of frozen plants (B. B.).—The proper course to adopt would have been to syringe the plants well overhead with nearly ice-cold water as soon as they were seen to have been frozen, shading them from sun or strong light, and gradually increasing the temperature. All that can be done now is to keep the plants fairly dry at the root, with a nice genial temperature of 55 degs. to 60 degs., and a moderate amount of atmospheric moisture on all fine days. Unless severely frozen most of them will probably break again.

Fuchsias starting (E. D. Daniel).—Yes, you may cut down your Fuchsias. After having done this leave them until they have begun to grow again, when you may turn them out of the pots, shake off nearly all the old soil, and repot in a mixture of equal parts of loam and leaf-soil with a little sand. Care should be taken not to over-water, yet at the same time the soil should be kept moderately moist, while a syringing overhead two or three times a day will be of great service. They will then grow away freely, and when they have well filled the pots with roots they may be given a shift into larger-sized pots.

Plants in bloom at Christmas (Inquirer).—In a well-kept conservatory there ought to be in bloom at Christmas, Chinese Primroses, single and double flowered, also *P. obconica*, Persian Cyclamens, Cinerarias, Zonal Pelargoniums, Heaths (*Erica*) of several kinds, Epacris, Bouvardias, Abutilons, Heliotrope, late Chrysanthemums, and Salvia; also Roman and Italian Hyacinths, early Narcissi (Paper-white, N. Stella, etc.), and perhaps some pots or pans of Scillas, Snowdrops, Crocus, etc.; also Violets, Christmas Roses, Camellias, Correas, and perhaps a few Tea

Roses, Cytisus, and others. With the aid of a stove or forcing-house there ought also to be Dutch Hyacinths in plenty, with Tulips, Narcissi, Azaleas, Roses, Lily of the Valley, Epiphyllums, Linum (Reinwardtia) trigynum, Plumbago rosea, Arum Lilies, Poinsettias, Eucharis, etc.

Fuchsias, pruning (P.).—We presume your plants are in pots, and that they are underneath the stage and getting but little water. Leave them thus until early in April, when they may be pruned hard back, and after standing a few days to heal be placed in a temperature of 55 degs. Here, with an occasional overhead dewing, growth will soon move, when the supply of root moisture may be slightly increased. They may be potted on when growing strongly, taking care not to over-water until the roots have begun to run freely.

Hyacinths failing (C. Speck).—We cannot say how the disease was created, though if you have cultivated others satisfactorily in the same soil it would point to the bulbs being to some extent faulty. The example you sent was large and firm enough and of good flowering size. The reddish colour of the skin is peculiar to some varieties, others are whitish, and so on. If you observed nothing wrong at planting time after your twenty years' experience in growing these bulbs you can hardly blame the bulb-merchant, though if he is a specialist—i.e., the actual grower of the bulbs—he may throw light on the cause, and may probably meet you in the matter.

Cineraria leaves, insects in (M. B.).—Your Cineraria leaves have been attacked by the Marguerite Daisy-fly, which burrows in the leaves of these Daisies, Cinerarias, and other composite plants, and feeds on the inner surface. When many leaves are attacked in this way the plants are not only rendered unsightly, but they also suffer in health. The best way of destroying this pest is to cut off the infested leaves and burn them, or, if the attack has only just commenced, to pinch the leaves where the grubs are. Syringing with an insecticide avails little, as this would not reach the grubs, but if done at the right time it might probably prevent the flies laying their eggs.

Sweet-scented Rhododendron not flowering (G. T.).—The Hybrid or sweet-scented Rhododendron flower freely if properly managed, and the plants placed where the wood can be ripened. Your plants fail from want of this ripening. We should like to ask what condition the roots are in. There must be something wrong when the buds drop off without opening. If the roots are unhealthy or if the soil is in a bad, sour condition that may explain why the buds drop. If the plants have ever suffered from want of water when standing outside, that might account for the failure. If, on the other hand, the plants are much pot-bound, a little liquid-manure, weak and clear, during the progress of bud formation would be a help. Clean soot-water is always beneficial to this class of plants, but keep lime in all shapes and forms away from them.

Growing Lapageria alba (T. F.).—This is one of the most beautiful of greenhouse climbers. It too often bears the name of being a slow and uncertain grower compared with the red variety. We have grown the red and white forms alongside and found that the white kind grew more strongly than the red one, and also flowered, if anything, more freely. The two forms are valuable when in bloom in the autumn when other climbers have done flowering. The leaves of the white kind are more cordate in shape than those of the red, and they do not taper so gradually towards the apex, a circumstance that may help purchasers to distinguish the one from the other when both are out of bloom. A good compost for growing the Lapageria is a mixture of very rough peat and silver-sand, adding, when filling in the hole, pieces of clinker, round which the roots seem to cling freely. Care must be taken to have good drainage, as water in plenty must be given while growing. Slugs, too, are very partial to the young growths as they appear through the soil, a good plan for preserving these being to envelop them in lamp-glasses, these effectually checking their inroads.

TREES AND SHRUBS.

Forsythia viridissima (Shrub Lover).—This is different in aspect from the better-known *F. suspensa*. It is more compact, erect, and bushy, and better fitted to use as a shrub for pots in the conservatory than its near ally. A good specimen of it when in full bloom is very rich, and a relief to the monotonous series of spring-flowering bulbs, Deutzias, and such things. The flowers are golden-yellow in colour, and wreath the stiff-growing shoots. A good group or specimen of it on the outskirts of the lawn is pleasing at this season.

FRUIT.

Peach buds dropping (L. B.).—You have been keeping the house too warm when the trees were at rest, while we have strong suspicions that the border has been allowed to get very dry after the fruit was gathered last year, and it has remained so all the winter. There is no more fruitful cause of bud-dropping than dryness at the roots, this being more frequent in the case of the American varieties. Watering a dry spot so as to thoroughly moisten it is a difficult matter.

The only way to find out whether our surmise as to dryness is the cause is to examine the border, and if you find that such is the case, then thoroughly soak the border, though we may tell you that this will not save the buds from falling, as the injury has already been done. Another season keep a watchful eye on the border, and do not wait until starting-time before watering should it be necessary. Another word of advice is that whenever necessary to water always give enough to thoroughly moisten the border down to the drainage.

MISCELLANEOUS.

Top-dressing a lawn (A. H.).—A good dressing for applying to a lawn at the present time is made as follows: One half of the quantity of compost required should be loam, one quarter thoroughly decayed manure, and one quarter road-sweepings, etc. Mix all together, then pass it through a fine sieve to rid it of stones and other substances, and spread it evenly over the lawn, afterwards working it in by sweeping the surface with a birch broom, doing this first lengthwise and afterwards in the opposite direction. When finished roll thoroughly. If the lawn is mossy or weedy, rid the turf of both before spreading the compost, loosening and removing the Moss with an iron rake, and rooting out the weeds with the aid of a Daisy grubber.

NAMES OF PLANTS AND FRUITS.

Names of plants.—*R. W. J.*—1, *Adiantum tenerum*; 2, *Pteris longifolia*; 3, *Adiantum Capillus-Veneris*; 4, *Davallia canariensis*.—*E. M. A.*—1, *Centaurea ragusina*; 2, *Habrothamnus elegans*; 3, *Sparmannia africana*; 4, *Asplenium bulbiferum*.—*A. B.*—The Spring Crocus (*C. vernus*). Very possibly Messrs. Barr and Sons, King-street, Covent Garden, could supply corms.—*E. Murphy*.—1, *Solanum* sp., kindly send flowers; 2, kindly send more complete specimen; 3, *Pulmonaria officinalis*; 4, *Doodia lunulata*.—*A. V. Brickendon*.—*Cassia Fistula* (the Purging Cassia). See also note in coming issue.—*J. White, Yeovil*.—1, Lungwort (*Pulmonaria officinalis*); 2, *Libonia floribunda*; 3, *Primula floribunda*.

Names of fruits.—*Fish*.—Apples: 1, Not recognised; 2, Lewis's Incomparable; 3, Blenheim Orange; 4, Not recognised.—*A. G.*—Your Apple is Cellini Pippin, a dessert variety in use during November.

Chelsea and Holland House Shows.—At the meeting of the Council of the Royal Horticultural Society, on March 7th, the question was raised whether, in view of the urgent need for the practice of economy on the part both of individuals and corporate bodies, the Chelsea and Holland House Shows should be suspended this year. In the course of the discussion it was agreed that to suspend these exhibitions would be to deal a severe blow to the horticultural trade of the country. The members of the Council, in coming to the decision to hold the show as usual, expressed their strong conviction that it is the duty of the Council to continue to do all in its power to maintain the prosperity of the horticultural industry; for not only is it to the national interest that horticulture should not suffer more than is inevitable during the war, but, also, it is of the utmost importance that this trade should be in a position at the conclusion of peace to meet successfully the strong competition with which it is bound to be confronted. At the same time it is the intention of the Council to loyally meet the call from the Government for the exercise of economy, and steps have been taken to reduce as far as possible the demand for labour and all avoidable expenditure. — W. WILKS, Secretary.

NOTES OF THE WEEK.

Lonicera fragrantissima on a north wall has always hitherto flowered from January onwards. Scarcely a flower has appeared this season. To-day (March 16th) I see quantities. Why is this?—E. CHARLES BUXTON, *Coed Derw, Bettws-y-Coed.*

Spring flowers.—The comparatively late date at which Snowdrops bloomed is answerable for the fact that now (March 18th) these flowers, Crocuses, and Daffodils are all in bloom together. The Snowdrops are quite fit for picking still, and in the Grass below trees the combination of these three spring favourites is very striking.—W. McG., *Balmae.*

Rhododendron Silberaad has been particularly good this season. The first flowers opened in January. At first they are of a beautiful rose colour. In ten days or a fortnight the colour fades, and they become pure white. As the flowers are so very early the best plan is to pick good pieces when the buds are fully developed and put them into a pan of water. In this way they last many weeks.—E. CHARLES BUXTON, *Coed Derw, Bettws-y-Coed.*

The season and the Daffodils.—The effects of the inclement weather we have had for some time are very apparent here in the flowering of the Daffodils. To-day (March 14th) there are but few in bloom. *N. cyclamineus* is not yet in flower, and with the exception of *N. pallidus præcox* the Saragossa Daffodil is the only one in bloom in the open. My garden is fully exposed to the winds, and a cold east one which has been blowing for a considerable time has retarded many things. The Saragossa Daffodil is not large, it is true, but it is neat and of a good yellow. As one of the Ajax varieties it is specially welcome early in the open. I have often had it in bloom in February.—Ess.

Cuphea strigillosa.—Owing, I suppose, to their lack of showiness, the Cupheas, as a whole, have never appealed very strongly to the popular taste, and yet they have a beauty all their own. *C. strigillosa* is one of the more showy of the genus, and can be highly recommended as a bedding plant, its subdued red and yellow tubular flowers, borne in great profusion, producing an effect hard to obtain in any other plant. It attains a height of about 15 inches and can be readily raised from seed in spring, or by cuttings either in spring or autumn. If

spring propagation is adopted a few plants potted up at the end of the season will furnish an abundance of cuttings.—ALBION.

Veronica laudiana.—For three years I have been trying to grow *Veronica laudiana* without success. Two fine plants are now covered with buds, which look as if they will open early in April. The buds were formed about the middle of February.—E. CHARLES BUXTON, *Coed Derw, Bettws-y-Coed.*

White Glories of the Snow.—While I am especially fond of the blue *Glory of the Snow*, some of the white varieties are very chaste. Some of these have been found growing wild, but others have been raised from seeds in this country. I have here white *Chionodoxas* which were sent me by the late Max Leichtlin and seedlings from them. With me the *Chionodoxas* do not increase very rapidly, and seedlings do not always come true to colour. Max Leichtlin's white varieties were all seedlings of *C. Lucilia*. Some are pure white but others are faintly flushed with blue or blush. A proportion of these has apparently come from the pink varieties sent me by Max Leichtlin. The white varieties of *C. sardensis* and *C. gigantea* are handsome also.—Ess.

Polypodium vulgare.—A recent note by "E. M." reminds me that this Fern is one of the commonest in Kirkcudbright, and perhaps owing to that it is not quite so much appreciated as it deserves were it rarer. Every wood, burnside, and hedgerow provide suitable soil for its modest wants, and not only so, but it is found also upon the Moss-grown trunks of trees. Variations, however, are rarely found, this being rather remarkable where the Fern grows so freely. One point I have noticed in connection with *P. vulgare* is that it is impatient of removal, rarely succeeding for a year or two after transplanting. Nevertheless, it is worth attention, although it is not so popular as the *Scelopendrium*—also quite plentiful in the Stewartry.—W. McG., *Balmae, Kirkcudbright.*

Primula malacoides.—This deserves to be grown by all who need plants for rooms in winter. Last autumn a friend gave me a few plants in 3-inch pots. In October I potted these into 5-inch pots, keeping them in a house from which the frost was just excluded. Early in February some of the plants were brought into a warm sitting-room, giving them a

light position. They began to bloom, and now, at the close of March, they are a mass of flowers from 1 foot to 18 inches high and 1 foot across, and needing no support. I noticed in autumn that damp affected the foliage. To check this give abundance of air. It is unwise to sow the seed too early, early June being time enough, growing the seedlings on vigorously from the first.—J. C. F. C.

Osmanthus Delavayi.—This shrub was just coming into bloom at the end of February, when a sharp frost of 17 degs. destroyed the majority of the flowers in a single night. It is considered by many one of the best Chinese shrubs of recent introduction, but the present abnormal season has shown its weak point. The shrub itself appears quite hardy, and when the pure white, fragrant flowers, which are produced from the axils of the leaves and at the ends of the young shoots, come through safely it is very beautiful. It is quite distinct from the well-known *C. Aquifolium* group in its tiny, narrow, dark-green leaves and its stiff habit of growth.—E. M.

Scilla bifolia præcox.—I have here a considerable number of varieties of *Scilla bifolia*, and it is interesting to note the differences between the various types, both in appearance and in their time of flowering. A few years ago I was given some bulbs of *S. bifolia præcox*. I have a few clumps of other forms of *S. bifolia* which are a little earlier, and so contest its right to the name of *præcox*, but it is really an early form. It is a handsome *Scilla*, with from ten to fifteen rich blue flowers on a scape. *S. b. præcox* is said to be the parent of the handsome *S. bifolia rubra* (not to be confounded, as it often is, with *S. b. carnea*, a vastly inferior thing). The red variety is later and not quite so fine in some respects, though its colour makes it appreciated. In a low corner at the base of the rock garden *S. b. præcox* is now in fine bloom.—Ess.

Galanthus nivalis virescens.—The Green Snowdrop, as it is generally called, *Galanthus nivalis virescens*, is one of the latest of all. The outer segments are striped with green at the base, and the petals almost all green with the exception of the margins, which are white. It is not a very vigorous grower, but thrives quite well in a light loam. Its history, so far as is known, is that it was grown in the Vienna Botanic Gardens by the late Professor Fenzl, then director. The late Herr

Max Leichtlin obtained two bulbs from him and sent one to the Rev. Harpur Crewe and another to Mr. James Allen, whence its introduction to British gardens. I have grown it for a good many years and always look with pleasure to its reappearance. A curious double Green Snowdrop, more like a *Fritillaria* than a Snowdrop, grew in the garden of the late Miss Russell at Ashiestiel.—S. ARNOTT.

Christmas Roses.—I have been very interested in reading the articles in *GARDENING ILLUSTRATED* on the subject of repotting and transplanting Christmas Roses, and perhaps a little experience of mine near Manchester may interest some of your readers. I have in 6-inch and 7-inch pots Christmas Roses of the large, pure white kind, which flower splendidly every year from November to after Christmas. I repot these every three or four years. After flowering I keep them in a cold frame until May, and then partly plunge the pots in the garden border until October and give them weak liquid-manure now and again. I have one in a 4-inch pot—and this is the item which may interest you—that has not been repotted for twenty years. The plant produces from eight to twelve splendid, large, pure white flowers at the same time as the others, and never fails to do so.—HOLLIES.

Notes from Bettws-y-Cced.—The last fortnight of cold east winds and almost incessant snow storms up to March 11th, instead of retarding vegetation, seems to have had the contrary effect. About twenty years ago Mr. P. Neill Fraser, of Edinburgh, brought some bulbs of *Anemone trifoliata*. They have increased rapidly and have only once been transplanted. I never before saw them above ground before the last days of April—generally during the first week of May. To-day (March 14th) I see a number above ground with the flowers showing. I sent you a note about *Rhododendron Silberaad*. I wonder if you know it? The very bright rosy flowers fade in about a fortnight. After that, when kept in water, they become, if possible, still more beautiful—a pure white, against which the stamens are charming. *Tulipa Kauffmanniana* is in full flower. There are quantities of buds, and even flowers, on *Gaultheria trichophylla*. The end of April is the usual time. *Epigea* repens, which ought now to be in bloom, shows no signs of any flowers.—E. CHARLES BUNTON.

Saxifraga Griesbachi.—This Saxifrage is quite hardy here. Given a well-drained ledge in the rock garden, and planted in gritty soil with an admixture of limestone chippings, it goes on making fresh rosettes. This year it began blooming in January, and the flowers are still in good condition (March 23rd), and look like lasting several weeks longer. Its singular appearance makes this plant most attractive, with its nodding spikes of closely-set flowers. The stout, wiry peduncles, as well as the bract-like leaves which clothe them, are of a clear, bright rosy-pink, while the flowers at the end are almost blood-red with yellow stamens. With age the colour of the stem fades and the bracts become more leaf-like, while the stem lengthens out, eventually reaching a height of 8 inches to 9 inches. The imbricated silvery rosettes of encrusted leaves are ornamental all the year round.—F. W. G., *Lilford Gardens, Northants.*

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. FRUIT.

MULCHING NEWLY-PLANTED FRUIT TREES.

So much depends upon the start that a young fruit tree makes the first year of planting that every care should be taken to ensure free growth. In damp, sunless summers newly-planted trees get enough, and oftentimes more than enough, of moisture at the roots, but seasons are uncertain, and sometimes we get a hot, dry summer. Trees planted in the autumn, and which before winter set in have got good hold of the soil, are not so likely to suffer, but where planting was deferred until spring some means should be taken to protect the roots. With all the care that may be bestowed upon them in the way of watering, progress will never be so good, and the trees will never exhibit that thrifty vigour as when the soil around the roots is preserved in a more or less uniformly moist state. By the middle of March a good coat of litter, some 4 inches thick, should be applied, for the drying winds of early spring are apt to unduly parch the soil before watering is thought of. Watering, indeed, in the case of newly-planted trees must be considered as a necessary evil, to be avoided if possible, for if the roots can be kept cool and moist without drenching them with cold water so much the better for the trees, the health of which in a great measure depends upon the soil in which they are planted remaining at a more or less even temperature.

With a good mulch of long manure, or some such non-conducting material, there will be but little need to water until the summer arrives, and then an occasional soaking if the weather should prove exceptionally dry will ensure to the roots the necessary amount of moisture, any deficiency of which during the first year of growth will exercise a most prejudicial effect upon the future welfare of the tree. In Normandy and in other parts of the Continent, where all that relates to the Apple is regarded as of the highest interest, mulching is considered one of the most important operations connected with the planting of fruit trees. Few planters there would consider that they had carried out the work in a thorough and workmanlike manner did they omit covering the soil over the roots with a thick layer of non-conducting material. Mulching not only acts beneficially in preserving the tree against the effects of the sun's scorching rays, but it lessens labour to a considerable extent, and where the trees are set upon slightly raised mounds it must be regarded as an absolute necessity. Drought is by no means the only enemy that fresh-planted trees have to contend with, as hard frost and continued easterly winds, drying out the soil and arresting the flow of sap, exercise an equally inimical effect upon their health. In many cases where new plantations have failed to do well the cause might be traced to the effects of a hard winter. When a severe winter is succeeded by a harsh, dry, early spring, newly-planted trees are apt to get their vitality so lowered that no amount of care afterwards will restore the lost vital energy.

NOTES AND REPLIES.

Autumn Raspberries (H. B.).—Raspberry Superlative is not a true autumn-fruiting variety, and my previous note referred to its usefulness as a catch crop (say for August or early September), when cut down lower than is usually done—that is, for the summer-bearing sorts. During the last few years some new autumn-

fruiting varieties which fruit earlier have been introduced. My practice was to cut down the last year's canes of Superlative for the purpose named to within 18 inches or so of the base, and the late fruits were produced from the growths on the canes cut back. This cutting back was done in February or March, according to the season, if early or late. "H. B." will know that the usual practice is to leave the growths (last season's) 4 feet to 5 feet long for summer fruiting. The treatment in the case of the true autumn-fruiting varieties is quite the reverse. In their case the fruits are borne upon the current year's growth, and not on the canes made the previous year. The growths of last year are cut down to within a few inches of the ground and the late autumn fruits are produced on the new wood. Only allow a few canes—two to four to each stool—and give them plenty of room and food.—F. K.

Grafting.—This, where contemplated, can now be undertaken, as the sap is on the rise. If clay is intended to be used for enclosing the scions after being worked on the stocks, this must be prepared in advance. It should be well kneaded and chopped hay mixed with it while this is being done, with the object of rendering it more binding and less liable to crack and fall off as it dries. Grafting wax is, however, the more satisfactory in every respect, and should be used in preference if much grafting has to be done. The partial heading back of the stocks having already had attention, they should now be cut at the point whereon the scions are to be worked, and the wounds pared quite smooth with a sharp knife. The preparation of the stocks should immediately precede the operation of grafting. For ordinary garden purposes whip-grafting is the best method to pursue. After the perfect fitting of each scion to the stock, on one side if it cannot be done on both, it should be securely tied and then waxed or clayed over.—A. W.

Strawberries in frames.—My first experience of frame-grown Strawberries was in the north. I required a considerable quantity of fruit the last week in May and till the first fruits were ready from the open ground. I readily secured these from plants given frame protection. The plants were grown in boxes, six plants in a box. They were housed early in April and soon responded to the increased warmth. I was careful to air them, retaining as much heat as possible by closing early and covering the glass with mats on cold nights. Grown thus the plants gave fruits equal in quality to the best from the open ground. To get a catch crop to follow the forced ones I have frequently placed frames over young plants on a south border. The boxes, 6 inches deep, 2 feet long, and 12 inches in width, were home made from strong Pine boards. The plants were put into the boxes early in August. Some growers plant in frames in the late summer for this work, but I do not think this is a profitable way, as the frames cannot be used for other purposes. Much better plant good runners early on a raised south border and leave room for placing the frames in position over the plants in the spring.—M.

Vine buds not breaking (A.).—Strong young Vine rods often break irregularly—the top buds starting first. Especially is this the case if the canes are allowed to remain quite straight. They should be carefully bent round, so that the topmost buds are on a level with the lowest as nearly as possible. If this is done, and the Vines were well ripened in the autumn, but little difficulty should be experienced in the matter. Frequent syringing of the canes with soft tepid water is a great assistance in inducing the buds of Vines to break regularly when forced.

PLANTS AND FLOWERS.

INDOOR PLANTS.

COCOS AUSTRALIS.

This distinct and graceful Palm, from Paraguay, has been growing out of doors for the past six years in the south of Ireland, where it has even developed its curious long, green flower-sheaths, which occasionally open and disclose the tuft of white flowers. The sheath opens late in the autumn, and the cold which then prevails tends to minimise the extension of the flowers. Where the plant succeeds it is ornamental, but it probably demands greater damp-heat than is obtainable in the British Isles. R. H. B.

FERNS FROM SPORES.

W. McGuffog (page 101) refers to the present time as being very suitable for sowing the spores of Ferns. With this I quite agree, despite the advice that one sometimes hears to sow in the autumn.

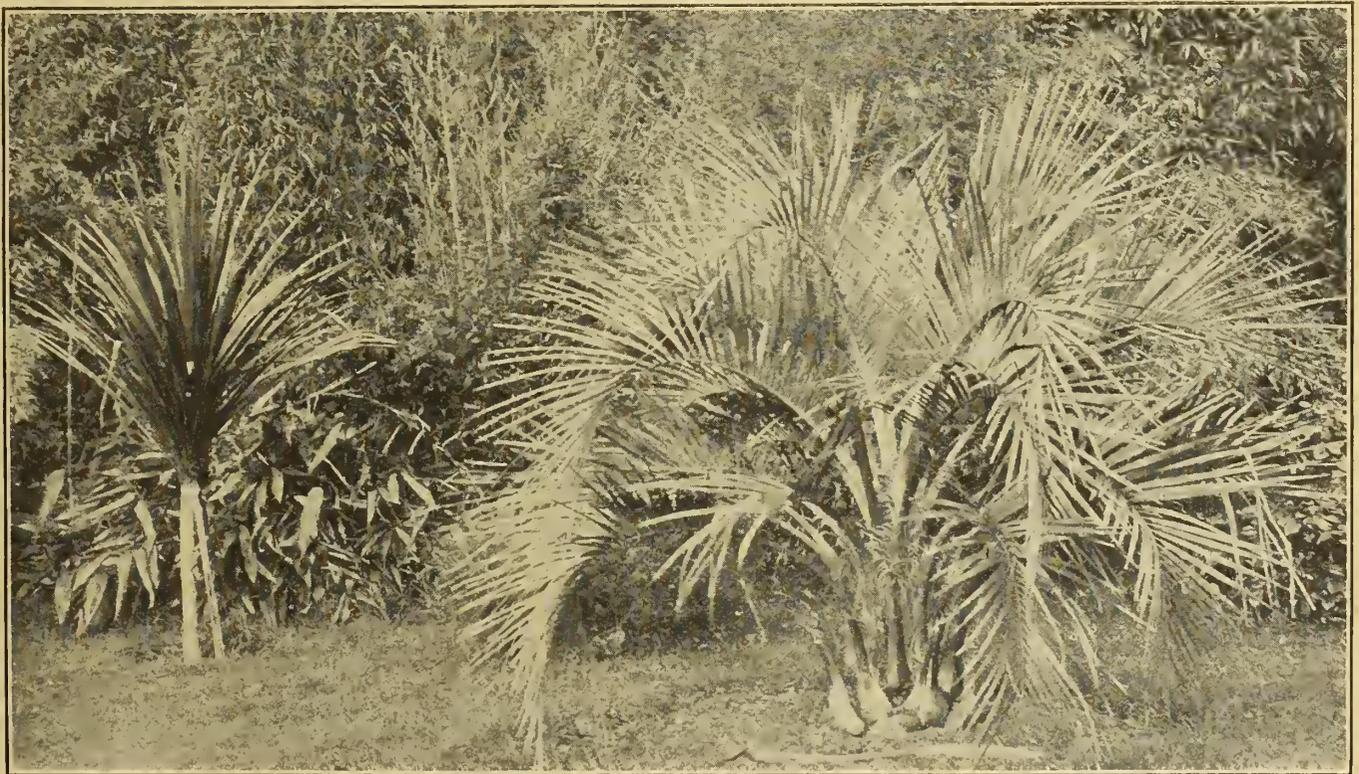

thinly on the wet surface of the soil. Then placed in a close propagating-case or with a pane of glass laid over the pot or pan they will soon germinate. In sowing, care is necessary not to get the spores mixed, for they are so minute as to float about in the air. A good plan is to stand the prepared pots at one end of the propagating-house or in a shed, taking just as many as are required for one kind to the other end of the same structure. When these are sown they should be removed to the case away from the others and the hands thoroughly wiped. In this way Ferns may be raised true to the spores sown, which is not the case if some precaution is not taken. However careful one may be, there is a tendency to sow too thickly, so that when the spores germinate there is a dense, unbroken mass of green. Decay is liable to set in then, and in order to prevent it the tiny sporlings may be pricked off. For this purpose the topmost layer of soil should be

is also wanting in the brightness of that kind. The tufted habit of *C. argyrites* readily admits of division being carried out in early spring, when the plants are started into growth. In this way a large number can be propagated from a few old plants. As far as my experience goes this *Caladium* does not flower. Though so generally known by the specific name of *argyrites*, according to the latest botanical dictum it should be *Humboldtii*.—K. R. W.

SOWING VERY SMALL SEEDS.

We are continually being reminded not to sow seeds too thickly. In the case of minute seeds, such as those of *Begonias* and *Gloxinias*, this is especially necessary, as not only are the delicate seedlings liable to perish from overcrowding, but if purchased from a trustworthy source the seeds are expensive.

For the sowing of minute seeds the pots or pans must be clean and effectually drained. A suitable compost for most sub-

Cocos australis at Ashbourne, Glounthame, Co. Cork.

The spores should be obtained by gathering a few fronds just as the spore cases commence to open. Then, placed in a piece of paper and kept in a moderately dry place the spores will soon be discharged, when they may be at once sown, although they will retain their germinating powers for some time. The soil is not of very great moment, though for general purposes a mixture of loam, peat, and sand is desirable. The pots or pans should be well drained, and I prefer the top layer of soil to be sifted fine, as this facilitates the operation of pricking off when growth takes place. Frequently a worrying little Moss makes its appearance about the same time as the Ferns, and chokes the more delicate kinds. To obviate this it is an advantage to sterilise the compost before it is used, as not only the Moss, but other pests are thereby destroyed. The prepared pots having been well watered, either through a very fine rose or by standing in a receptacle of water nearly to the rim, all is then ready for sowing the spores. They should be sprinkled very

very fine and light, so that when tiny tufts of growing spores are lifted with a pointed piece of stick they may, when placed in position, be pressed by the finger into the soil without injury. When the pot is filled, watering through a fine rose will complete the work. The pot must then be returned to the propagating-case. W. T.

Caladium argyrites.—This is one of the most distinct of all *Caladiums*, and one of the most useful. Its dwarf, tufted habit and profusion of small leaves, remarkable for their clear markings of vivid green and white, render it of great service for decoration. A drawback to the large-leaved varieties is that they are so readily injured by exposure, but *C. argyrites* is not nearly so delicate. For edging groups it is well suited, while well-balanced plants in small pots are of great service in table-decoration. There is another dwarf form—*C. minus erubescens*, with red leaves, but it does not possess the graceful character of *argyrites*, while it

jects may be made up of one part each of loam and good leaf-mould or peat to half a part of sand. The soil should be sterilised before using, in order to destroy both insects and undesirable vegetable matter. Then pass a portion of the soil through a sieve with $\frac{1}{4}$ inch mesh, but do not rub it. The rough parts should be put on one side and the fine on another. In filling the receptacles the coarse portion must be put immediately over the crocks, and then, if required, a little of the unsifted soil. It will be necessary to leave space for about $\frac{1}{2}$ inch of the finely-sifted compost, as this will facilitate pricking off later on. The soil must be pressed down moderately firm and made quite level. Before sowing the seeds the soil should be thoroughly watered. This may be done through a very fine rose, or the pots or pans should be stood in a receptacle containing water of sufficient depth to reach up nearly to the rim of the pot or pan. The water will then enter through the hole at the bottom and percolate through the whole of the soil, thoroughly wetting it without disturb-

ing the surface in any way. This is a very safe system to follow in watering the soil after the seeds have been sown, as, if a rose is employed, unless great care is taken, the small seeds are sometimes liable to be washed together. The sowing needs, in the case of minute seeds, to be very carefully done. Some cultivators prefer to mix a little very fine and dry silver sand with the seeds in order to prevent crowding, while others sow them without this mixture. I prefer the latter method, but in the case of those who have not had much experience it is safer to use the dry sand. Sprinkled on while the surface is still wet, the seeds will adhere thereto, and in the case of very small seeds no covering will be necessary. A good plan is to lay a pane of glass over each pot or pan, a uniform state of moisture being thus ensured. A sheet of brown paper may be laid over the glass till germination takes place, when it must be removed. On no account, however, must the sun be allowed to shine on the glass, even for a few minutes, as the tiny seedlings will be quickly roasted. Newspapers may be used for shading after the removal of the brown paper. In a fairly warm, moist, and shaded structure the young plants will make progress, and before long be ready for pricking off into pans or boxes. For the carrying out of this operation the receptacles should be prepared as for the sowing of seeds. The fine soil on the surface then allows of the tiny plants being dibbled therein, while the coarser portion below will be readily penetrated by the tender roots. W. T.

Habrothamnus elegans.—Considering the number of inquiries there are for plants to cover the back walls of greenhouses, it is surprising that a plant so suitable as the *Habrothamnus* receives no attention. If grown in a pot or planted out it does equally well, and furnishes during the duldest days of winter a profusion of its coral-coloured flowers, which are extremely useful for cutting. It may be planted to cover the back walls of vinerias with perfect success, as the shade from the Vines does not appear to interfere with the wood ripening sufficiently to prevent the plants blooming at the appointed time. Unless required to extend, the plants may be cut back after flowering to within a few inches of the previous year's breaks, when the shoots made will bloom almost their entire length. The terminal flowers will open first on a shoot, then the side shoots next towards the base, and so on. The *Habrothamnus* will do in any good soil such as is used for potting, but prefers rather a strong loam. Frequent applications of the syringe to keep down red spider will be necessary.

Under glass.—Stove heat may now be maintained round about 65 degs., while other plant-houses may be correspondingly lower. With the advance of the season more time is required for watering, and in all cases ventilation requires to be carefully attended to now.

Primula obconica grandiflora for cutting.—Despite the fact that some people are affected by handling this, there can be no doubt as to its usefulness when cut. Few things are so enduring, especially in the dull winter months. I have a nice batch of plants in a house from which the frost is just excluded, and here they have bloomed continuously. A few spikes which have been cut three weeks are still fresh. The stems have been shortened twice. The giant forms are much the best for tall glasses, many having stems 18 inches long.—J. C. F. C.

The Swan River Daisy (Brachycome iberidifolia).—A good sowing of this was made in the course of the week. Many find this fine blue-flowering plant succeed when the seed is sown in the open. Here, however, it is sown in heat, and afterwards pricked off for a time into a bed in a cold frame.—W. McGuffog, Kirkcudbright.

GARDEN FOOD.

NOTES AND REPLIES.

The D'Arcy Apple.—I am amused at Mr. Strudwick's remark in *Gardeners' Chronicle* of February 26th (p. 119) about this Apple not being in favour owing to its dull appearance. Let us not add the word "Spice" to the Apple. It has no meaning, and if it had, one name is best, and that the name of its place of origin. I was pleased to hear of its tree bearing in Norfolk, as I so often heard the contrary from nurserymen. I doubt if they have tried the Apple fairly. Few nurseries have room to allow trees to mature.—W.

Potato Langworthy.—This Potato deserves all the praise bestowed upon it (page 110), for although of quite medium size—which is rather against it for baking—it is floury when cooked and of fine flavour, qualities lacking in many of the larger varieties this season. Cooked in their skins and peeled just before serving, the excellent flavour is retained. This method of using them I much prefer to the common practice of mashing all into a pulp. It is a very good cropper, too, the tubers fairly plentiful, if not so large as those of many others.—E. M., *Sussex*.

Rhubarb Hawke's Champagne.—This is worth extended cultivation on account of its superiority over older kinds, and is specially valuable for preserving. For early forcing it is one of the best, being only a little behind what may be termed the first earlies. The stalks are red all through, so that when cooked it preserves its bright pink colour, and is of a brisk flavour. This variety is one of the best for the open ground, as, being a late grower, it may be had in season for a long time, and does not run to seed so much as the early varieties. It is of vigorous growth, and the stalks are very solid and heavy.

Potato King Edward VII.—Last season I formed a high opinion of King Edward VII., which was all that could be desired from an eating and cropping point of view, and highly valued for baking. This season this variety, grown on adjoining ground from the same seed, is not worth baking or boiling. In this district, after a rather long spell of hot weather, rain fell incessantly for three or four days, this being followed by a considerable drop in temperature, especially at night, after which the foliage disappeared as if by magic, filling the air with its unpleasant odour. Although the stored tubers have kept remarkably well, my opinion is that they were more or less diseased.—E. M., *Sussex*.

Quality in new sorts of Potatoes.—Quality in some sorts of Potatoes improves by cultivation. One of the most striking instances has just come to my notice in Evergood. Needing a supply I asked a greengrocer to send me a couple of sorts. He sent Evergood and King Edward. I was surprised to find the former nealy, of good quality, and equal to King Edward. When Evergood was first sent out I grew it on a heavy soil. The crop was enormous, but no one would eat it, and I discontinued growing it. Now, after a dozen years, I am pleased to find it so good. Growers tell me the crop is much smaller than when first sent out. I have found the same thing with most new kinds. Magnum Bonum now seems to have almost gone out of cultivation. Unfortunately the vigour that is in these seedlings causes them to be so productive, but as time goes on the tubers are firmer and the quality improves.

When the American kinds were first sent out they were close, and I always found them more suited for dry, sandy soils.—W. SURREY.

Celery (green) for stewing, etc.—Many are under the impression that Celery has no value unless it is blanched, but this is a mistake. This season I had a long row which did not get earthed up. At the close of the year it occurred to me that this would make good food if stewed. I lifted a portion, trimming off the roots and the ends of the green leaves and any rotted portions. The remainder was boiled in clear water with a little salt, using as little water as possible. This made a delicious dish. Some time ago I told a lady friend about this way of using unblanched Celery, and after trying it she told me it surpassed Seakale. Many people think that Celery is not hardy and must be earthed up. When green, few things are more hardy. If the stems are large and soft they suffer by bursting from frost. Green Celery I also find useful for flavouring. When that in trenches is over nothing is so serviceable as some plants to take leaves from.—WEST SURREY.

Sorrel.—Having grown most of the Sorrels I have not found one superior to the large De Belleville, so much grown for the Paris markets, and introduced some years ago by the Messrs. Vilmorin. Sorrel is not what one would term an every-day vegetable, but in the spring it is excellent for salads, as the young growths are produced at a season of the year when there is a limited supply of material. There is no gain in sowing too early. For years, having selected a good variety, I found it advantageous to divide just before the new growth started. This done, I usually had plenty of cutting material, as the plants soon respond if planted in good land. For cooking, a large-leaved variety such as De Belleville is a great gain. A plantation from divided roots lasts three years, and will give good cutting material for the time named. By lifting a number of roots and placing in cold frames on just a little warmth a much earlier supply is obtained. There are other good varieties, such as the Broad-leaved French and the Green Mountain, but the one noted above is one of the best, as it does not run to seed quickly. In all cases it is important to have the leaves quite fresh.—F. K.

Celeriac Paris Ameliore.—This is an excellent sort, the root solid, shapely, and of the best quality. I am aware it does not approach the well-known Giant Prague, the one so much grown (also at one time largely imported from Germany), as regards size, but the French variety is ideal for the private garden, and owing to its compact growth can be grown with less trouble, and is readily prepared for table. We do not make sufficient use of the Celeriac as a winter vegetable, as it can be grown with little trouble and at small cost. Many growers advise sowing in a pan or box in heat, like Celery, but if sown too thickly, allowed to remain too long in the seed-pan, or given too much warmth, the seedlings get much weakened. My best plants were always obtained from thin sowings in April in cold frames, planting out before the seedlings got at all large. This done, there was no check. Though some may think this would mean late planting, such is not the case, as there is a saving of labour and ample time for the plants to make their growth if sown early in April.—F. K.

Bottling Tomatoes.—I shall be glad if any reader can tell me the best way to bottle Tomatoes for winter use?—L. C. D.

OUTDOOR PLANTS.

PLANTS IN WATER GARDENS.

THE illustration shows the beauty one can have by the waterside, which in our country occurs so often. The number of plants that can now be grown in or near water is very great, many of them plants of extreme grace even when out of flower. Many of them, too, require very little attention, and give a far prettier result than the old arrangements used to give. It would not be an exaggeration to say that there are many places in every county where such advantages from water occur that are never seized as they have been in the case of this garden.

HARDY FLOWER NOTES.

MYOSOTIS DISSITIFLORA.—G. Algar Temple's note on this Forget-me-not (p. 93) affords one more instance of the

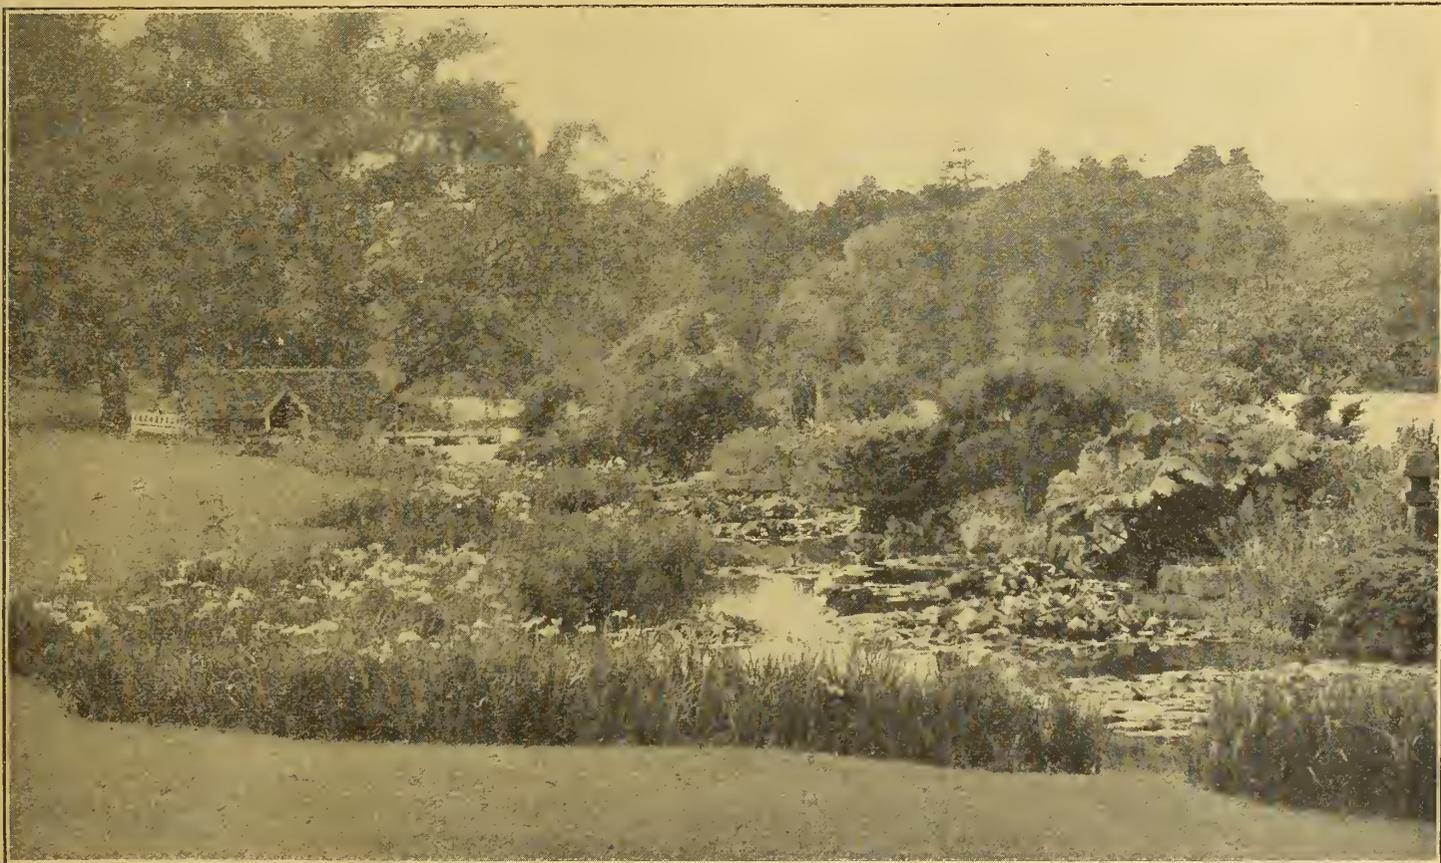

influence the productive powers of some things.

CHRISTMAS ROSES.—I am engaged in a struggle with these, but fear that I may be worsted. I have been growing them for many years past, have raised thousands of seedlings, not only from the old niger, but also from major, maximus, altifolius, Mme. Foucade, and others. I cannot say that the culture of Christmas Roses has been quite a labour of love with me. My soil is not bad for them, but I am not so well furnished with natural shade as I could wish, and as I wanted to grow them by the hundred the greater portion of the stock has had to be in open positions. Artificial shade and shelter are not like those afforded by a superior vegetation, and a certain amount of watering is needed, without which there can be no flowers worth speaking of. By attending to these cultural details I obtained

plant on fresh ground, but some of my plants are ten years old and I do not want to lose them.

NARCISSUS NANUS is now (February 16th) blooming freely in sheltered positions. Those who do not possess this little Daffodil should make note of it for autumn planting. It is so early and so easy to grow.

CAMASSIA LEICHTLINI.—I am pleased to be reminded of this species. Not having seen it for some years I had forgotten it, and I am not acquainted with the newer forms mentioned by Mr. Arnott, and which, being improvements in colour, should certainly be worth growing. Although this species has not the quaint beauty and nobility of aspect of its relative, Cusicki, it only needed the improvement in colour to make it a really good garden plant, and worthy of extensive culture. It is one of those things that would

Water garden at Buckhurst Park, Sussex.

varying influence of soil or climate on hardy plants, and of how impossible it is to lay down any hard and fast rules with respect to their culture. I do not know Cornwall, but it is a fact that many things that flourish there will not take on perennial vigour here in Surrey, and some would be killed in a winter above the average in severity. It may be that spring frosts, which are apt to cause much damage here, affect the seeding powers of this species, but I am inclined to the belief that it is a matter of soil or climate, or perhaps both. Anyway, it is with me as I have stated. Some things display considerable eccentricity in this way, as, for instance, Daffodils. My soil suits these, but only the Tenby and Emperor bear seeds, and, strange to say, they do so abundantly. Horsfield and Sir Watkin, which maintain their blooming powers for years when not lifted, have never produced a seed, which shows how curiously and unaccountably soil and climate

really good flowering plants, and could annually cut thousands of blooms. The disease which in some places plays havoc with this plant has, however, put an end to this happy state of affairs. It came on in earnest some five years ago, and for the past two years I have had scarcely any blooms. The plants start into growth freely enough, and look well until about the middle of August, when they gradually decay, and by October there is scarcely a bit of green left. I am now trying syringing with sulphide of potassium twice in the season—early in June and a month later. I also thoroughly dressed the surface soil and crowns with fresh lime. I shall do so again this year, and if a cure more or less complete is not effected I shall do away with them. Should I have any success I will report the result, for I know that in late years this disease has been very destructive. Perhaps the best way would be to burn the plants, also the surface soil, procure fresh stock, and

best display its value when planted in groups.

DAY LILIES IN THE GRASS.—I am transplanting some roots of these, which, by long residence in one spot, have become too crowded, for although the *Hemerocallis* are very accommodating, and will remain in a fairly good flowering condition much longer than most things without division, there comes a time when they give more leaves than flowers and division of the crowns is necessary. When I have set out what I need for stock I shall plant some in the Grass, and as they are big clumps, with twenty or more crowns, I fancy they will hold their own. Many of the disappointments experienced in establishing things in the wild garden are due to the employment of small plants. Only big clumps have any chance to live and thrive.
J. CORNHILL.

Phacelia campanularia.—If readers are on the lookout for a really good blue-

flowered annual let them try *Phacelia campanularia*. I had a nice patch of it last year. It only grows about 9 inches high, but the plants are covered with blue flowers from June to September. It is useful in any dry, sunny border, or may be sown broadcast in the rock garden. Sow in April, and when the plants come up, thin out freely, for if they are crowded they will grow spindly and will only bloom for a month. The best results are obtained when the plants are sown where they are to bloom, but they may also be transplanted if care is taken.—E. T. ELLIS, *Westwood, Ecclesall, Sheffield.*

NOTES FROM LONGFORD.

CROCUSES.—I now, owing to the war, do all the flower garden work myself, and see that there are hosts of Crocuses in the two-leaf stage, so next year I hope there will be a still larger crop. Then the year following ought to see this garden really well stocked with Dutch Crocuses. The newer kinds of these are lovely and an immense improvement on the old ones. Maximilian, Margot, and purpureus grandiflorus, growing in thick clumps, each about 2 feet across, and touching each other, make a glorious show in one bed. The two former are china-blue and lilac; the latter, of course, royal purple, or rather, democratic purple, since I believe the true purple of Coronation robes is on the red rather than the blue side. This being a comparatively new garden I have as yet very few *Crocus* species, since one must lay foundations before proceeding to refinements, but red marl evidently suits this family, for the few groups of such as *C. Tommasinianns* are increasing both by seed and offsets in a very gratifying way.

On the whole I agree with the correspondent who prefers his Crocuses neat, and not diluted with under-planting. Besides slugs, there is a loss of the delight of their upspring from the ground, the exquisite vase form of the taller ones, and the shading up from semi-transparent pallor to fuller colour above. If they must be on a carpet, *Frankenia laevis* makes a pretty one, while the tiny pale pink flowers it bears later on are rather fascinating. One also gets a good purple and gold effect from the gold variegated *Aubrietia*, which is flowering early this year, and out of which stand some rich lilac Crocuses, a few shades darker than the *Aubrietia* blossoms.

MEGASEA STRACHEYI.—"E. M." speaks of this as being among the hardy ones, but here I find each year for three seasons past its flowers have been quite spoilt by cold, turning brown before more than a very few of them had expanded. I put a hand-light over it this spring, but even that did not give satisfaction. It was planted for some time in a sheltered but not over sunny spot close to a Holly hedge, where *Hepaticas*, some *Primulas*, *Lilies*, and *Hellebores* do well; but has now been transferred to a south border under a wall to see if that will suit it any better. *Megasea* are extremely easy to raise from seed, but in my experience very slow to flower. A large batch I planted on a bank in my old garden was still there when I left, sizeable, but unbloomed, after at least four years of existence. I have just divided a box full of seedlings from last year's sowing with various friends, after setting many in divers parts of the garden, and hope I may live long enough to see some of them blossom. They appear quite indifferent to situation, for all, in sun or shade, rich soil or poor, are equally advanced in growth.

CLEMATISES.—Is there any advantage in

layering Clematisses to get them on their own roots? If not I do not see why it need be done, for it is a troublesome operation, slow, and there are so many risks for the layers, usually of necessity in an awkward position. Cuttings of the young shoots, taken with a bit of the wood from which they spring in March, strike quite easily. I do not even trouble to put them into a propagating case, or even a box with glass over it, but merely stick them into pots of, sandy soil and stand these on the greenhouse stage over the moderate heat of pipes that keep the place up to about 60 degs. as a maximum. They must be syringed daily. I should be most grateful if anybody would tell me the name of a Clematis I once had and cannot now identify. It was in all ways ideal for an arch, of Jackmani type, but a very compact grower, extremely free flowering, and possessing that special charm some few have of young flowers opening either paler or deeper in shade than the older ones. Its colour was a rich, lilac-purple, not nearly so blue in tone as the type Jackmani, while the flowers were a trifle smaller. No bar or marking; dense masses of rich rosy-plum-purple flowers in two shades, completely covering the top of an arch, and lasting a very long time. In those days I did not know about cuttings, and tried to layer it without success owing to a very bad season. I now wish to plant it here, but although I have sent for all I could find that seemed to answer the description it has not turned up.

PRIMULA WINTERI.—How is it that this, one of the loveliest plants ever shown, does not get into commerce? I have been looking in vain to see it offered in catalogues. Is it difficult or what? Some of these new *Primulas* are, I should think, very disappointing to the amateur grower, and some of them have curious ways. Last summer I had a box full of fine, healthy-looking seedlings of *P. Littoniana*, some with leaves 3 inches long, others smaller. In early October, thinking them too crowded in the seed-box to remain in it all winter, and, of course, fearing to trust them to the mercies of our wet west-country winter outside, I pricked them off into small pots and placed these in the greenhouse—heat not exceeding 55 degs. at any time. Instantly they all lay down and apparently died. I nevertheless hoped, and having been kept just moist, and in the same situation ever since, they are now (March 17th) each putting up a minute pair of leaves scarcely bigger than the original seed-leaves. M. L. W.

HOME SEED SAVING.

THE opening of Polyanthus buds reminds one of the advisability of picking out the best of these, and many hardy and half-hardy annuals, as the flowers appear, for the purpose of seed saving, for it seems likely, if the majority of growers are to have a display in the garden, they will have to depend mainly on hardy flowers and annuals, and if the best blooms from various standpoints are picked out and seed saved from them there is a decided chance of still better results. The favourite colours in Polyanthuses are white, clear golden-yellow, and a rich maroon, and if to the colour are added depth, length, and strength of stem, size of fruss, and thick, fleshy foliage, one is fairly sure of a satisfactory batch of seedlings. One of the earliest summer annuals is the *Corulfower*, and here again considerable improvement can be made by careful selection alike in size and colour of flower, also a somewhat dwarfer, sturdier race can be perpetuated that would be useful for

small borders, as for a similar purpose a race of dwarf, very free *Nasturtiums* can be acquired. The very free seeding of things like *Antirrhinums*, *Pentstemons*, and *Starworts* is well known; also the fact that quite a plenitude of good things is obtainable from a batch of seedlings, so that it is rather a difficult matter to know which to save and which to discard.

The above families, too, possess the merit of growing and flowering satisfactorily at a minimum of trouble and expense.

Another interesting class of plants on which to experiment with home seed saving is the Tufted Pansies, if one wants to cover bare spaces of ground between taller things easily and cheaply. *Pencailand* is a good white to save from, as although not one of the largest flowers, it combines purity with quite an agreeable perfume. *Klondyke* (yellow) and *Councillor Waters* (crimson-purple) are very good. Among the flowers much appreciated for cut bloom, single *Pyrethrums* take a prominent place, and it is well to have a few seedlings on hand in white, pink, and scarlet. E. B. S.

Hardwick.

NOTES AND REPLIES.

Polemonium Richardsoni.—This forms a neat clump 1½ feet to 2 feet high, and produces a wealth of beautiful light blue flowers, which are very suitable for cutting. Last year I sent a lot of flowers to the military hospitals, and heard that they lasted a considerable time in water. The plant blooms for a long period. In my garden last year it started blooming during the first week in June, and continued to flower till August. It should be placed near the front of the border and needs very little staking. Plant now, letting the site be well manured. It will thrive in light shade. In the summer cut the flowers regularly, for it is only by doing this that the plants keep on blooming.—E. T. ELLIS, *Westwood, Ecclesall, Sheffield.*

Grass smothering Ivy (*Cornelius B. Fox*).—You may in time, by persistently pulling out the Grass as it shows through the Ivy, be able to check its growth, but if it has got a good hold this is doubtful. The only way is to dig up the whole of the Ivy and thoroughly trench the ground, removing as the work proceeds every bit of Grass you can find. Then, we think, you may, with some hope of success, replant the Ivy.

Leaf-mould.—In your note on leaf-mould in your issue of March 4, page 130, I note you advocate the mixing of lime with the leaves. I entirely disagree with this. Lime should always be kept separate as it frees ammonia from all manures, which is lost in consequence. Nor do I consider Oak leaves as best of all for leaf-mould. They contain tannin, which retards growth. All leaves have to be collected together, naturally, when gathering up such refuse, but I think it will be found that leaf-mould composed of any but that of the Oak family is best. I have found that soil thrown among or on top of the leaves hastens decomposition.—W. C. PAED, *Jersey.*

Crocus Tommasinianus Bowles's White.—Among the numerous varieties of the pretty *Crocus Tommasinianus* raised or selected by Mr. E. A. Bowles is a charming pure white variety, which has been nicely in flower with me for some time. It is smaller than some of the other forms of *C. Tommasinianus*, but is an exquisite companion to the darker varieties, such as *azureus*, *purpureus*, and *lilacinus*. Mr. Bowles has, in addition to others, secured a handsome deep purple one, which has also been in bloom here and is much deeper than the ordinary *purpureus* sold by the dealers.—S. ARNOTT.

Crocus biflorus Weldeni Sulphur variety.—Mr. Bowles has raised an exquisite variety of *Crocus biflorus Weldeni* which I have in flower at present. The exterior of the flower is a pretty lilac, but the great charm of the flower lies in the interior of the segments, which is of a charming sulphur, much prettier than the mere term of "sulphur" would indicate.—S. ARNOTT.

TREES AND SHRUBS.

FLOWERING DOGWOOD (CORNUS FLORIDA) OF NORTH AMERICA.

This is the name which is in use in America for the Dogwood that makes such a splendid show of bloom in the Eastern States. It is quite a hardy plant and was introduced to us many years ago, but in some way it has never come into the place it deserves. It may be that it misses the splendid sun of Eastern America. I was afraid to plant it, seeing how seldom it is seen in a good state, but having tried a few of it I have been rewarded by its beautiful leaves in the autumn, and even the flowers of the red form, but I am not sure that this form is not a distorted variety in some respects, though a beautiful thing. In our country

The Red-flowering Dogwood (Cornus florida rubra).

a sunny position and sandy soil will suit it best, with a full southern exposure.

Attractive as the plant is, one much more beautiful and stately is Nuttall's Dogwood (*Cornus Nuttalli*), which abounds in some parts of the north-western coast of America, where it attains to the stature of a forest tree. It is quite hardy and fit to take its place among our choicest trees. It has also flowered with me in Sussex. The only trouble is to get a stock of it, but our nurserymen ought to be able to secure this. A certain elevation, as at Grayswood and with me, may get it out of the winter frost, and there must be many situations which enjoy this advantage.

W.

Soil and manure for Rhododendrons (G. S.).—The best soil for Rhododendrons is peat, but the common varieties will do very well in a compost consisting of leaf-mould, decayed vegetable matter, and chopped turf, with a little cow-manure for a top-dressing after planting. Of course, there are some soils not peaty in which Rhododendrons grow very

freely. It is not difficult to make up a soil in which they will grow freely where there is no excess of lime in the natural soil of the place. They will generally grow freely in woods, where the surface soil is full of vegetable matter from the decay of leaves, etc. They are also quite at home on the banks of ponds and lakes, where the soil is of an alluvial character. They must have shelter from keen, cutting winds, and moisture must be given in dry summers.

SOME NEW TREES AND SHRUBS FOR MILD DISTRICTS.

EVERGREEN HONEYSUCKLES.—One of the most charming of recently introduced evergreen shrubs is *Lonicera nitida*, which is lovely as a lawn shrub, of unique value for making low hedges, and may be trimmed and used in the manner of Box for edging garden paths and flower beds. It grows 3 feet to 6 feet high, and has innumerable rigid, twiggly, ascending, and spreading branches densely furnished with small glossy green leaves; the flowers are

toothed leaves. Both are large growing, sparsely branched shrubs with white, fragrant flowers, and relatively large scarlet fruits. Very distinct, too, is *I. yunnanensis*, with its compact columnar habit, small, rounded, spineless leaves, and pink, fragrant flowers, which are followed by small red fruits. Another good Holly is *I. corallina*, with oblong, lance-shaped leaves 2 inches or 3 inches long, undulate along the margins and sessile clusters of small, vivid scarlet fruits. This grows 6 feet to 12 feet high, with slender spreading and more or less pendent branches.

CHINESE BARBERIES.—From China, which is the headquarters of the Berberis family, there has been recently introduced a large number of new species, and among them several of quite exceptional merit. In the front rank of these is *B. Gagnepaini*, with masses of clear yellow flowers followed by black fruits. This is a compact shrub, 5 feet to 8 feet high, columnar in outline, with narrow-pointed, dull green persistent leaves. Other valuable species are *B. laevis*, *B. Juliana*, and *B. Sargentiana*, which differ one from another in size and shape of leaves and fruits, but agree in being much-branched, upright-growing shrubs, 5 feet to 8 feet high, with thick, dark evergreen leaves, yellow flowers, and black fruits. The sparingly-branched *B. Veitchi* (known in gardens as *B. acuminata*) is very distinct, and so is *B. triacanthophora*, a twiggy shrub, 3 feet to 5 feet high, and as much broad, with yellow flowers stained with red and black fruits. For rockeries and rocky places the semi-prostrate *B. candidula* and *B. verruculosa*, with small, evergreen, Holly-like leaves, lustrous above and white beneath, are most delightful plants.

WHITE AND PINK BUDDLEIAS.—For the Pacific slope two species which produce their flowers in January and February are strongly recommended. One of these (*B. asiatica*) has pure white, deliciously-scented flowers arranged on long, slender, cylindrical tails, grey Willow-like leaves, and slender arching and spreading branches. The other (*B. officinalis*) is a more sturdy shrub with broader leaves, stouter branches and broader branching heads of rose-pink flowers each with an orange eye.

SEMI-EVERGREEN BRAMBLES.—Among semi-evergreen species with attractive foliage and pleasing habit I may mention *Rubus chroosepalus*, with leaves like those of *Tilia petiolaris*; *R. bambusarum*, with tripartite leaves, dark green above and dun-coloured below; the closely allied *R. Henryi*, with lobed leaves; *R. flagelliflorus*, with entire leaves marbled with metallic green and brownish-purple above; *R. Swinhoi*, with narrow, oblong, pointed leaves, grey on the underside; and *R. ichangensis*, with vivid green, nearly heart-shaped, pointed leaves and large, elongated clusters of bright red fruits. All these Brambles have slender whip-like shoots, and when trained to poles or to a pergola are very attractive.

DEUTZIAS.—China has given us quite recently a number of, very distinct and lovely species, such as the rosy-lilac flowered *D. longifolia* and its more deeply-coloured variety, *D. Veitchi*; *D. Wilsoni*, with glistening white flowers larger than those of any of its allies; *D. discolor*, with large masses of white flowers; *D. Schneideriana* and its variety *laxiflora*, with pyramidal trusses of white flowers, and the curious *D. mollis*, with soft, hairy leaves and flattened heads of small white flowers.

CORYLOPSIS.—From China this genus has recently been considerably augmented, and such species as *C. sinensis*, *C. Veitchiana*,

yellowish-white, small but very fragrant, and the fruits are bluish-purple. This shrub roots readily from cuttings and grows freely and rapidly in any ordinary garden soil. Akin to the preceding is *L. pileata*, which has similar flowers and fruits but larger leaves, not shining, and low spreading and prostrate in habit.

HOLLIES.—China is very rich in species of Holly and a number of valuable and distinct kinds have been added to our gardens. The best of its class is *Ilex Pernyi*, a shrub 6 feet to 18 feet high, narrow pyramidal in outline, with rigid branches and small, very spinous, dark-green leaves and red fruits. Either for specimens or for hedges this Holly is invaluable. Closely allied to the above is *I. Veitchi*, which is similar in habit but has very much larger leaves. Quite unlike one's conception of a Holly are *I. Fargesii* and *I. Franchetiana*, with their long, narrow, Willow-like entire or slightly

C. Willmottiana, and *C. platypetala* are decided acquisitions. Like the Japanese species, they are spring-flowering shrubs and have pendent, short racemes of yellow, fragrant flowers, which are produced in great profusion before the leaves unfold. The leaves are grey-green, and either in flower or foliage these shrubs are of pleasing appearance. Another new spring-flowering shrub is *Stachyurus chinensis*, with pendulous racemes of yellow, scented flowers. This forms a bush 5 feet to 8 feet high, and has spreading branches, deep-green leaves, and purplish-brown shoots.

WILLOWS.—Lastly, I may mention *Salix Bockii* and *S. magnifica*, two most extraordinary Willows. The former is an upright-growing, much-branched, twiggy shrub with small grey-green leaves, and is worth growing as an autumn flowering plant. The catkins are white and are borne in great profusion on the current season's shoots in the late summer and autumn—a character almost unique in Willows. The other is a magnificent, fine foliaged plant. It is a large bush, 10 feet to 20 feet high, with grey-green leaves on red stalks, and I have measured the leaf-blade 8 inches long and 5½ inches wide. The leaves rather suggest those of the Yulan (*Magnolia conspicua*), so much so in fact that when I discovered the plant I momentarily took it for a species of *Magnolia*.

FLOWERING TREES.—An ornamental flowering tree is *Carriera calycina*, with pyramidal heads of ivory-white waxy flowers. It is a much-branched, flat-headed tree of medium height, and the flowers are borne conspicuously at the ends of the shoots. One of the most beautiful of small trees is *Staphylea holocarpa*, with large pendent clusters of pure white to pink flowers borne in profusion before the leaves unfold. The variety *rosea* has rose-coloured flowers, and the leaves are downy on the underside. Both form slender trees 15 feet to 30 feet high, with spreading branches, bright green leaves, and pale green twigs. The flowers are rich in honey and deliciously fragrant.

FOR DRY REGIONS.—A tree which thrives in dry regions is *Pistacia chinensis*. This is one of the largest of Chinese trees and has a very thick trunk, massive wide-spreading branches, which form a flattened or rounded crown; the leaves are dark green, pinnately divided, and in the fall assume wondrous tints of orange and crimson. The flowers are inconspicuous, but the bunches of small fruits, which are rich in oil, are showy, and as they ripen change to scarlet and are finally blue. The wood is valuable, and the young shoots with half-grown leaves are eaten as a vegetable by the Chinese after the manner of Spinach. The Chinese Hog-plum (*Spondias axillaris*) is another drought-resisting tree worthy of extended cultivation. It grows 45 feet to 80 feet high, and has thick branches forming an oval or flattened crown. The leaves are pinnately divided and the oval to ellipsoid yellow fruit is edible, but lacks flavour. In eastern and central China the people consider *Xylosma racemosum* and its variety *pubescens* the most beautiful of all their evergreen trees, and apply to it a name which signifies "Wintergreen." It is commonly planted over shrines and graves and in temple grounds, and has dark, lustrous, green leaves, inconspicuous flowers, and black, pea-like fruits. The branching is dense and the crown wide-spreading, oval, rounded, or flattened, and the short inner branches are spiny.

POPLARS.—A handsome new Poplar is *P. Wilsoni*, with its large, rounded, and slightly-pointed leaves, dark green above and pale on the underside. Other valuable

Poplars suitable for the cooler parts of the Pacific slope, but quite hardy in the coldest parts of this country, are *P. suaveolens* and *P. Simoni*, both quick-growing trees useful for street or park planting.—E. H. WILSON, in *Garden Magazine*.

Euptelea polyandra.—This, in the forests of Central Japan, grows into a tree up to 30 feet high. Here it may eventually grow as tall, for it develops fast and is of free habit, with a generous branch system. The slender and twiggy branches bear light green leaves during the summer, these being of a pretty reddish-brown when developing, and yellow and red in autumn before they fall. Male and female flowers are borne on different plants, the conspicuous part of the male flowers being the bright red stamens. These appear on the leafless branches during March and early April, and, as a tuft of flowers is borne from almost every bud on the previous year's shoots, the effect is very pleasing on a sunny day and is very much like that of *Acer rubrum* and *Parrotia persica*, although the habit of the *Euptelea* is much lighter than that of either of those trees. It should be given a position sheltered from cold winds, for, although quite hardy so far as winter frost is concerned, cold nights and east winds during late spring sometimes injure the young shoots and leaves.—D.

The Downy Manzanita (*Arctostaphylos tomentosa*).—The family of shrubs known as *Arctostaphylos* is represented in the British Isles by two species—*A. alpina*, the Black Bearberry, and *A. Uva-ursi*, the Red Bearberry—both trailing plants found on the Scottish mountains. They are, however, very different plants from the subject of the present note, which is one of several species natives of Western North America, where they are known under the common name of Manzanita. Perhaps the best known species from that region is the common Manzanita (*A. Manzanita*), although it is not widely grown here. *A. tomentosa* is found wild in California and Washington, where it occurs as a bush from a few inches to 5 feet or 6 inches in height, of stunted habit, with extraordinarily twisted and contorted branches. The young wood is hairy, as also are the evergreen leaves, and by that it is easily distinguished from *A. Manzanita*, which is almost, if not quite, glabrous. The urn-shaped flowers, white, slightly flushed with pink, are borne in clusters from the points of the branches during March and early April. Although originally discovered about 120 years ago, it is rarely seen in cultivation, but is represented in the Kew collection, where it succeeds in a mixture of sandy loam and peat. For a sheltered position on the higher parts of the rock garden this shrub is well adapted, and it might be introduced to many gardens in the South of England.—D.

* THE ELM AND THE VINE.

"Uphold my feeble branches
By thy strong arms, I pray."
Thus to the Elm her neighbour
The Vine was heard to say.
"Else, lying low and helpless,
A wretched lot is mine,
Crawled o'er by every reptile,
And browsed by hungry kine."
The Elm was moved to pity,
Then spoke the generous tree:
"My hapless friend, come hither,
And find support in me."
The kindly Elm, receiving
The grateful Vine's embrace,
Became, with that adornment,
The garden's pride and grace;
Became the chosen covert
In which the wild birds sing;
Became the love of shepherds,
And glory of the spring.

—From the Spanish of José Rosas. Translated by William Cullen Bryant.

CHRYSANTHEMUMS.

SEASONABLE NOTES.

Pot plants grown for the production of cut flowers should be placed by themselves so that they may receive suitable treatment. Where many blooms are required from a limited number of plants stopping must be closely attended to. In no case must the plants be left to grow tall with weakly stems before the ends are pinched off to induce a free growth of side-shoots. The latter must not be stopped in their turn too soon, but be allowed to grow 6 inches or a little more. Such treatment applies to the majority of varieties grown for cut blooms. There are two very valuable white-flowered varieties that need special treatment if the best returns are to be obtained. *Mme. R. Oberthur* should be cut back more severely than any other sort, whether the plants be retained in pots throughout the season or planted out for lifting again in the autumn. From plants so treated I have been able to cut nice blooms during this month (March). The other variety is *Mrs. J. Thompson*, and its sports *Buff Thompson* and *Yellow Thompson*. The general habit is much taller than that of *Mme. R. Oberthur*, and any attempt to unduly dwarf it will result in failure. When stopping the plants only remove the extreme point of the shoot, and do not finally stop later than the first week in July. Frequently this variety is over-potted; 9-inch pots are large enough, and I would prefer 8-inch. If larger pots are used put two, or even three, plants into each one.

Plants to bear large blooms must be carefully staked as the stems grow, be freely ventilated in the frames, and kept quite clean. Green-fly and black-fly are troublesome at this stage, and if left undisturbed for several days they cripple the growth of the young shoots. Sprinkle Tobacco-powder on the shoots affected and then forcibly syringe off both the fly and the powder. This should be done every week.

The leaf-mining grub is very troublesome in many collections this season. Very badly-affected leaves must be picked off and burned, but its spread can be arrested if the beginner will closely examine the leaves regularly and press all grubs found between the thumb and finger.

Mildew is found, generally, on the under-sides of the lower leaves, and is a frequent cause of loss of foliage. The best remedy for this is sulphur.

G. G. B.

NOTES AND REPLIES.

Chrysanthemums.—The earliest-rooted lot of Chrysanthemums is now in 5-inch pots. A fairly good compost with a small allowance of soot was made use of for this potting. These plants will all be grown in bush form, and in a short time, after they take hold of the fresh soil, the tips will be pinched out. Meantime they are in a light and airy house, with a night temperature of about 55 degs. Other young plants are making good progress and will shortly be ready for a shift.

Single Chrysanthemum Charles Kingsley.—Many of the single Chrysanthemums are much more effective when grown in a natural way and allowed to bloom in sprays. The fine yellow *Charles Kingsley* is an exception to this rule, for unless the sprays are severely disbudded the full beauty of the flower is, to a great extent, lost. When disbudding is practised the blooms are large, and the variety is one of the very finest of the yellow single Chrysanthemums.—KIRK.

VEGETABLES.

THE POTATO ONION.

This variety more frequently forms a cluster of underground bulbs of irregular shape than a single round bulb. It produces neither seeds nor bulbils, and is increased only from the bulbs which are formed underground. If fairly strong bulbs are planted as early in the spring as the ground can be had in working condition, well-grown bulbs may be had from them in the following June. If, however, the bulbs are allowed to attain full maturity, instead of a single bulb from each, seven or eight of various sizes will be produced. The strongest of these will in their turn produce a number of bulbs, the weaker ones only growing into a single bulb. The flesh of the Potato

large tubers is a mistake. A healthy, clean crop is better than a diseased one of twice the bulk. Raw manure should never be applied to land intended for the growth of Potatoes, but rather induce a medium-sized, hard-wooded haulm than a coarse, succulent one. The freedom from disease of certain kinds arises from the fact that the haulm is of a firm, fibrous nature; and if such kinds be grown in soil of but moderate quality, and free from raw manure, a sound crop may be secured.

Profitable work in cool-houses.—Fuel has become so dear that it has been deemed advisable to give up forcing for a time and use the cool-houses to grow food. At the present there is a demand for good Lettuces. When the Lettuces are cleared off, the Tomato plants may be ready to plant. Tomatoes and Lettuces are only one arrangement, but so far as my ex-

and placed in heat. As soon as the seedlings appear place near the roof glass of a warm pit or house, afterwards removing to a cold frame to harden off preparatory to pricking out into rough frames. Celeriac (Turnip-rooted Celery) is easily grown, and deserves extended cultivation. The roots are excellent when properly cooked, and, as they may be stored in sand in the root-shed for the winter, they form a welcome change in the dull season when vegetables are scarce.

Asparagus-beds.—When necessary the stakes at each corner of the beds will be removed, after which the sides will be made up with soil taken from the alleys. The surface of the beds will also be covered from 2 inches to 3 inches with the finest of the soil, which is levelled down with a rake after a dressing of fish guano has been applied. The alleys will then be

The Potato or Underground Onion.

Onion being milder than that of the ordinary Onion, it is preferred by many people. We have found it a good plan when the bulbs are growing freely to draw some soil up to them. When it is seen that the bulbs are ripening off this soil may be removed in order that sun and air may reach them. This Onion likes good, deep, well-manured soil, and single sets should be planted about 9 inches asunder and 9 inches between the rows. If the ground is soft the bulbs may be simply pressed into the soil, but if firm then it is well to draw out a shallow drill and set the bulbs in this.

Potato culture.—Those who have to purchase their stock of seed tubers should obtain it at once, to make sure of good samples. As regards planting, gross culture for the production of heavy crops and

perience goes it is a profitable one, because they follow each other naturally. When the Tomatoes are finished in the autumn, say at the end of October or later, plant the Lettuces and other salad plants if required. These can be cleared off in March for Tomatoes again after a dressing of wood-ashes and a good treading, as Tomatoes do best in firm soil. Of course, there are other plans which may be adopted for spring and early crops generally, especially if the means are available for making hotbeds on the borders of the house with leaves and a small quantity of stable manure to hold the leaves together and start the warmth in them. On the hotbeds many useful early vegetables may be grown.—E. H.

Celery and Celeriac.—For the main batch of plants seed should be sown about the middle of this month in pans or boxes

repointed and left ready for the planting of a single row of early Cauliflowers later on in each. These will turn in and be out of the way before the Asparagus tops develop to any great extent. Where the practice of dressing the beds with manure in spring instead of autumn finds favour the same should be put on at once, covering afterwards with a little fine soil. With many the difficulty will be in obtaining a supply of manure. Fortunately good substitutes are to be found in salt, or the more valuable fertiliser already alluded to.—G. P. K.

Beet.—Last season a few lines of that old variety Nutting's Dwarf were grown after it had been discarded for several years. Although the season was not, as a whole, quite satisfactory for root crops, this particular Beet gave a good return. The medium-sized, well-coloured roots have been in greater request than those of larger proportions, and Nutting's Dwarf has again been included in the seed order.—KIRK.

ROYAL HORTICULTURAL SOCIETY.

MARCH 28TH, 1916.

THE fortnightly meeting held on this date was smaller than some of those immediately preceding it, albeit there was no lack of interest or variety. Alpines were strongly in evidence and a never-failing source of attraction. Roses, too, were in excellent form, and, like the Carnations, which were also good, are much favoured by visitors. A great bank of *Chionodoxas* revealed the beauty of one of the most precious of blue spring flowers. Orchids were good; the hybrid *Odontiodas* particularly striking and plentiful. Several important novelties received recognition.

ALPINE AND HARDY PLANTS.

In this department the collection of Houseleeks (*Sempervivum*) arranged by

Messrs. R. Tueker and Son, Oxford, was of exceptional interest, albeit the plants would have appeared in better character a few weeks hence. The collection was large, some 168 species and varieties being on view, though but few of the cob-web (*S. arachnoideum*) sorts were noted. In addition, the new *Saxifraga Irvingi* and the rare Italian *S. Borji* (white) were on view.

Messrs. John Waterer, Sons, and Crisp, Twyford and Bagshot, showed many good things, notably the new *Primula Crispi*, said to be a seedling from *P. Julke*, though apparently widely removed from it in general appearance. *Anemone Pulsatilla alba* was both good and abundant, and far better than is usually seen. *Saxifraga apiculata*, *S. a. alba*, and *S. marginata* gave patches of colour. *Narcissus moschatus* was very good.

Messrs. W. Cutbush and Son, Highgate, N., had many beautiful things, the dainty white-flowered *Thalietrum anemonoides*, double blue *Hepatiens*, *Chionodoxas*, *Erythronium giganteum*, and many of the choicer *Saxifragas* being noted. The Winter Heath (*Erica carnea*) gave colour and a beauty of its own.

Messrs. T. S. Ware, Limited, Feltham, had a pan of the exquisite white-flowered *Silene pusilla*, an inch-high alpine of rare beauty. *Trillium erectum* and others were also well shown. *Pulmonaria azurea* (rich blue) merits wider cultivation, being early, dwarf, vigorous, and free-flowering. *Morisia hypogæa* was a carpet of golden flowers.

The best thing in a group from

Messrs. Bakers, Wolverhampton, was *Primula denticulata alba magnifica*, a variety of much merit.

Messrs. G. Jackman and Son, Woking, showed a good lot of *Androsæe Laggeri alba* in flower, its somewhat drawn condition robbing it of not a little of its true character. *Euphorbia Wulfeni*, *Iris pumila*, *I. stylosa*, and Heavenly Blue *Muscari* were also noted.

Messrs. Blackmore and Langdon, Bath, staged a particularly good batch of *Polyanthuses* in white, crimson, golden, and yellow. Obviously a good and vigorous strain. Miss C. M. Dixon, Edenbridge, also showed these easily-grown flowers well, in company with *Auriculas*.

Mr. M. Prichard, Christchurch, showed well-grown alpines in pots, the choicer *Saxifragas*, *Irvingi*, *Faldonside*, *Burseriana macrantha*, *Paulinae*, *latina*, and *Ferdinand-Coburgi* (golden) among them. *Aubrieta Lloyd Edwards* (rich purple) is very handsome. *Orobis vernus albus-roseus* revealed the charm of an old plant too little known or grown.

Messrs. Barr and Sons, Covent Garden, W.C., showed many hardy flowers, notably *Crocuses* and the smaller-growing *Daffodils* as *minimus*, *Queen of Spain*, *cyclamineus*,

mosehatus, and *triandrus* in variety. *Iris tingitana* was among showy things, *Fritillaria armena rubra* and *Helionopsis grandiflora* being not the least interesting.

Mr. Clarence Elliott, Stevenage, had the dainty white-flowered *Soldanella pusilla alba* in degrees of whiteness; also *Saxifraga Irvingi*, *S. oppositifolia latina* (rich red), *S. marginata* (white, very good), *Anemone vernalis*, and *Androsæe Laggeri*, all in good form. Hybrid alpine *Primulas* were also shown.

Mr. Amos Perry, Enfield, again showed some fine varieties of *Shortia uniflora grandiflora*, those named *magnifica* and *rosea superba* being of exceptional merit. A group of *Saxifraga retusa* (rich red) was very fine.

Messrs. Whitelegg and Page, Chislehurst, contributed, among other things, *Arabis aubrietioides* (rose), *Aubrieta The Queen* (rich reddish-lilac, very large), and *Viola gracilis*. *Wistarias* and *Magnolia stellata* were excellent.

Mr. G. W. Miller, Wisbech, showed the more attractive spring flowers, largely *Daisies*, *Polyanthuses*, Tufted *Pansies*, *Primula Juliae*, and *P. denticulata*. *Hepaticas* were very beautiful.

ROSES.

Mr. Elisha J. Hicks, Twyford, showed plants in pots, grouping colonies of the single crimson *Princess Mary* and Mrs. George Norwood (pink, very fragrant) most effectively. Mrs. Elisha Hicks is a novelty, flesh-pink, and highly fragrant. Mrs. John Foster, Mrs. Charles Reed, and Mme. Edouard Herriot were all good.

Mr. George Prince, Oxford, had a splendid stand of Mme. E. Herriot, very rich in colour, as was also the apricot-coloured Mrs. A. R. Waddell. Old Gold was particularly good.

CARNATIONS.

Messrs. Allwood Brothers, Haywards Heath, had an extensive group, the four dozen or so of vases being most effectively staged. The finest things in the lot, however, were the great vases of *Mary Allwood* and *Salmon Enchantress*; the latter, indeed, we have never seen better. White May Day was among newer sorts.

Messrs. W. Cutbush and Sons, Highgate, N., had a particularly good group of *Lady Ingestre*, one of the best pinks, *Marmion* and R. F. Felton being also of special merit.

Misses Price and Fyfe, Birch Grove, East Grinstead, had a novelty in *Grisel*, which gained an Award of Merit. It is of rich reddish-purple colour, fragrant, and of good petal quality. *Pink Sensation* was also very good from this source.

Messrs. Stuart Low and Co., Enfield, also showed these flowers well, *Pink Sensation*, *Gorgeous*, *White Wonder*, *Champion*, and Mrs. C. F. Raphael being excellent.

GREENHOUSE FLOWERS.

In this department we selected the exhibit of *Clematises* by

Messrs. H. B. May and Sons, Edmonton, as the most useful and suggestive of the occasion. Greenhouse-grown, without appreciable loss of colour, their utility was at once demonstrated. That fine white *Miss Bateman* was in striking contrast with the red-barred *Nellie Moser*, and the twain are indispensable indoors or out. *Lady* and *Lord Londesborough* and *The Queen* (all mauve or lavender shades) were very good.

Messrs. R. and G. Cuthbert, Southgate, N., showed *Hyacinths* in pans, many of the best sorts appearing in perfection. *Corregio* (white), *Perle Brilliant* (porcelain and pale blue), *Schotel* and *Grand Maître* (light and deep blue respectively),

and *Jacques* and *Moreno* (pink) were some of them.

Messrs. H. Cannell and Sons, Eynsford, Kent, had two or three dozen vases of winter-flowering *Pelargoniums*, their brilliant shades attracting many. *George Costerline* (lilac-pink), *Gemini* (orange-crimson, white centre), *Louis Chauvin* (salmon); *Firefly* (one of the most striking), *John Stares* (orange-scarlet), and *Golden Lion* were a few of the more striking.

Messrs. Sutton and Sons, Reading, had an instructive exhibit of *Lachenalia Nelsoni*, staging some hundreds of exceptionally well-coloured spikes of flowers. The value of the exhibit lay in the fact that the plants had received only cold-frame culture, hence, doubtless, the sturdiness of the spikes and the richer flower-colour.

Messrs. R. H. Bath, Limited, Wisbech, contributed a large collection of Darwin *Tulips* grown in bowls of fibre. Nothing could have been finer or more suggestive of the possibilities of this phase of indoor gardening. *Narcissus Centurion* (Award of Merit) (a bicolor *incomparabilis*) was with others similarly grown. It is excellent. The end of the exhibit was a bank of the gorgeous blue *Chionodoxa sardensis* and others.

FLOWERING SHRUBS.

Messrs. J. Cheal and Son, Crawley, showed several good things, *Cytisus Dalimorei*, *Osmanthus Delavayi* (white), *Pieris floribunda*, *Daphne Cneorum*, and *Erica australis* being noted. Alpines in flower were used at the margin.

Mr. L. R. Russell, Richmond, showed freely of *Indian Azaleas* in variety, *Anthony Koster* (of the *mollis* section) making a big show with its trusses of rich yellow flowers. *Lilacs*, *Wistarias*, and others were also good.

NARCISSI.

Messrs. Carter and Co., Raynes Park, S.W., contributed a sumptuous group of *King Alfred Daffodil*, than which nothing so fine has ever been staged. There were approximately 800 flowers of this unique yellow *Ajax* set out in an undulating bank, flowers at once brilliant in colour and of refined beauty.

Messrs. Barr and Sons, Covent Garden, W.C., staged a collection rich in beauty and novelty. A few dozens of *King-Alfred* were of superb colour, very telling even amid the surrounding wealth of these flowers. *Sunrise* (a notable *Barri*), *Mermoid* (an exquisite *Leeds*), *Peter Barr* (still unequalled among white *Ajax* sorts), *Vivian Gosnell* (creamy-white *Ajax*), *Golden Comet*, and *Golden Sun* (very richly-coloured trumpet sort), and *Battle-axe* (*incomparabilis*) (golden-orange, almost cylindrical crown, and pale-yellow perianth) were among the best.

Rev. G. H. Engleheart had half-a-dozen flowers, of an *Ajax* sort, with clear, full, salmon-coloured trumpet. The variety was not on exhibition, but we were privileged to get a glimpse of it. Obviously, it is a good stepping-stone to greater things.

ORCHIDS.

Messrs. Sander and Sons, St. Albans, showed a group of rare species, including *Cœlogyne Lawrenceana*, *C. ochracea*, with some pretty *Maxillarias*.

Messrs. Charlesworth and Co., Haywards Heath, contributed a superb lot of *Odontiodas*, notably *Zenobia*, *Brunette*, *Charlesworthi*, and many others. Amid white *Miltonias* and *Odontoglossums*, the reds and crimsons of the *Odontiodas* were very telling.

Messrs. J. and A. MacBean, Cooks-

bridge, Sussex, had excellent *Odontoglossum crispum* (spotted varieties), also *Laelio-Cattleya The Pearl*, and *Odontioda Bradshawae* and *O. Charlesworthi* among others.

Messrs. Stuart Low and Co., Enfield, showed the yellow-flowered *Dendrobium Brymerianum*, and the white-flowered *D. Jamesianum*, also *Brasso-Cattleya Queen Alexandra*.

FRUIT AND VEGETABLES.

Mr. G. W. Miller, Wisbech, staged a superbly-grown lot of *The Sutton Rhubarb*, quite remarkable for its brilliant colouring.

Messrs. J. Cheal and Sons, Crawley, showed Apples *Encore* and *Crawley Beauty* (both cooking sorts) in a fine state of preservation.

Mr. E. Beckett, Elstree, showed bulbs of *Onion Autumn Triumph* from a sowing made in August, 1914. They were of medium size and very firm.

A complete list of the certificated plants and medals awarded will be found in our advertisement columns.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM MARCH 23RD.—*Berberis* (in variety), *Cydonias* (in variety), *Andromedas* (various), *Daphnes* (in variety), *Rhododendron venustum*, *Skimmias*, *Almond*, *Periwinkles*, *Osmanthus Delavayi*, *Forsythia spectabilis*, the *Goat Willow* (*Salix caprea*), the *Cornelian Cherry*, *Ericas* (in variety), *Laurustinus* (various), *Azara microphylla*, *Ribes sanguineum*, *Alnus* (various), single pink *Camellia*, *Scilla taurica*, *S. sibirica*, *S. campanulata*, *Puschkinia scilloides*, *Muscari botryoides*, *Hyacinthus azureus*, *Anemone Hepatica* (in various colours), *Anemone angulosa* (in variety), the *Greek Anemone* (*A. blanda*) (various colours), the *Poppy Anemone* (*A. coronaria*), *White Wood Anemone*, the *Pasque-flower* (*A. Pulsatilla*), the *Scarlet Windflower* (*A. fulgens*), *Chionodoxa Luciliae*, *C. sardensis*, *C. gigantea*, *Snowdrops* (in variety), *Violets* (in variety), *Polyanthuses*, *Violet Cress*, the *Netted Iris* (*I. reticulata*), the *Algerian Iris* (*I. stylosa*), *Crocus* (in great variety), *Arabis* (single and double), *Saxifrages* (various), *Narcissus minimus*, *N. maximus*, *N. pallidus praecox*, *N. Grand Monarch*, *N. Tazetta*, *N. Telamonius plenus*, *N. odoratus* (*Campernelle*), the *Tenby Daffodil* and others, *Snowflakes*, *Dog's-tooth Violets*, *Forget-me-nots*, *Lenten Roses* (various colours), the *Corsican Hellebore*, *Corydalis cheilanthisifolia*, *C. cava*, *Candytuft*, *Winter Aconites*, *Wallflowers*, *Lithospermum rosmarinifolium*, the *Bardfield Oxlip* (*Primula elatior*).

WORK OF THE WEEK.—A start has been made with the pruning of dwarf *Roses*, those occupying beds facing south and protected from north and east by high walls being dealt with first. There is usually much hair-splitting about pruning, but if the *Roses* are in a healthy condition the work is quite easy. As the pruning proceeds attention should be given to the clearing and forking up of the beds. In some beds *Tufted Pansies* have been planted as a groundwork, while in others will be sown next month choice dwarf annuals, and in suitable positions dwarf plants of various kinds will be used. A bed of pink *Roses* has for some years been carpeted with *Tropæolum polyphyllum*. As this is permanent, and has made considerable growth, the forking over required much care, otherwise the young shoots would have been badly damaged. The same applies to a bed of *Rose Edith Giffard*, which is carpeted with the *Greek Anemone* and *Chionodoxa gigantea*. A further supply of *Erica mediterranea hybrida* has been planted at the base of a group of *Lawson's Cypress* and *Snowdrop-tree* (*Halesia tetraetra*). Another batch of the *New Zealand Reed* (*Arundo conspicua*) and *Gynerium Rendatleri* has been relieved of their old foliage, and the ground among the plants well exposed to the weather by deep digging. A start has also been made with the forking over and freshening up of the mixed border as most of the plants can now be seen. At the same time great care is necessary, especially where recent additions have been made. A number of *Pinus ponderosa* and *Cupressus macrocarpa* has been put out. The former is intended for the woods, but as the position is not yet ready the trees have been planted 2 feet apart in the reserve garden. The latter being small seedlings have been put out in lines 6 inches apart. A few bulbs of the *Taurian Scilla* have been given a favoured place at the foot of a sunny wall. A bed has been edged with the dwarf silvery *Santolina Chamæcyparissus squarrosa*, and another with *Wahlenbergia vinæiflora*. The beds are 6 inches above the ground level, with an edging of paving-stone, over which the plants are

intended to fall. The autumn-sown *Sweet Peas* have been staked with small *Birch* sprays; the larger stakes will be added later. *Sweet Peas* sown early in February have been transferred to cold frames. In a large bed planted last year with the *Scarlet Sword Lily* (*Gladiolus Brencleyensis*) the bulbs appear to be in excellent condition. These will be given a carpet of some blue-flowered plant later on. E. M. Sussex.

SOUTHERN COUNTIES.

Outdoor Figs.—Where necessary to protect trees grown against walls outside from frost with *Bracken* held in place by mats or by some other means, part of the same should now be dispensed with and the remainder in the course of another week or ten days. The trees should then receive whatever attention they require in respect to the thinning out of almost fruitless branches—i.e., those which carry fruit at their extremities only—and in carefully pruning away surplus young wood when more than was necessary was laid in during last season. When doing this, care must be taken to see that the most fruitful of it is retained, evidence of which is plainly visible if an examination of the shoots is made. The embryo fruits will be found situated at the joints on the shoots throughout their entire length if the roots of the tree are under control and the wood thoroughly ripened. Many err in leaving partly developed fruits on the branches under the impression that such will in due course swell to maturity, whereas they do but drop as soon as the tree gets into full growth. All fruits found in this stage of development should, therefore, be pulled off at pruning time. The removal of a branch here and there as suggested will leave more space vacant for the training in of young bearing wood in the lower part of the trees. Advantage should be taken of this fact during the coming season to get such space properly clothed with suitable growths. Re-fastening of the branches to the wall should succeed the pruning, using stout tar-twine for the largest, and the same kind of twine of a less size for the remainder. A top-dressing of fibrous loam containing a plentiful supply of lime-rubble and a small quantity of bone-meal may be afforded the border if deemed necessary, but any other kind of stimulant must be held over until the fruits commence swelling again after the flowering period is past.

Main crop Peas.—A good sowing of these, consisting of several varieties to ensure a continuous supply has been made, and another will take place in a fortnight.

Main crop Carrots.—Although sowing cannot, owing to the wet state of the soil which this crop is to occupy, be done, the surface, as a preparatory measure, has been forked over, so that air can freely penetrate and dry it. Sowing in former years has usually been done about the second week in April, but this season it will take place directly the soil can be caught in the desired condition—i.e., when it has dried sufficiently so that it can be broken down easily. A good seed bed will then result.

Shorthorn Carrots.—Another good sowing of *Early Gem* and *Model* will now be made between the rows of main crop *Peas*. These will be drawn and used when young, and will not, therefore, occupy the ground for any great length of time or interfere with autumn cropping arrangements. Later sowings will be made on a border facing west.

Broad Beans.—A further sowing of the *Longpod* and *Green Windsor* varieties will be made on firm ground. These later sowings have to be netted over to prevent rooks destroying the young plants just as they peep above ground.

Cucumbers.—A hotbed was made up in a brick pit some weeks ago, but planting was deferred until milder weather set in owing to the difficulty of maintaining a suitable temperature while the cold spell lasted. The plants—to prevent them becoming pot-bound—were shifted into larger pots, and have accordingly made a good deal of growth, but they will now be planted out. Mounds of loam enriched with leaf-mould and spent *Mushroom* dung have been placed in the centre of the bed under each light, and as soon as this has become warmed through plaiting will take place. The plants, having a good length of stem, the balls, to avoid any bending and rupturing of the sap-vessels, will be laid on their sides in the holes opened for their reception. To secure an ample supply of side shoots for the furnishing of the bed with bine the points of the plants will be stopped directly the roots have obtained a grip of the compost. To prevent the rising of ammoniacal vapours from the bed that portion of the surface not occupied with compost has been covered with leaf-mould. Tepid water will be used to settle the compost round the balls, also for syringing and sprinkling the surface of the bed on fine days. For some time to come the admission of air will have to be done with care, and whenever possible a high temperature will be secured by closing as early as is compatible with safety. A heap of compost for top-dressing will be mixed for future use, so that it may be ready to hand whenever required. To avert loss of heat on cold and windy nights the sashes will be double matted at dusk. Seeds will be sown now to obtain

plants for setting out in frames when cleared of *Potatoes*, *Celery*, etc. The hotbeds on which they now stand will retain sufficient heat for their requirements.

Forced Cucumbers.—Plants raised early in January and now coming into full bearing must not, if they are to continue yielding fruit for some time to come, be over-cropped. Another thing which helps to avert the over-taxing of the plants' energies is to at once cut away any fruit of usable size. To maintain vigorous growth is another item which must not be lost sight of. Every attention, therefore, has to be directed to the top-dressing, which is far better afforded on the "little-and-often" principle than in great quantities at one time. Whatever additions may be made to it, loam should form the bulk of the compost used for this purpose, and the more flaky and fibrous it is the more will it be appreciated by the roots. Other aids to the maintenance of vigour and fruitfulness are tepid manure, guano, and soot water, and now and again a little nitrate of soda, which should be dissolved in the water when the latter is about to be applied. The trellis must be kept well furnished with young growths, which should be stopped at the first or second leaf beyond the fruits. To prevent overcrowding, a little of the old bine should at intervals be cut out. Syringing may now be freely indulged in both morning and afternoon, and damping down done in accordance with outer climatic conditions. Sprinkling the floor at closing time with liquid manure also acts as a vitaliser. To economise fuel, the most should be made of sun heat. By closing early or in time to secure a temperature of 90 degs. to 95 degs. sufficient heat will be bottled up to serve for several hours without having recourse to extraneous aid. A. W.

MIDLAND COUNTIES.

Early Vines carrying a full crop of fruit will be given a good mulch of farmyard manure as soon as the berries have stoned, washing this in with tepid water on a bright morning when air can be admitted at the top of the house. The trellis being now well furnished with foliage all growths must be kept pinched. The bunches will need looking over again, and small, seedless berries carefully removed. Succession *Vines* started in January are now making rapid progress. Continue to regulate the growths and stop the laterals, but avoid overcrowding the principal leaves. A temperature of 65 degs. is suitable at night for the flowering season of most varieties, excepting *Muscats*, the temperature for which should be 5 degs. higher. Maintain a moist atmosphere. Ventilate freely early, on fine days close early and avoid a too high night temperature. Commence to thin the berries as soon as it can be seen which are swelling. Remove all surplus bunches, and avoid over-cropping. Sprinkle the paths and borders at night with weak liquid manure. Disbud late *Vines*, and tie down as growth advances. Do not keep too close an atmosphere in these houses, but secure strong, healthy foliage by free ventilation and moderate night temperatures.

Caladiums.—Plants growing freely may be finally repotted in light, rich soil, which should not be made very firm. These plants require an abundance of water when growing freely, therefore it is necessary to provide ample drainage. They must be shaded from strong sunshine, otherwise all the light possible should be afforded to bring out the colour of the leaves.

Perpetual-flowering Carnations.—The earliest-rooted batch is now ready to be repotted into 6-inch pots. The pots must be scrupulously clean and well drained. A suitable compost consists of two-thirds good fibrous loam, one-third well-decayed manure, adding a little old mortar-rubble, sand, soot, and bone-meal, mixing all thoroughly. Firm potting is essential. When potted, the plants are returned to the house for ten days or a fortnight, after which they will be placed in cold frames.

Tritomas.—The present is a suitable time to divide and replant these. Even if there is no need to part them for increase of stock, they flower much better if it is done every three or four years and the clumps relieved of some of the weaker growths, which are liable to choke the stronger-flowering crowns. When the plants are lifted, take the opportunity to thoroughly enrich the soil by digging in plenty of decayed manure, and increase the depth of good soil if possible. Plant with the crowns well below the surface-level, and do not heap the soil round them higher than the surrounding level, as they are moisture-loving plants. It is far better to form the soil into a kind of basin than to mound it up.

Ivy.—Early in April is the best time for clipping *Ivy*. That growing on walls should be clipped every year, cutting away all leaves and projecting growths. When treated in this way it looks unsightly for a week or two, but new growth soon appears. This annual clipping also assists the clinging aerial shoots, for it relieves them of much weight, and walls are not so likely to be stripped in high winds.

Calceolaria amplicaulis struck and wintered in cold frames now requires to be transplanted. A bed of soil will be prepared on a hard bottom of coal ashes in cold frames.

The plants are lifted with a trowel, and replanted about 4 inches apart each way. The soil should be loamy with an admixture of half-rotted leaf-soil, or manure from a spent Mushroom bed. The plants can then be lifted with good balls of soil when transferred to the flower beds.

Annuals sown in heat are pricked off into frames or potted singly as becomes necessary, and grown on sturdily, protecting thoroughly from cold at night.

Beet.—Although as yet too early to sow the main crop of Beet, a sowing of the Turnip-rooted variety will be made now on a warm border to afford an early supply of roots.

Turnips.—Successional sowings of small varieties of Turnips will be made at regular intervals, giving a dressing of wood-ashes in the drills at the time of sowing. Birds, especially Sparrows, are very destructive to all kinds of seedlings. A sharp look out must be kept as the Turnips come through the ground, and if not convenient to net the bed frequent dressings of soot and lime will be necessary.

Brussels Sprouts, Cauliflowers, etc., from early sowings must not be allowed to get too big before they are pricked out into cold frames. Lettuces can be pricked out in such a way that every second plant may be lifted in two or three weeks for transplanting out-of-doors, whilst those left in the frames are coming on for early use.

Tomatoes.—Keep the seedlings close to the glass to prevent them becoming drawn. Pot off singly as soon as ready into small pots, using a mixture of good loam, wood ashes, and mortar-rubble. Do not pot too firm, and keep the plants in a house or pit having an atmospheric temperature of 55 degs. to 60 degs.

Potatoes in frames.—The present is a critical period of growth with frame Potatoes, as if forced too hard the top growth will be in advance of the roots, and the tubers will be poor in consequence. Ample ventilation in fine weather is essential, and there should be no lack of moisture. Frame Potatoes are often checked through dryness at the root. With growth well advanced, occasional supplies of weak liquid manure given in a tepid state will be well repaid. Plants in unheated frames need less moisture, and should be protected from cold draughts or rain.

F. W. GALLOR.

SCOTLAND.

Rose pruning.—Considerable progress has been made with the pruning of Roses in the course of the week. Climbers were well thinned out in the autumn; but a look over was given at this time, and the needful regulating and tying of the shoots were attended to. It is always advisable to prune Hybrid Perpetual varieties first, then the Hybrid Teas can be seen to, while the more tender Teas are better left until the opening weeks of April. China Roses are better deferred until that time, and but little pruning is needful in their case. In the case of such as Hugonis, Persian Yellow, Austrian Yellow and the old Scottish Roses, it is sufficient to cut out the dead or twiggy wood. No hard-and-fast rules can be applied to Rose pruning, but a few general points may be mentioned. Cut out all old or decayed wood, next all spindly and weak growths, and then prune the remaining healthy shoots back to three or four eyes. Where such straggling varieties as Melody are grown, it is well to prune back to an eye which points upward, even though rather severe cutting back has to be practised. In the case of such erect and vigorous growing kinds as General MacArthur, Betty, Harry Kirk, Caroline Testout, and similar Roses, if they are grown in beds or in borders closely, they may be cut back, as advised, to three or four eyes; but where they are grown singly with plenty of room for extension, it is sufficient merely to tip the shoots. By following the latter practice massive bushes may be formed, which will produce exceptionally large quantities of bloom. All newly-planted Roses should be cut back to within a few eyes of the base of the plants. In the case of dwarf Roses, flowers may be expected during the season, but as regards Climbing Roses, no bloom need be looked for. It is better, however, to follow this method, for by doing so good plants are built up which will flower profusely during succeeding years.

Dahlias.—A beginning was made in the course of the week with the propagation of Dahlias from cuttings. These are taken either with a heel or with a small portion of the parent tuber adhering. Propagation will during the present spring be more limited than usual, and the cuttings are inserted in pairs in 5-inch pots filled with light sandy soil, and in which they will remain until they are ready for planting out some time in May.

Lupins.—Following the usual custom practised in these gardens, a considerable amount of seeds of different kinds of Lupins was sown. If seeds are sown in the open birds destroy a large proportion of them, and there is in any case a considerable wastage in thinning where the seeds are unharmed. Further, the thinning does not readily transplant, so that sowings are made in quite small pots, three seeds in a pot. The strongest seedling is ultimately given the entire space, and, having formed a compact ball, the plant can be put in any desired position without a check. Meantime,

the pots are placed in an unheated house, and the watering carefully attended to.

Plant-houses.—There is now no scarcity of bloom, although the display is to some extent discounted by the increasing attractions out-of-doors. In the stove, climbing plants were looked over, cut back, or thinned, as individual cases required. The old Begonia Rex is receiving more attention than has been the case for a series of years, and in the course of the week some old plants were broken up and repotted, while younger pieces raised from leaf cuttings were placed in conveniently sized pots. A good roof plant of Bougainvillea Sanderiana was retained. This is a serviceable plant, flowering almost continually, and is to be preferred to *B. glabra*. Propagation goes on as seems to be necessary. Stove heat at night may run to about 63 degs., and with the milder weather now experienced this night temperature can be obtained without excessive firing. Air is admitted during the day when the thermometer indicates 80 degs.; but early closing is practised, and the syringe is now freely used morning and night. In the greenhouse, Cinerarias and Primulas are now outstanding. The former, chiefly of the stellate type, are very showy, and useful alike for decoration and for cutting. Zonal Pelargoniums will shortly be in bloom, and tuberous Begonias make good progress. A further batch of these useful plants was potted up during the week, and a quantity of *B. Weltoniensis* cuttings was put in. Another good variety in the shape of *B. coralina* is also made use of, cuttings of this being put in at the same time. *B. coralina* is also useful in the stove, but it grows well as a rafter plant in a warm greenhouse. A large planted out piece of Heliotrope was cut back, this having outgrown its bounds. Although the space is at present a trifle bare-looking, growth soon follows in the case of cut-back Heliotropes, and the space is soon refilled. A large piece of Zonal Pelargonium Rada, also planted out, was thinned at the same time. This is a capital variety for planting out, and is almost always in bloom. The old growths of the climbing Fern, *Lygodium scandens*, were cut away in order to permit the young fronds to get up, and some training was done in the case of *Mandevilla suaveolens*. Arum Lilies are now very free, and are being regularly assisted with stimulants. As aphid is now apt to make its appearance, a close watch is being kept for possible attacks on these plants. In a cool house *Valloata*, *Crimmum*, and *Nerines* are receiving the attention which they individually require.

Cold frames.—Large quantities of Spanish Irises, English Irises, Gladioli The Bride and Ackermannii, *Ixias*, and *Sparaxis* are grown in cold frames for cutting. Some time ago these were top-dressed, and now that growth is advanced the beds were hand weeded and a further dressing of light, rich soil applied. With the increasing sun heat much more moisture is now necessary, and it is found to be of more service to give a thorough soaking at stated intervals than to look over them daily. Such things as *Calceolarias*, *Pentstemons*, *Tufted Pansies*, and the like now likewise require periodical waterings. Any spare frames are being got ready in anticipation of the pricking-off season now at hand.

Tree Peonies.—These are exceptionally far forward for the date, and, owing to the prevalence of frosts and of cutting east winds some anxiety has been felt. So far no damage has been noticed, and during the week the plants have been assisted either by means of top-dressing or by forking in lightly an allowance of well-rotted manure round the roots.

Laurels.—There are not now so many Laurels as was at one time the case, these having been grubbed out and replaced with flowering shrubs. This is the best time at which to cut back the survivors, and if the cutting is done just now the ensuing season's growths will soon efface the marks of shears or of hedge-knife.

Vegetable garden.—More Potatoes have been planted; these including such varieties as Puritan, Sir John Llewellyn, and The Factor. Jerusalem Artichokes were also planted. The white variety has now replaced the older purple sort. It is equally prolific, and, being shallower in the eye, there is not so much waste, while the quality is equally good. A few lines of Early York Cabbage were planted to succeed those planted in autumn. The soil was loosened between the lines during the week, a dressing of soot having previously been given. A sowing of Chervil was made, and this will be repeated at intervals till mid-summer. Asparagus beds have now been thoroughly cleaned and stirred up. These, as formerly mentioned, will be allowed a good dressing of compound concentrated fertiliser. A small sowing of Victoria Round Spinach was made. This variety is superior to the ordinary Summer Round variety. Spinach Beet, which has stood over the winter, is now growing freely, and will shortly be ready for picking at a time when green vegetables are none too plentiful. Celery having come to an end, the quarter occupied by the trenches has been levelled and dug over. This portion will be utilised for maincrop Carrots and for Turnips. Full sowings of Celery for maincrop purpose were made during the week, the varieties used being Wright's Grove White, Major Clarke's Red, and Wright's Grove Pink, all useful and reliable sorts.

Balmae Gardens, Kirkcudbright.

CORRESPONDENCE.

PLANTS AND FLOWERS.

Flower-buds falling off Zonal Pelargoniums (Zonal).—It is difficult to say what causes the flower-buds to fall off these plants without knowing their condition and treatment. Gas would make the buds fall, so would too much or too little water applied to the roots, or if there are worms in the pots, and the drainage is imperfect; cold draughts of air will also cause the mischief; in short, a check of any kind will do it.

Aspidistras of bad shape (H. E.).—These plants have a tendency to push out the creeping root-stock in one direction. Little can be done to improve the shape of the plant (beyond, of course, placing it exactly in the middle of the fresh pot), though if you like to try the experiment it might be divided longitudinally into two equal parts, and the one part turned round so as to extend the other way. This would probably mar the appearance of the plant for a time, but improve it subsequently. Yes, soot-water given in moderation is an excellent fertiliser.

Planting out Carnations (Carnation).—We presume the plants are now in small pots, either singly or in pairs, because the Carnation does not like to be disturbed much at the roots in the spring; and if they were planted out in the frame, the check would be too serious to be thought of. When they are planted out from small pots they do not seem to suffer much by the change. Plant them out whenever the ground and the weather are favourable. Let the ground be deep and rich, and the plants should be inured to the open air by free exposure before planting out.

Starting Begonias (B.).—The tubers certainly ought to be shaken out and repotted, though this may be done either before or just after they commence to start again. It is better and safer to start them in quite small pots, shifting them on as they grow. A cold frame is hardly a suitable place for the tubers thus early, though from about the middle of April they would do nicely there, but on cold night a mat or two should be spread over the glass even then. Can you not start them in a sunny window, and remove to the frame in April? There is plenty of time to start them yet for ordinary purposes, however.

Maiden-hair Ferns (Pteris).—All depends upon what is understood by a cool conservatory whether these Ferns will succeed in it or not. They will not succeed in an unheated house, nor in one from which the frost is just excluded; moreover, the dry atmosphere of an ordinary conservatory is not adapted to their requirements, especially in winter. The plants of these, usually sold in shops, are grown in warm hothouses, in a moist atmosphere, and when removed to less congenial quarters most of the fronds die off. If they are placed in a conservatory they should be at the warmest end, and must not be exposed to draughts.

TREES AND SHRUBS.

The Purging Cassia (C. Fistula) (E. V. Brickenden).—This is the name of the plant the seed-pod of which you send us. It is also known as the Pudding Pipe-tree from its peculiar pods. It is a very handsome tree with the foliage of the Ash and the inflorescence of the Laburnum. It is a native of India, but has been introduced into the West Indies, Northern Africa, etc., whence its pods are imported. The interior of the pod is divided into a number of compartments, each compartment containing a single seed embedded in pulp, which is used as a mild laxative. The genus Cassia is important from a medical point of view as it produces the well-known drug senna.

SHORT REPLIES.

A. H.—The only book likely to answer your purpose, seeing you limit the price, is "Villa Gardening," price 2s. 6d. net, from this office. —**A. L. Morgan.**—Red lead would be of no use, the only way being to net the ground over or use strong cotton thread strung to pegs fixed all over the ground that has been sown down. —**N. H. Evans.**—If you can get rotten stable manure much the ground all over with this. The rains will wash the goodness of the manure down to the roots of the plants. Now that the various plants can be seen, it is an easy matter to lightly fork the manure into the ground if you object to its lying on the top of the soil. Do not use a spade to dig the manure in. For the Palm, very weak soot-water will be as good as anything you can use.

NAMES OF PLANTS AND FRUITS.

Names of plants.—**M. M. Beal.**—Probably an *Antholyza*, but we must have flowers to name with any certainty. —**W. H. Arnall.**—Impossible to name from a half-decayed leaf. —**Casterton.**—*Narcissus minor*.

POOR FORM OF GOOD TREES AND PLANTS.

LOOKING ONE morning in March at my little bank of scarlet Anemone (*A. fulgens*), so very pretty among the Heaths, I was reminded that it first came into cultivation as a double flower long before we took up this brightest Windflower of the spring. In France the double form of it, under the name of Peacock Anemone, was in gardens first, and it is curious to see how sometimes the poorer forms of plants come into cultivation first. For instance, we had the male Butcher's Broom, a most wretched thing, and one wondered why anyone could grow the male form, whereas if we take the trouble to get the fruiting form of it it is a handsome winter ornament. For long years the spotted form of the Aucuba was in gardens. Long afterwards came the green forms, far more precious as evergreens, some, best of all evergreens.

Again, many things are spoilt by doubling. That most graceful flower of the northern world, as one thinks it to be, the Clematis of Japan and China, and also European kinds, the nurserymen have taken a dismal pleasure in doubling. I have never ordered a double Clematis in my life, but somehow double forms have crept into my collection, and hideous they are. The double Camellia, again, is not nearly so graceful as single kinds, and the attention given to the double kinds took away for a time the care for the single ones, the only ones worth growing in our country. The Camellia is hardy in the South of England and in Ireland.

The folded umbrella trees are brought out for their many forms, unlike their natural shapes—pyramids, Irish Yews, and varieties of Cypress. Lately the snow has got in among the branches, smashing the boughs and giving much unworthy labour to gardening men. Very few of these malformations have any true beauty of form, and in their wild states are much more precious. A few Conifers, like the Eastern Cypress, are naturally pyramidal, and that is quite beautiful.

Variiegated trees, too, are often a dreadful deviation from beautiful colour and form, and even diseased, and always ugly. The worst of all offenders in this way are the sports of the Western Arborvitae. In its native land it is not a beautiful tree, but our nurserymen brought out forms of it dreadful to see in their effect. The worst offender among

the variegated trees is the white-washed Maple (*Acer Negundo variegatum*), a very ugly addition to the colours of a fair garden. A very ugly variegation is that of the common Elder, of which there are two or more variegated forms, which with the wild mother plant (*Sambucus nigra*) had better go on the fire heap, so far as gardens are concerned. The Sycamore, a fine tree in its natural colour, is sickly looking in a variegated state. The wretched common Privet, an ugly bush in its green state, is a public nuisance in its variegated form, stupidly bestrewn over the earth by men who have no sense of what true colour is.

The most fatuous attempt at the spoiling of beautiful trees is seizing any variegated form, naming it, and sending it out as a new thing—a hideous mistake. Many of these variegated Pines and Cyresses have been sent out, but they usually perish of disease, and, in any case, should not be seen in any garden where the nobler evergreen trees are cared for.

W.

NOTES OF THE WEEK.

A note from Cork.—The storm fortunately never reached our shores, and now spring is fast advancing, with the Daffodils, Primulas, and Anemones well started.—RICH. H. BEAMISH.

Raoulia australis.—This is a charming, very dwarf silvery carpeter, white in winter as well as in summer. It is a gain to the close-growing, Moss-like plants for the choice rock garden or raised dry border. From Sir F. Crisp.

Growing Iris reticulata.—The precious quality of lasting long in the house mentioned in GARDENING ILLUSTRATED reminds me of several failures to grow it in my cool soil. Some of your readers might kindly tell us of the soils in which it does best. It is worth growing for its use in the house alone. Its beauty is quite extraordinary, and it were better to grow it in paus than be beaten in the open air. Slugs are said to be among its enemies.—W.

The May Flower (Epigaea repens).—There are so many failures with this charming creeping shrub that it might be well if any readers would tell us of the conditions where it thrives. In its own country acres of it may be seen in dry, sandy soil under Pine trees, and no doubt in other conditions. It should be a charm-

ing rock shrub, and now that so many are making rock gardens a home might be found for it. The imported plants often come over with the roots too dry.—SURREY.

Hellebores as cut flowers.—These will last much longer if they are entirely immersed in cold water for a whole night before being put into the vases they are to occupy. If they begin to flag early, this process may be repeated. If this is done, and they are kept in a cool room, they will stand for some days. I have had them for about a fortnight in a room without heat. This applies to both the Christmas and Lenten Roscs.—S. A.

The Great Pilewort (Ranunculus Ficaria).—Among the hardy plants that have cheered this dismal spring this is noteworthy, as it held its handsome buds and flowers well up after the snow left. It is not difficult as to soil, blooming well on a poor sandy bank. It is a giant form of our little Lesser Celandine, but precious as a garden plant. Its fine qualities lead me to plant it in the Heath garden. It is probably now rightly named a Ranunculus.—W.

Plants for limeless soil.—I am going to plant a wild garden in a beautiful but rather desolate and wind-swept part of the Graupian Hills—about 800 feet above sea level—on ground which is either peat or quite limeless soil. Would any readers of GARDENING ILLUSTRATED kindly tell me of any plants or shrubs that would flourish in such soil—not including Rhododendrons, Azaleas, Junipers, Ericas, Lithospermums, Thymes, all of which I have already? I should be grateful to know which Daphnes would do up there, and Lilies besides *L. pardalinum*. I have a rushing rock burn and should be grateful for names of anything that would grow in such soil and surroundings.—LADY STRATHMORE, Glamis, N.B.

White Mignonette (Reseda alba).—Reseda alba is a distinct species, and is not to be confounded with any white variety of the common Mignonette (*Reseda odorata*). Although not so fragrant as the popular favourite, yet the white Mignonette has other and stronger claims to attention. Its beautifully-cut foliage at once distinguishes it from the common Mignonette, as do its giant spikes of brown-anthered white flowers, rising to a height of 2 feet or more above the ground level. In Nicholson's "Dictionary of Gardening" it is described as a biennial, but it can be treated as a half-hardy

annual, or even as a hardy annual. In fact a good stock of self-sown plants often appears in the spring where it has been grown the previous summer. Unfortunately it is seldom included in our seedsmen's lists.—ALBION.

Galanthus Elwesi Whittalli.—The large flowers of this Snowdrop have been much admired this year. They are pure white and borne on stout stalks, each from 6 inches to 8 inches in height, from which they gracefully droop. When fully expanded the flowers each measure $2\frac{1}{2}$ inches across, and when closed are 2 inches from stalk to tip of petal, while a single petal is 1 inch in width. It will therefore be seen what an unusual flower this is. If not quite so elegant as *G. nivalis* it is, nevertheless, an exquisite Snowdrop, seen at its best, perhaps, when closed. The bluish-green leaves are a little longer than the flower-stalk. One bulb in this batch has produced two flowers on a single stalk the last two seasons.—E. M.

Echinopsis Decaisneana.—I am much interested in your illustration of *Echinopsis Decaisneana* in your issue of April 1st. Schumann considers this species as indistinguishable from *E. gemmata* K. Sch. (syn. *E. turbinata* Zucc.), but as figured by you it is markedly distinct in the form of the stem. In *E. gemmata* the stem is globular or top shaped, and does not exceed about 7 inches in height, while the ribs are entire. In your illustration, in proportion to the flower-tube the stem appears to be about 18 inches high. The distinctly divided ribs, too, are totally unlike *E. gemmata*, and are very similar to *E. calochlora* K. Sch., in which species the stem also is columnar. Unfortunately I have not so far succeeded in flowering *E. calochlora*, and cannot therefore compare the two species in this respect, but as it has the reputation of being a very shy flowerer it seems unlikely that you have confused the two species.—R. A. TODD.

The Butcher's Broom (*Ruscus aculeatus*) in fruit.—On one of the dullest days of the wet month of March a bunch of this, full of brilliant fruit, came to me, to my great pleasure, from Mr. Gerald Loder. How many gardens have I seen with miserable tufts of the male form of this plant, and wondered how anyone should ever grow such a poor scrubby thing. On the other hand the female plant bears the most beautiful fruits one could wish for among winter berries. It is found more on the coast and in chalky districts in a fertile state, and hence, generally, gardens in the country do not show it in fruit. I am very glad to have it and am cutting up every bit I can of the female plant and putting it in the Heath garden. I think it is wild in what are called the undercliffs of some of the counties near the sea. In any case a nurseryman should have no difficulty in getting a stock of this brilliant native shrub. The plants came originally from near the Sussex coast and evidently are happy on the chalky soil.—W.

Potatoes.—An ominous sign of the times, says the *Daily Telegraph*, is the steady rise in the price of Potatoes. During the last fortnight the value of Potatoes has risen about 15s. a ton wholesale. To the consumer who calculates by the pound this may not seem much, but should it continue, the effect will certainly be felt throughout the length and breadth of the land. The wholesale price now ranges from 5s. to 7s. per cwt. in London, which means that the lowest possible figure at which retailers can serve the public is 3 lb. for 2d. As a matter of fact, 1d. per lb. is the universal price in most parts of

London and the suburbs. Reports to hand from Scotland indicate a shortage in the available quantity. Apparently there is plenty of Potatoes in Ireland, but facilities of transport are lacking. There is a general opinion amongst dealers that Potatoes will be dearer as the season advances. Owing to bad weather practically nothing has been planted, and the new crop will be very late.

Galanthus Atkinsi.—This Snowdrop, a form of *G. Imperati*, has handsome, shapely flowers of great purity. In the form of its flowers it is much superior to what is known as Backhouse's variety of *G. Imperati*, which has been grown by some as *G. Atkinsi*. The true *G. Imperati Atkinsi* is not so tall as Backhouse's variety, but is more erect in habit, and the flowers are perfect, whereas those of Backhouse's variety are not so shapely and frequently produce an additional segment, which gives the flowers a singular appearance when open. The true *G. Atkinsi*, which probably came from the garden of the late Mr. Atkins at Painswick, was sent out by Messrs. Barr and Sons as long ago as 1875. Its price then was half-a-crown per bulb, and the only trade purchaser at that time was the late Mr. Wheeler, of Warminster. As this Snowdrop died out with Messrs. Barr in their nursery at Tooting it was fortunate that Mr. Wheeler secured it, as it grew very freely with him at Warminster. Backhouse's variety was sent out by Messrs. Backhouse, of York, in 1877. Neither of these Snowdrops is at all plentiful, although apparently doing quite well in light soils. Backhouse's variety is always earlier with me than *Atkinsi*, although they are growing within 3 feet of each other. *Atkinsi* ranks with *Melvillei* as among the finest of our Snowdrops, and I find that it is more amenable to cultivation with me than *G. Imperati* imported from Italy.—S. ARNOTT.

Native plants.—I have often thought that if I had the space, and circumstances permitted, I would devote a certain portion of the available area to British trees, shrubs, and plants exclusively; not a single thing of exotic origin should enter there. I would plant the Sloe, the Bullace, the Hawthorn, the Dogwood, the wild Euonymus, the Gorse, the Broom, the Butcher's Broom, not forgetting that finest of all evergreens the Holly, but not the variegated forms, which would be out of place. I would use abundantly the Bluebell, the common Primrose, the Wood Anemone, and any other interesting plants of British origin, such as the field Scabious, *Potentilla Anserina*, Foxgloves, the Centaury, the Heather, and other native Heaths. It is only in this way that the true worth of British plants, trees, and shrubs can be realised. Is there anything finer than the Hawthorn when it comes into tree-form and happens—which is seldom—to have ample space. It then forms a low, spreading tree, lovely when in bloom, and quite as good in its second phase when loaded with berries. I have seen the Bullace on a Surrey common 12 feet high smothered with bloom and loaded with fruit and I know of Hollies 15 feet high with branches sweeping the ground. The Dogwood, when it has a fair chance, is very ornamental when in fruit. Our native shrubs, which formerly grew in the woodland and free, open spaces, have found their last refuge in old hedgerows, where they have to suffer periodical mutilation. Let them enjoy natural conditions and they surpass in beauty and effectiveness many of those things which are cherished simply because they come from foreign lands.—J. CORNHILL.

FRUIT.

THE BEST LATE APPLES.

I THINK "F. B." (page 138) is quite right in the conclusion drawn from his investigation as to the merits of late Apples alike as to scarcity of varieties and the two most worthy to follow in the wake of Cox's and Ribston. Where they can be satisfactorily grown one could hardly have two better sorts than D'Arcy Spice and Claygate Pearmain. The Apple known as The Spice (D'Arcy Spice), from the place whence it emanated, and Spring Ribston is not altogether an attractive fruit in appearance, although quite as much so, perhaps, as one or two more first-rate kinds, notably Cornish Gilliflower, but of really excellent quality. It takes a long time to develop into even a fair sized standard, being naturally of slow growth, but once established it is a very fair cropper, and I have also seen it satisfactory both in bush and cordon form. I have on more than one occasion strongly advocated the claims of Claygate Pearmain in *GARDENING ILLUSTRATED*, and always look on it as one of the best of the late Apples, but it seems to want a rather stronger soil than most to have it at its best, a natural sequence, perhaps, when one considers that the original tree is said to have been found in a garden at Claygate, in Surrey, a village of deep clay deposits and brick and tile-making industries. It is rather quicker and stronger in growth than The Spice, but only comparatively, and would be described as somewhat slow in growth and slender in habit. It is a good and consistent cropper when established, but the fruit spots rather badly in some districts if preventive measures are not taken. With respect to its partiality for a rather heavy soil I think this is a characteristic it shares with most of the Pearmain family. I have never, for instance, seen or tasted the old Winter Pearmain so good as in the Weald of Sussex. The best of the small late Apples is Wyken Pippin, and a tree or two might be included whether the plant is in standard, bush, or cordon form, as in either it comes quickly into bearing and is a consistent cropper. Although of small size it is much better in quality than sorts often recommended as good late kinds.

Hardwick.

E. B. S.

Cropping Vines.—Some growers are inclined to crop their Vines more heavily than usual this season. In every case it would be unwise to leave more bunches on the Vines at the final thinning out than each one can properly mature. If the Vines, especially young ones, are over-cropped, it takes several years' careful treatment to bring them to a normal condition again. Experienced cultivators know how to treat their Vines, but many amateurs err on the side of over-cropping. Young canes planted this winter or spring should not be allowed to bear any fruit during the coming summer. Older Vines that are in a bad state of health, and deficient as regards root-action, should not be cropped. Strong young Vines planted a year ago and duly cut back may bear one, or even two, bunches, according to the strength of the Vines and the size of the bunch. Established Vines that have filled the roof-space may be safely cropped to the extent of from 1½ lb. to 2 lb. per foot run of main rod. Then the berries will be full sized and colour satisfactorily. Over-cropping always has a bad effect on the colour of the Grapes and future crops. As

fire-heat may be restricted make good use of all available sun-heat, especially during the early stages of growth.—BOURNE VALE.

GOOSEBERRY RED CHAMPAGNE.

This is quite distinct from the variety known in Scotland as Ironmonger, in which the fruit is rounder and of a darker red, the habit spreading and not erect as in the Red Champagne. This erect growth we would gladly see more in evidence in the Gooseberry. The berries, so well shown in the illustration we give to-day, belong to the rough or hairy section, the skin rather thick, light red, the flavour very rich. There are, in addition to the Red Champagne, white and yellow forms. To have these small, richly-flavoured Gooseberries in perfection we find the best way to grow them is

cooked and are of a very bright red colour. I grew the variety for many years. It was raised by Messrs. R. Smith and Son, of the St. John's Nursery, Worcester, and owing to its medium height was a grand garden variety. As a cooking or preserving Raspberry none of the newer kinds approaches it.—F. K.

INJURY TO PEACH SHOOTS.

Will you kindly inform me what is the cause of the disease on the young shoot of Peach-tree enclosed? The tree is a young one, and was perfectly healthy until now. I should be glad to know if there is a remedy, and, if so, what it is. I may mention that the same has shown itself on a young Lime-tree in a quite remote part of the gardens here, but nowhere else, and the trees are quite 300 yards or 400 yards apart, with a hill between.—Mrs. M., Henley-on-Thames.

[The injury the Peach shoot has sustained is not due to disease, but appears to have been caused either by frost or as a result

This usually has the effect of putting an end to the further production of strong growth and in promoting the rapid increase of fibrous roots, without which well-ripened, fruitful wood may in vain be looked for. The remedy, therefore, in your case is at once to open out a trench some 4 feet or 5 feet distant from the tree, and to carefully search for roots from that point to within 3 feet of the stem. Carefully save all those of a fibrous nature and keep them in a moist condition till they can be replanted. All strong, thong-like roots met with (it is to these that gross-habited wood is due) should be shortened back to within 3 feet or 4 feet of the stem, doing this with a sharp knife, making the cut in a sloping direction, or to look outwards. Then lay the roots out afresh, place them in a nearly horizontal position, put some fibrous loam, if you can spare it, over them, and mix a fairly liberal quantity of old lime rubbish with the soil if none was added to the compost or staple when the tree was planted. Before finally filling in, settle the soil about the roots with a good watering; allow an hour to elapse for it to drain away, when the finishing touch can be given.]

NOTES AND REPLIES.

Apple-trees.—Recently, when pruning some young standard trees, I was impressed with the care needed in the removal of shoots. In one tree the major portion of the young shoots had fruit buds at the tops. After removing all crowded inside growths I left the others full length, and now there is a prospect of a fair crop. In my young days I was taught that these shoots must be reduced to make them produce fruiting spurs. Some other trees in the same plantation had not a bloom-bud on the young growths. Apple Peasgood's Nonsuch had most on the young shoots. When a young tree is well established and making good firm wood the best way is to let the shoots remain their full length and there will be no fear as to their making fruit-buds. I have seen shoots 2 feet long studded with fruit-buds. Hard pruning causes waste of energy and loss of crop.—J. CROOK.

Strawberry Fillbasket.—For many years the Strawberry I grew for preserving was the well-known Vicomtesse or Garibaldi. Of late years Fillbasket did such good service that it was grown largely for preserving and was all one could wish for. The Vicomtesse is earlier than Fillbasket, and at times I have, in a late spring, had the blossom injured by frost. Fillbasket flowers much later and gives enormous crops; indeed, I think this variety the heaviest cropper I know. The fruits are bright red, of excellent flavour, and make a splendid preserve. In a poor soil the plants made few runners. I did not allow the plants to remain more than three years in one place. Though in the third year the crop was heavy the berries were very small, hence the advantage of renewal as advised every third year. This is one of the Messrs. Laxton's best introductions.—W. F.

Striking Grape Vines (Amateur).—Strike your Grape Vine from single eyes and well-ripened wood. Cut the piece of wood to, say, 2 inches to 3 inches in length, half that distance each side of the bud, and pare away quite a third of the wood under the bud—that is, remove all bark and make a flat surface on the under part of the eye. Plant in good loam, and in a 3-inch pot. Make the soil very firm, and have the bud or eye just above the surface, the other part being covered—that is, the wood only, the bud being visible. Place in heat of 60 degs., which is none too much, and, if possible, give a little bottom-heat at the start. Damp overhead frequently, but do not give much moisture. Keep close, and in inserting the eyes place a little sharp sand under the bud.

Part of a fruiting branch of Gooseberry Red Champagne.

as flat-trained or cordon bushes. In addition to the three forms of Champagne just mentioned, the following are also good, and have the same erect habit of growth—viz., Langley Gage and Whitesmith, white; Green Gascoigne and Pitmaston Green Gage, Sulphur and Broom Girl, yellow.

Raspberry Semper Fidelis.—It may be thought unnecessary to grow Raspberries for preserving, but the variety in question was so distinct from others for this purpose that it met with a ready sale in the Midlands and was a great favourite in the Birmingham market. With the introduction of numerous new varieties I fear Semper Fidelis has been neglected, as I note it is not now catalogued by our leading fruit growers. I do not know of any Raspberry with such a distinct sub-acid flavour and excellent colour when cooked. The berries mostly remain whole when

of its having come into contact with unpainted galvanised wire. Judging by the grossness and unripe condition of the wood we incline to the belief that frost is the cause of the trouble, for the simple reason that under ordinary conditions young wood in a Peach-tree, if immature at the close of autumn, suffers in precisely the same manner as has the specimen shoot sent should severe weather be encountered afterwards, and the more soft and sappy the wood the greater the amount of injury sustained. To get the wood thoroughly ripened by the "fall of the leaf" is one of the chief aims of the Peach grower. To accomplish this the root system is as far as possible kept under control, or in other words the roots are prevented from either getting down into the subsoil or out of bounds by a periodical lifting and cutting back of the strongest, and by laying them out afresh in a nearly level position in the border.

ROSES.

ROSE PRUNING.

RAMBLERS, Noisettes, Hybrid Chinas, Teas, Bourbons, and Hybrid Perpetuals trained on the retaining walls of terrace steps, and over part of the masonry surmounting the latter, have been pruned according to their requirements and recorded. The latter is carried out in as informal a manner as circumstances allow. Dorothy Perkins is invaluable for this purpose, and the same with regard to that fine old Rose, Souvenir de la Malmaison. Gruss an Teplitz is a splendid variety for mingling with the last named, and is also very effective grown by itself in this way. Boule de Neige is another variety which gives excellent results when the last named is grown in combination with it. Laurette Messimy, Duke of York, and W. A. Richardson are also very fine as used for the clothing of the wing walls of a balcony, with the old Monthly China, Bardou Job, and Mme. A. Carrière on the piers. The young wood on the foregoing has sustained but little injury from recent severe frosts.

STANDARD ROSES.—These have been pruned, re-staked, and tied anew where necessary. Hybrid Teas and Bourbons have, in consequence of the wood having been damaged by frost, had to be cut back more severely than usual. Hybrid Perpetuals have had the heads well thinned and the young wood spurred back to three and four buds. The most annoying thing in connection with Roses grown on this principle is the tendency they have, as they become aged, to die off when spring opens. It is therefore necessary to have a reserve from which to draw upon in case of emergency. Unless the season is too far advanced they can be lifted and transplanted successfully in spring. Some Hybrid Perpetuals struck from cuttings, and reduced to a single growth, the latter being tipped at a height of 4½ feet, were employed two or three years since to fill some vacancies caused by death, and through the removal of others to another part of the gardens. The buds, with the exception of three nearest the tip, were rubbed out. These produced good stout shoots which flowered well, and which formed the foundation of the present heads. Since then the stems have thickened and are surmounted with good-sized heads which bloom well. So far they look very healthy.

BUSH ROSES.—A number of beds filled with Hybrid Perpetuals and Chinas, dwarf Polyantha, Provence, Moss, and other varieties has also had attention. The beds will be dressed with a suitable fertiliser, as manure cannot be spared, which will be lightly pointed in. The pruning of Teas and their hybrids will be deferred till the end of the month or early in April.

WEeping ROSES.—All the pruning required in this case is the cutting out of the weak wood and the tipping of the strong pendent shoots. Although there are several varieties of different types of Roses which are charming when grown on tall stems, so that the strong flowering shoots hang downwards, there are none more dainty in appearance and lasting in regard to the duration of their flowers than the Wichuraiana hybrid, Lady Godiva.

ROSE ARCHES.—The tipping of the long shoots and the cutting out where necessary of the weaker wood having had to be postponed through inclement weather, have now been attended to and the growths lightly fastened here and there to the wirework of the arches, or so that the flowers when open will be displayed to the best advantage. G. P. K.

GARDEN FOOD.

ENGLISH MELONS A MISTAKE?

I SEE a letter in the *Gardeners' Chronicle* from H. E. Durham praising the French Melons as worthy of our attention when grown in cool frames, pits, etc. One of the most curious facts is that we have in England poor kinds of Melon, which have always seemed to me to have an oily, poor, flavour, and by many people rarely eatable. In certain countries Melons wholly superior in flavour are grown as in North Africa, where the great oval Melon has a flavour of the finest Pineapple, and so, too, in America, where the field Melon is better than ours. The Melons grown in Spain and which often come to us in autumn are also good in flavour, but, having been gathered before they are ripe, are not to be judged of fairly. In the north of France and as far down as Orleans well-flavoured Melons of the Canteloupe kinds are grown, and often eaten with salt and pepper. They differ wholly in flavour from the others we know of, and are, I think, more wholesome and better. I always thought the slight difference between that country and ours would make it difficult to grow these Melons, but the writer referred to says he gets over the difficulty by means of a cold frame or a pit, and I am going to try the same, as that race of Melons would be a great addition to our tables. W.

NOTES AND REPLIES.

A useful salad Onion—Paris Silver Skin.

By many the Onion would be found fault with for salad, while others consider it an agreeable addition. The variety named I prefer to the Chives or the coarser Onions often used. There are now several varieties of the small White Queen type, such as the Improved Queen and others, all excellent for the above purpose. The last named may be liked on account of its size, as it is smaller than the Paris Silver Skin, but as regards size it is not necessary to allow the bulbs to grow too large, or the tops to age and lose the mild flavour liked in a salad. Very few persons sow what are termed salad Onions, but depend upon the ordinary sowing in the open. For years I have sown the Silver Queen in boxes in January and February for salads. Grown thus it is excellent. It is an easy matter to sow in this way for an early supply, and to make several sowings during the season in the open ground to keep up a succession. Those who have grown this type of Onion know how quickly it ripens. If sown thinly, small, shapely bulbs from 1 inch to 2 inches in diameter may be had in a few weeks. Sown, say, every month from March till August, it makes a splendid addition to the summer salads, the delicate flavour making it much more suitable than the ordinary varieties. There are no better Onions than these small, silver-skinned varieties for pickling, owing to their size, mild flavour, and colour.—F. K.

Seakale.—Well grown, blanched, and served this is one of our most delicious vegetables. Fortunately its cultivation does not present any great difficulty. The essential point is to select a plot of good ground exposed to the sun. The young sets are prepared from the roots of the old plants lifted for forcing. I select as far as possible roots ½ inch in thickness and about 5 inches in length, pointing the end which is to go into the soil. They are then tied into small bundles, placed in boxes with a little moist sand among them. If placed in a cool shed these keep per-

fectly until required. In March I put them out in rows 2 feet 6 inches apart, the plants in the rows 18 inches apart, leaving the crown slightly below the surface, and when growth commences thinning out the shoots to one. Keep the hoe plied freely among the plants during their growing season, and endeavour to build up strong crowns. On dry soils frequent watering is necessary. From November onwards these crowns should be ready for blanching, which may be carried out in various ways. For the earliest supplies I lift the crowns and place them (after removing all side roots) in deep boxes, which are stood in a dark, gently-heated shed. The heads obtained in this way are inferior to those obtained by placing large pots over the plants where they have grown, covering the pots with newly-gathered leaves, packed in tightly to exclude light and air. This old-fashioned method gives magnificent, succulent heads, weighing 1½ lbs., without the flower-stalk showing. When required for late use a heap of ashes is placed over each crown.—E. M.

Apple Dr. Harvey.—I have grown this for many years and consider it has no equal among Apples of its class and period of use. It remains in good condition till about the end of March. The fruit when cooked is of good flavour and very sweet. The colour is a fine yellow, and it appears quite proof against that troublesome disease, black spot. The tree is proof against the American blight and has never once developed even the faintest trace of the blight. To anyone who knows the heart-breaking labour and loss of time involved in cleansing and keeping clean an infected orchard this alone will surely be a powerful recommendation. The only fault of this variety is a tendency in strong, rich soils to make a good deal of small wood. This tendency, however, is easily checked by slight root-pruning, and this treatment, if combined with judicious manuring, will result in heavy and regular crops of magnificent fruit.—JOHN SCUDAMORE, *Ditchingham Rectory.*

Seakale forced or not forced.—I have lately enjoyed some Seakale which had been gently forced by leaves on the spot where it grew, and must say the flavour was much better than it is when the roots are forced in a house. Succulence and flavour are both much better if the shoots are advanced in a natural way, and, if possible, without manure. The green Seakale, as it comes out of the sand, is also well worth eating. The forced Kale one often sees at tables is weak and inferior.—W.

The Dandelion as a salad.—When well blanched and mixed with Celery and Endive in the salad-bowl this forms an excellent salad, and one which is very wholesome. The improved broad-leaved Dandelion is far better than the old form of this common weed. Seed sown now will furnish strong roots for the following winter's forcing, and a dozen roots put into the Mushroom-house weekly will furnish a good cutting every day. Some palates may object to the bitter flavour of the Dandelion, but others, again, think this its best quality.

Mixed dry fruits.—The above make a useful and palatable change from the usual run of raw or cooked fruits. Quite a good variety is present in the mixture: Apples, Peas, Apricots, Prunes, generally Figs, but owing to the difficulty in obtaining them they are not found in every mixture. There is sometimes another fruit present that I am not sure of—the small core is usually left in it and the kernels resemble those of the Apple, while the flavour is pleasantly brisk. To cook these there is no need to add any sugar. Stand the fruits in warm water for a few hours, and then cook slowly in the oven. The addition of custard is a matter of taste.—C. T.

TREES AND SHRUBS.

PINK PEARL AND OTHER CHOICE RHODODENDRONS.

RHODODENDRON Pink Pearl was a decided gain to our gardens, for in it we have a variety combining the large flowers of a species like *R. Griffithianum* with the shapely and compact truss of the *R. catawbiense* hybrids. Its parentage does not appear to be generally known, although it is said to claim *Cynthia* as one parent. From its general appearance, however, it would appear that there has been some influence of *R. Griffithianum* at work. Many of the hybrids which contain blood of that species have loose trusses and very large flowers, and they are not very hardy, as may be instanced by the very beautiful sorts one sees in Cornwall,

Gardens, Kew, but in the North of England and in Scotland.

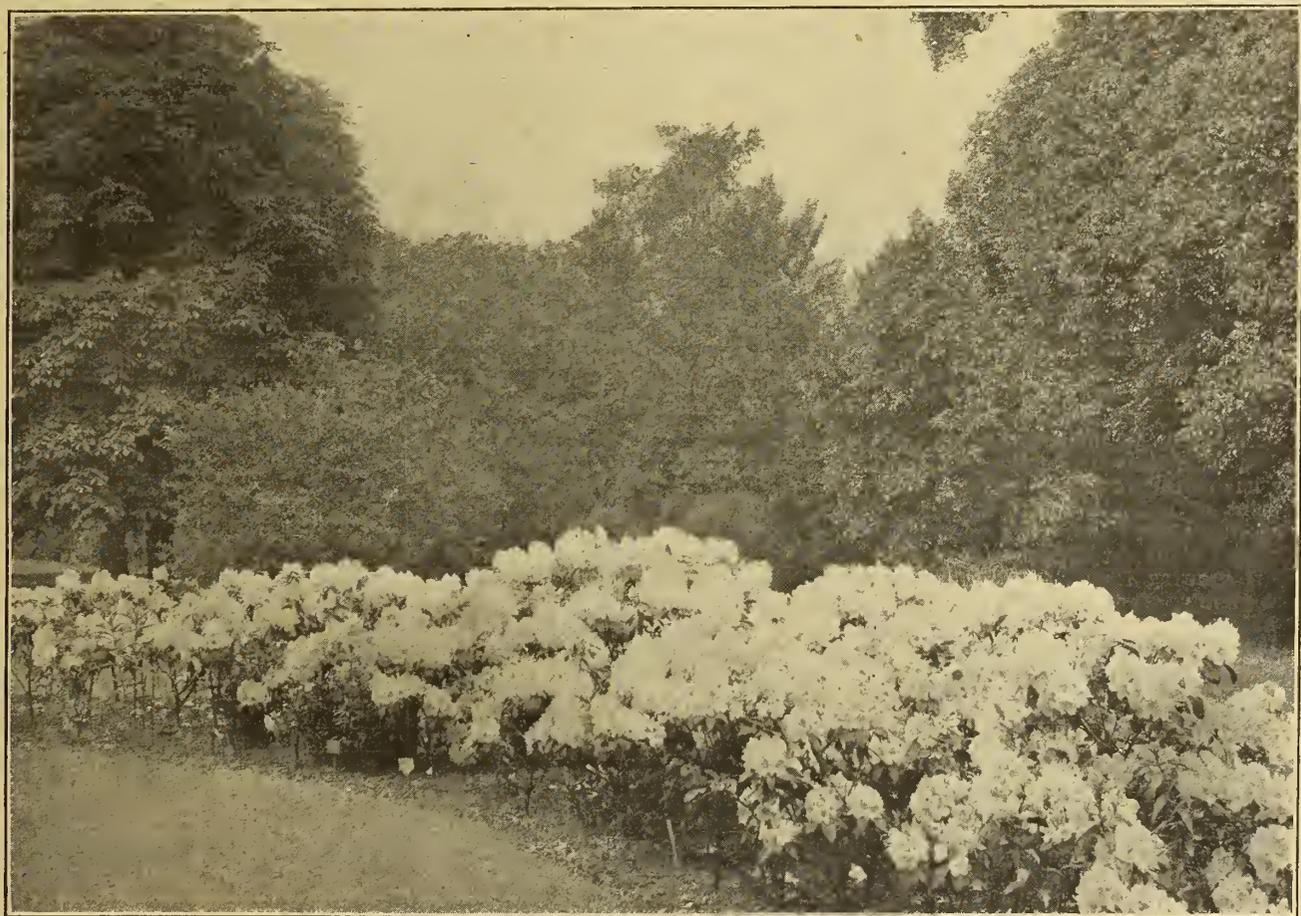

There are other kinds with large flowers and large, shapely trusses, which can be grown with Pink Pearl, the majority of them having appeared since the introduction of that variety. White Pearl, a sport from Pink Pearl, has large trusses of white, pink-flushed flowers, but is not so beautiful as the older plant. It is much like *R. Gauntletti* in appearance. Gomer Waterer bears immense heads of large, white, rose-flushed flowers. It is of sturdy, compact habit, with fine dark-green leaves. Juliana bears a resemblance to Pink Pearl in size of truss and flowers, but the bright pink blossoms have fringed or waved margins. Alice, one of the newest varieties, is recognised by its pink flowers being deeper in shade than those of Pink Pearl. Mrs. E. C. Stirling pro-

under the name of Dawn being specially remarkable for its large flowers and trusses.

Raisers of new, large-flowered kinds would do well to keep hardiness and late-flowering in view, for though most kinds can be grown in the milder counties, those which are tender, either in winter or spring, by reason of early growth and flowering, must necessarily have but a limited sphere of usefulness. It is always desirable to obtain plants on their own roots whenever possible, for grafted plants are liable to injury from suckers appearing from the stock and overwhelming the scion. D.

NOTES AND REPLIES.

Trees in storms.—In the storm of March 24th, 1895, the wind blew first from the south-east, veered round to the south

A group of Rhododendron Pink Pearl in the Royal Gardens, Kew.

Devon, S. Wales, and other places where the climatic conditions are similar. There may be seen such kinds as Gill's Triumph, with rich, bright red, almost scarlet, flowers, of great size and substance; Glory of Penjerrick, with as fine flowers of a darker shade; Beauty of Tremough, with pink-flushed blossoms; Lilian Fox, with large, shapely trusses of blood-red blossoms; cornubiense, only slightly inferior to the last named; Gauntletti, a beautiful pale pink with trusses sometimes nearly 1 foot high and 8 inches wide. These do not give good results in the immediate vicinity of London, although several of them thrive a few miles out on the higher land of Surrey, Kent, and Sussex. Pink Pearl, on the other hand, is much hardier, and gives excellent results not only about London, as may be seen by the accompanying illustration of a bed in the Royal Botanic

duces large pyramidal heads of white flowers which are flushed with pink. Strategist is a rich pink with large flowers and compact trusses. George Hardy, with white flowers, is a handsome variety, as also is the old, but not well known, *R. Manglesi*, a particularly desirable kind by reason of its erect and compact inflorescences of large white flowers. This variety was raised by the late Mr. Mangles, who also gave us many desirable kinds. A beautiful red-flowered hybrid raised at Kew has been called The King, a first cross from *R. Griffithianum*, and presumably less hardy than Pink Pearl. Sir Edmund Loder has raised many new kinds, some with very large trusses of flowers. All that he has raised are hardy with him near Horsham. Several have been exhibited by him of late years at the fortnightly meetings of the Royal Horticultural Society, one shown

and west, and finally to the north-west. There was no snow, and only a little rain fell near the end. On March 28, 1916, the wind blew at first nearly due east, and finally from the north; heavy snow fell continuously throughout the 26 hours it lasted, and the freezing of the snow on the branches of the trees assisted much in their destruction. In both years the gales had been preceded by a long spell of wet weather. In 1895 the conifers which suffered were *Cedrus Libani*, *Cupressus macrocarpa*, *Picea pectinata*, *P. lasiocarpa*, *P. bracteata*, *P. Pinsapo*, *P. amabilis*, *P. nobilis*, *P. ephalonia magna*, and the *Larix*. In 1916 the few *Cupressus macrocarpa* that were left have all been blown down; the Larches have nearly all gone, and also *Pinus Strobus*, *Abies excelsa*, and *Cupressus Lawsoniana*, which had stood out the ordeal of 1895. In both gales the Conifers that have weathered them are:

Sequoia gigantea (out of more than 100 specimens here both in sheltered and exposed situations not one has been blown down), *Sequoia sempervirens*, *Thuja gigantea*, *Libocedrus decurrens*, *Pinus ponderosa*, *P. austriaca*, *P. Laricio*, *P. Jeffreyi*, *P. Pinaster*, *P. Sabiniana*, *P. muricata*, *P. macrocarpa*, *P. sylvestris*, and *Cupressus sempervirens*. Specimens remain of *Abies Douglasi*, *Picea grandis*, and *P. Nordmanniana*. Of the hard-wooded trees, Elms and Chestnuts have suffered most severely in both gales. Sycamores and Beech have survived. Yew, Holly, Box, and Laurel have been much damaged by the storm of last Tuesday.—HUNTLY, *Orton Hall, Peterborough, in Times.*

INDOOR PLANTS.

WATERING POT PLANTS.

THE question is often asked, "How often ought I to water my plants?" Though pot plants should be examined periodically—usually once a day—atmospheric and other factors vary so much that no fixed rule can be laid down. Most plants in a growing condition require water when the soil is approaching dryness. To an experienced gardener this condition is usually indicated by the appearance of the surface, combined with his knowledge of the plant, the soil in which it is potted, and the drainage. Novices are often recommended to tap the side of the pot with the knuckles, a clear ringing sound being emitted if the ball of earth is dry, or the reverse if wet. It is a useful but not a perfect test, because, although a pot plant is always dry when the pot rings, the plant should have been watered just before that stage is reached. If the ball of earth has shrunk from the sides of the pot some injury has already occurred to the roots. The point of a healthy root is thickly covered with short hairs. Turn a young, soft-wooded plant out of its pot, and the roots, if growing freely, will show this feature plainly. It is principally through these hairs that water and, with it, nutriment in solution are taken up. They are extremely delicate and soon perish under any unfavourable conditions, such as stagnant or insufficient moisture. New root hairs quickly form again if the cause is merely temporary, but a check is given to the plant, which all good cultivators strive to avoid. Such a check is often apparent in the cessation of growth at the points of the shoots or the appearance of yellow leaves at their base. When water is applied, enough should be given to moisten the soil throughout. This is comparatively easy if the plant has been potted correctly, viz., if the soil has received an equal pressure throughout and a suitable space and no more has been left between the soil and the rim to hold the water. The actual measurement varies, of course, according to the size of the pot, but the proportion is always the same—about one-tenth of its height. A greater space causes so heavy a saturation that the soil may become sodden, while less will in most cases be insufficient, and the plant suffers in consequence.

RAIN-WATER is the best, but ordinary service or spring water can be rendered quite suitable by exposing it for twenty-four hours in the open air. Water should always be raised to the same temperature as that in which the plants are growing before it is applied to their roots. Drainage is not absolutely necessary if watering is carefully carried out, but in most cases well-drained pots are as necessary to the plants as a safety-valve is to an engine. Good drainage often prevents over-watering from being fatal. Hard-wooded plants,

such as Heaths and Azaleas, are particularly sensitive. Plants seldom remain long in a healthy condition when the pots are exposed either to a sharp draught or to the full rays of the sun, the constant watering necessary washing much of the nutriment out of the soil. A plant droops its leaves because moisture is being evaporated from them faster than it can be supplied. Flaggings is by no means an infallible sign that the soil is dry; often, indeed, that it is too wet, and that the points of the roots have decayed and can no longer absorb the moisture with which they have been surfeited. During summer the afternoon and evening are the most suitable times for watering, as the soil remains moist during the night and the plant can absorb a good store against the coming day. In winter the morning is better, the superfluous moisture being then carried off before the house or frame is closed for the night or a low temperature occurs. Plants that it is desired to repot should always be watered previously and allowed to drain, so that the soil is moist, but not sticky.

Should plants be watered at once after repotting? Much depends on the season of the year, the condition of the ball of earth, if any, surrounding the roots, and the frame, house, or window in which they are to be placed. In summer a light watering may be given with advantage, but the cultivator should aim at keeping the plant moist by shading, reducing ventilation, and spraying the foliage, anything, in fact, to prevent evaporation, rather than by saturating the soil about its roots. In winter, if the soil used is in a fairly moist condition, no water will be needed for several days, and then only sufficient to reach the drainage. Many seeds never germinate at all in a heavily-saturated soil, and cuttings decay. The advice as to light watering and the subsequent prevention of evaporation given above applies even more strongly in these cases. When saucers are placed beneath plants to catch the water which drains away, the plants should not be allowed to stand in the water, which should be emptied out and two little pieces of wood placed in the saucer to keep the pot above the water, especially in winter or in the case of sensitive-rooted plants. Persons who are fond of plants will soon learn when they want water, and achieve success where others fail, by anticipating and supplying their wants. J. COMBER.

Nymans.

GLOXINIAS GROWN COOL.

WHERE Gloxinias are grown from seed in order to obtain good flowering plants the first season, a considerable amount of heat during their earlier stages is necessary. Nearly all writers on Gloxinias refer to them as requiring stove, or, at all events, intermediate-house temperature. Good Gloxinias can, however, be grown under much cooler conditions, as I have proved over and over again. In order to obtain the best results in this way the tubers of the preceding year should be laid in boxes of sandy soil, kept almost dry, and wintered in a temperature not lower than 15 degs. at night. This is about that of an ordinary greenhouse, in fact such a structure as tuberous-rooted Begonias will be quite safe in when dormant. Much the same treatment will suit these two classes of plants. By the middle of March, or thereabouts, the Gloxinias will be starting into growth, when they should be potted and placed on a stage in the warmest part of the greenhouse. They must be moderately watered, when, under the influence of the spring

rise in temperature and increased sunlight, they will soon start into growth. Tubers about the size of a penny are the most suitable for flowering in this way. The first potting should be into pots $3\frac{1}{2}$ inches to 4 inches in diameter, using a compost containing a liberal amount of good leaf-mould. When these pots are well filled with roots the plants should be shifted into those in which they are to flower. For this purpose 5-inch ones are very suitable, though a few of the strongest may be put into pots 6 inches in diameter. Given a good light position in the greenhouse, yet shaded from bright sunshine, the plants will make satisfactory progress, the growth being stout and sturdy. If a cold-frame is available the plants may, towards the end of May, be placed therein. Watering must be carefully done, and if the weather be cold the lights may be closed early so as to husband a little of the sun-heat. Grown in this way insect pests give but little trouble, but should thrips put in an appearance they may be readily destroyed by vaporising with nicotine. An occasional dose of liquid manure will be beneficial when the pots are well filled with roots, but care must be taken not to spill any on the foliage.

Plants treated thus are later in flowering than those grown under warmer conditions, and are therefore valuable in maintaining a succession, while the amateur with but a greenhouse and perhaps a frame or two is thereby enabled to grow them. Gloxinias grown in this way will flower well in July and August. Tubers suitable for this mode of treatment can be purchased when dormant at a very cheap rate. K. R. W.

NOTES AND REPLIES.

Greenhouse Acacias.—The well-known *Acacia dealbata* (the Mimosa of the florist shops) is too large to be accommodated in an ordinary greenhouse. There are, however, several that will flower freely in pots from 5 inches to 6 inches and upwards in diameter, and are of considerable value for greenhouse decoration. Among them are *Acacia platyptera*, whose blossoms, like little golden balls, are borne during the autumn and early winter months. *A. hastulata*, also known as *A. cordata*, does not bloom till the New Year, the straw-coloured blossoms being freely borne. A neat, bushy-growing species is *A. ovata* or *obliqua*, which flowers quite early in the year, and bears a profusion of bright, golden-yellow flowers. A species quite distinct from any other is *A. Drummondii*, whose pale-yellow flowers are borne in bottle-brush-like clusters. One that will attain a considerable size and yet can be flowered freely in a comparatively small state is *A. armata*, a sturdy-growing bush, with rich golden-coloured blossoms. Quite different from the others is *A. lineata*, a compact-growing kind, whose bright-yellow flowers are very numerous. All of the above may be readily grown in ordinary potting compost, such as a mixture of loam, peat, and sand. *A. platyptera* and *A. Drummondii* are benefited by a larger amount of peat than the others. These different Acacias can be placed out of doors during the summer months, under which conditions they will flower more freely at the appointed time.—K. R. W.

Begonia Gloire de Lorraine.—Cuttings from the base of this plant are now showing freely, and as soon as they reach 2 inches in length they are taken off, inserted in small pots of sandy soil, and placed in a propagating frame with a fairly moist atmosphere. Avoid striking cuttings made from last year's stems, for, though these may be got earlier, they keep on flowering, and get stunted in growth. Those of the right kind, taken off later, will soon overtake such as these, and make far more satisfactory plants.

OUTDOOR PLANTS.

CROCUS MARY VAN MARIS.

This is one of the half-dozen novelties sent out by Messrs. Van Maris, Hillegom, three years ago. It is a large and beautiful pure white flower, with a striking orange stigma, which is most effective when the blooms are fully expanded. I have found this lovely Crocus excellent for forcing in pans, simply plunging in leaves from the time the corms are planted until the flower-stems are about 1½ inches high, afterwards bringing gradually to the light. In this way all the bulbs bloom together. This variety is now (March 26th) flowering in the Grass, where its snowy whiteness is seen to advantage. E. M.

SOME USEFUL HARDY TUB PLANTS.

SEVERAL illustrations which have appeared lately in GARDENING ILLUSTRATED showing the nice effect produced by pot and tub plants in certain positions in the

ground beneath and around should be thoroughly moistened when the weather is dry with a fine rose daily before noon.

With regard to plants suitable for the purpose among the first chosen would be Funkias, the large, handsome foliage and showy flowers being somewhat unique in hardy things. *F. ovata* and *F. o. variegata* are two of the best. The Maiden's Wreath (*Francoa ramosa*) is not quite hardy, but there is nothing like it out of doors in the summer. Established plants throw a great quantity of tall, graceful spikes and associate well with other things. A mass of rich golden-yellow will be supplied by *Oenothera fruticosa Fraseri*, one of the best of the Sundrops. There is an impression that all these are decidedly short-lived in flower, but it is not so with the variety under consideration. Given good cultivation it will continue in bloom for several weeks, and not a few solitary flowers, but quite a nice display. The best of the forms of *Chrysanthemum maximum*, as Mrs. Bell and King Edward (the

When tubs have been well prepared for a start the plants should make good headway and will require little attention the first season, except in the way of careful watering and any staking and tying that may be necessary, but in after seasons will be benefited by a rich top-dressing before the young growth starts. If no rough shed of sufficient size is available it is as well to knock up a frame-work of uprights and cross-pieces to support a dressed cover under which the tubs can be placed through the winter, and if the weather is exceptionally severe a little dry bracken can be worked between them and shaken over the surface. E. B. S.

Hardwick.

AMONG THE HARDY FLOWERS.

PRIMULA ROSEA.—This dainty Himalayan Primrose has now come into flower, although the stems have not reached their full length. I know that it does best in a really moist place, such as by the side of a stream or pond, but it is not everyone who

Crocus Mary van Maris.

garden and in the immediate neighbourhood of the house, mostly in the way of semi-hardy and tender things, have led to the thought that there are several hardy plants that might be utilised for a similar purpose where tender things are not available. Good tubs for the purpose can be made by sawing old 18-gallon casks in half, the exteriors painted green or oak-stained as deemed advisable, and a pair of cheap handles provided for convenience in lifting. The percentage of holes bored in the bottom should be on the same lines as an ordinary flower-pot, and the drainage not too liberal, a couple of layers of crocks and a handful or two of coarse ashes being all that are necessary. A good compost to put on the drainage is ½ inch of dry cow-manure well broken up, and this, together with a little good leaf-mould, can also be incorporated with the potting soil, a good, fairly-holding loam in the proportion of one to five. The tubs should be raised slightly from the ground, and, if standing in positions fully exposed to sun and wind, woodwork, soil, and

one a little earlier than the other), will furnish material for a couple of tubs, and also last a long time in flower if care is taken that the foliage is kept free from the attacks of the leaf-boring maggot. A tub or two may be devoted to Phloxes, but a shady spot will have to be found for them, otherwise, in a hot summer, foliage and flowers will suffer. Good sorts are Frau Antoine Buchner (white), Selma (pink), Coquelicot (orange-scarlet), and Crepuscule (silver-mauve). Early-flowering Chrysanthemums are so well known for the purpose that it is only necessary to suggest the choice of sorts or colours that may be most appreciated. Not so well known for the purpose, but equally beautiful at about the same season, are the best of the Japanese Aneones, semi-double sorts like Lord Ardilaun (white), or of extra substance like Queen Charlotte (pink) are the most enduring. If any tubs can be spared for scented evergreen plants, *Choisya ternata*, the Munstead Lavender, and Rosemary are three interesting things to grow.

is fortunate enough to possess either of these. I find that loam and leaf-soil or peat, in equal proportions with some sand, are quite a good medium for this lovely Primula. It is true there is a little hardness about the colour, but that cannot be helped, and the best varieties I have seen are really very brilliant.

THE YELLOW CROCUS AND THE BIRDS.—It is curious how in some gardens the birds rarely, if ever, trouble the yellow Crocus, while in others they ruin the flowers, tearing them to pieces and apparently taking delight in wrecking the hopes of the gardener. In other places—my own among the number—they rarely do any harm. A well-informed ornithologist, who was also interested in plant life, once told me that he had formed the opinion that certain families (I use the word in its restricted sense) had acquired the habit of destroying the yellow Crocus, while others had not. That is to say, that there are certain families of the common sparrow, for example, which will destroy the Crocus, while others leave it quite unharmed. I

think this idea is a little far-fetched, although there may be some truth in it. Is it not a question of food or water? I have the greatest sympathy with those who see their Crocuses torn up, and I am glad that I have not to have recourse to the device of using threads above the flowers.

THE ORANGE DAISY.—I see this name given to *Erigeron aurantiacus*, which I admire very much, but which, with me, is very liable to die off. I believe this is due to the attacks of slugs in autumn and spring. I have been looking over some seedlings and find that they have been very badly cropped by the slugs. I have in some former seasons, though not to the same extent, had a similar trouble with the Alpine Starwort (*Aster alpinus*). It is very provoking to find that some plants have been so severely cropped by slugs that they are quite ruined. I believe that all such plants stand a much better chance of escape if they are top-dressed in early autumn.

LYCHNIS CHALCEDONICA.—When readers are thinking of ordering seeds of hardy perennials I would suggest that they might consider this. It is quite a showy border plant for summer bloom, and a group of seedlings, such as may be procured from a small packet of seeds, will give a sufficient number of plants to constitute an important feature in the border. It flowers generally from early July (sometimes earlier) well through August. It is about 3 feet high. The flowers are of a brilliant scarlet. Some folks prefer the double variety, but I do not consider it better than the single one.

SPIDERWORTS IN SPRING.—The quaint, old-fashioned Spiderwort, or *Tradescantia*, has two seasons of value in the garden. The summer one is universally recognised, as almost everybody admires the distinct look of the leaves and flowers, but it is not generally observed that it is a pretty plant in early spring when sending up its young growths in a nice garb of good colours, shades of purple and crimson.

AN AMATEUR OF HARDY FLOWERS.

FUCHSIAS IN THE FLOWER GARDEN.

Those who have a stock of old Fuchsias will find them very useful for the flower garden through the summer if there are a few vacant beds. Such beds might be partially carpeted with Tuffed Pansies, leaving the necessary spaces for the Fuchsias, which as either large, medium, or dwarf plants should have sufficient room to develop. It is as well to act on the principle of one bed one variety unless there are sorts of different heights very similar in colour, as, for instance, *Flocon de Neige* and *Alice Hoffmann* and *General Roberts* and *Display*, in which cases the two varieties can be used respectively in the centre and outer portions of the beds. Another bed may be set apart for *Sunray*, with its rich golden foliage, on a carpet of *Kingcup Pansy*. If the old plants have been stored away under a stage, an outhouse, or similar places, they should, after the necessary cutting back, soaking, etc., be allowed to break slowly and be grown along steadily without any attempt at forcing, and if put into a bit of fairly good soil when potted up from the ground will want little attention until planting time except pinching back any shoot likely to get too long, and occasional doses of weak manure-water when roots are pushing actively. In connection with Fuchsias it may be noted that there are places in most flower gardens where some of the varieties of *F. macrostemma* can be used to considerable advantage. *Riccartoni* is one of the best,

and a very nice effect is produced by associating this with small clumps of *Yucca filamentosa*, with some plants of the dwarf *Dunrobin Castle* towards the edge of the beds. Another variety of *F. macrostemma*—*gracilis variegata*—is very useful as an occasional dot plant on a carpet of purple Pansies. E. B. S.

Hardwick.

COLLEGE MEN AND LANDSCAPE GARDENING.

The Americans begin to snuffer from the work of pretended landscape gardeners, who think that work can be done without a gardener's training and without the full knowledge of trees and shrubs that anyone who has any claim to design gardens should possess. We find the following in the *American Gardener's Chronicle*:—

One of these novices was called in to make a plan for a small place of about 5 acres. After completion it was found that the plan could not be made to fit the ground, and, among other incongruities, it contained a rustic bridge. The designer had, however, neglected to specify where the water to flow under it was to come from as there never was any water, still or running, where the bridge was planned to be erected, the only water on the estate being that derived from a well 300 feet deep and the nearest stream was three miles away. In a city where the appointment is political, and therefore the holder need have no qualifications, the park superintendent asked to have a landscape gardener appointed as his assistant, and the job was given to a young man just out of college. One of the first attempts of the latter was to destroy a good lawn by cutting a large bed in the middle of it and "bedding out" in March some three hundred Easter Lilies in full bloom from a greenhouse. Three days were more than sufficient to bring them into a condition for the dump; *Astilbes* were put in their place, which required a less time for their destruction. As this lawn was partially surrounded by naturally arranged shrubbery the discord thereby created may be imagined, and it caused a deal of amusement in the city at the time, even among those who did not claim to have much knowledge of gardening, and many desired to know if that was the style of landscape gardening taught at college. This same man committed the vandalism of destroying some of the late Frederick Law Olmsted's classic work because it interfered with the view of the pedestal of a statue!

More recently the landscape work upon two new estates was given into the hands of a young college man. His plans proved him to be absolutely unacquainted with the merest elementary principles of art in the garden and that he had no knowledge whatever of horticulture. His planting plans called for huge thickets of shrubs all spaced exactly 18 inches apart; beds of *Rhododendrons* were in positions where they received all the sun at all seasons, and herbaceous perennials were quite unprovided for; perhaps he had never heard of them. College education may have some value, even if nothing more than that set forth by a prominent public man a few years ago, who stated that everyone who could should go to college if only to find out the uselessness of college education in the practical work of life.

NOTES AND REPLIES.

Campanula glomerata.—There are three varieties of *Campanula glomerata* which are worthy of cultivation, these being *C. g. acaulis*, *C. g. dahurica*, and *C. g. superba*. The first sort produces dense clusters of beautiful blue flowers from May to August. Its height is somewhat variable. My plants reached about 12 inches, but other gardeners tell me they only get their plants half this height. The second sort has flowers of a fine violet colour. The flowers are large and freely produced from June to August, and the plant reaches a height of about 2½ feet. The third sort (*superba*) is finer than either of the above, but still less often seen, because for some reason it has not come to the front. The flowers are much deeper in colour and borne on erect stems in July and August. The plant reaches a height of 12 inches to 18 inches and is remarkably free-flowering. —E. T. ELLIS, *Wetwood, Ecclesall, Sheffield*.

Oenothera Lamarckiana.—This (page 141) seeds so freely that it is liable to become a troublesome plant in the garden unless precautions are taken to remove a portion at least of the seed-pods before the seeds ripen. There is not much chance of its being lost from a garden where it has once been grown, as one or two plants will provide any quantity of self-sown seedlings to maintain the succession. Its great weakness from a garden point of view is that it is dowdy-looking in the morning and early afternoon. It is only in late afternoon that the flowers expand these lasting through the night. They are large and of a pleasing yellow, but have a rather peculiar butter-like odour. It is a true biennial.—S. A.

Scilla bifolia alba.—The flowers of this are not so large as those of some of the other varieties of *S. bifolia*, but make a nice contrast to the blue and pink varieties. The finest white form of *S. bifolia* I know is *White Queen*, a beautiful variety raised or selected by the late Mr. James Allen, of Shepton Mallet. The blooms are about twice the size of those of the others, and of good substance. A great deal might be done in the way of improving the white varieties of *S. bifolia* by raising seedlings.—S. ARNOTT.

Sweet Peas.—With advancing growth much more watering is now needful in the case of Sweet Peas. The stems ought not to be permitted to fall about over the pots, and small temporary supports of a twiggy nature should be afforded in good time. If under glass in cool house or cold frame the pots must be kept as near the light as possible. This prevents unnecessary drawing; and, further, to induce a robust and stocky growth, as much air as possible must be given on all suitable occasions.

Dog's Tooth Violet in Grass.—I am pleased to see that Mr. F. W. Gallop advocates planting *Dog's Tooth Violets* in Grass in his calendar for the "Midland Counties," on page 174. They are charming in Grass, and, as the foliage dies off early, they are not in the way in a lawn which is kept mown in summer. The varieties of the common *Dog's Tooth Violet* seem to be the best suited for the purpose, and colonies of this plant in irregular patches in the Grass are very beautiful.—S. ARNOTT.

Jeffersonia diphylla.—Those on the outlook for a plant which will succeed in a shady corner will find a suitable subject in the above. It flowers during late April, is about 8 inches in height, and produces freely pure white blooms, each almost an inch in diameter. Although it does best in peaty soil, yet I know that it grows quite well if well-rotted leaf-mould be substituted for peat. It may be increased by seeds, but good results follow division, this being best attended to in November or December.—KIRK.

Anemonopsis macrophylla.—As its name indicates, this resembles to some extent *Anemone japonica*. Its *Anemone*-like blooms are pure white with a tinge of violet, and are freely produced in late summer and autumn. *A. macrophylla* succeeds well if it is treated in all respects similarly to the Japanese *Anemone*, and, like it, may be increased by division or from root-cuttings.—SCOT.

VEGETABLES.

PROFITABLE VEGETABLES.

It may be advisable to dispense with a few things that would otherwise be grown in order to utilise all available ground for the most profitable things. These, besides Potatoes, will be Onions, Runner Beans, Spring Cabbage, and medium-height curled Kale, and to them might be added a dwarf Marrow Pea and green Haricot French Bean to be grown for harvesting and used occasionally as required through the winter months. I should also like to add Seakale. There is an impression that this occupies an undue area in proportion to the results obtained. On the contrary, a wealth of material can be obtained from a small piece of ground, given good cultivation. The ground should be manured and deeply dug or bastard-trenched, and sets put out about 9 inches apart and 18 inches between the rows, or, at any rate, sufficiently wide to allow for ridging up with some light material for blanching. When gathering the first crop care should be taken to avoid cutting below the crown. If this receives attention a nice after-growth follows, which, if small, is very tender and of delicate flavour. The planting should be an annual affair. The old plantations of Seakale yield a lot of material for cutting, but the blanching is a troublesome business unless one has pots and leaves or litter, whereas with the annual crowns in rows this is not required.

There are some vegetables which may safely be reckoned as profitable if intelligently treated. Cauliflower among the number. If three sowings are made of a small, quick variety respectively in February, late March, and mid-May, a nice succession is obtained and the ground can be soon cleared. This is much more profitable than growing Broccoli, which in some cases remains about ten months on the ground before the single head is obtained. A similar three-course sowing is the most profitable way to deal with Carrots, and if those from the last sowing in July are allowed to remain in the ground with a little protection in the way of Bracken or some similar material the roots can be pulled as required all through the winter. Of those things which are very acceptable but quickly over, as Spinach and Lettuce, the best way is to sow small quantities and often. The requirements of the household, whether on a large or small scale, can soon be noted, and measures taken accordingly. Spinach, however, is very seldom found in medium and small gardens, and does not seem very popular, this also applying to Parsnips and Jerusalem Artichokes. I always think this is specially unfortunate in the case of the last-named, because a number of tubers can be so easily grown, and that, too, in positions hardly suitable for other things. It is a nutritious vegetable that can be used satisfactorily in many different ways, but the cottager and small-holder will have nothing to do with it. E. B. S.

Hardwick.

NOTES AND REPLIES.

Early-sown Beetroot.—There is no difficulty in having good roots from last season's crops if cool storage is given, but at times there is a scarcity. There is a considerable demand for young roots for salad as soon as they can be had. Few vegetables force more readily than the Beet, if the term forcing can be employed, and it gives so little trouble. For many years I used to sow in March in 60-pots seed of a good Globe variety, taking care to sow only a few seeds round the outside of the pots. When it was seen which were

the strongest they were thinned to three plants and grown near the glass in cold frames. Grown thus the plants were of a nice size for planting out the first or second week in April, care being taken not to break the ball. The seedlings do well planted out at the foot of a warm wall in good soil, and may be placed fairly close together. It is surprising how quickly they are fit for use if given moisture in a dry spring. The roots, though not large, are much liked in May and June for the salad-bowl. I have at times sown in boxes thinly and transplanted when the seedlings were of a fair size, but care has to be taken that the tap root is not broken at the lifting.—E. R.

Pea World's Record.—I first grew this variety in 1911, a season none too favourable, as we had very dry, hot weather quite early in the season, but it did well. It is an early Pea, but I do not advise sowing it too soon unless the land is well drained. For June and early July gathering it is splendid, and, sown for that purpose in March and April, there will be a heavy crop. The pods, borne mostly in pairs, are quite large for an early Pea, having eight to ten Peas in each. The quality is so good that I am sure those who have grown it will not omit doing so again. The pods are long, dark green, and the haulm vigorous for an early variety. What makes it more valuable is its heavy cropping. Being a medium grower—3 feet—it can be grown somewhat closer, thus making it an ideal variety for gardens limited in size. I have had it fit for the table in thirteen weeks from date of sowing.—W. F. K.

Tomatoes.—If these are required for planting out-of-doors a sowing should be made at once. Sow the seeds thinly in clean, well-drained pots or pans, using a compost of loam, leaf-mould, and sand. Do not make the soil too firm in the pots, cover the seeds lightly with fine soil, and place in a warm house, or put where there is a little bottom-heat. The chief aim should be to raise the plants in medium warmth, and keep them sturdy yet steadily growing throughout. As it is unsafe to plant Tomatoes out until the end of May, or early in June, it is obvious that strong plants must be available at that time, as our summers are generally short. Well-grown plants, if attended to, will give good crops of fruit in the open in sunny seasons. Sunrise, though a tall grower, does well outside, so do also Sutton's Open Air and Up-to-Date.

Greening Potatoes.—At one time it was quite customary for the older school of Scottish gardeners to "green" the tubers before they had completed their growth. The method adopted was to draw the soil from the tubers in the drills when they were rather more than half-grown, and when they were thoroughly greened they were lifted and stored. Actual experience shows that the crop is heavier from immature greened tubers than from fully ripened sets. This raises an interesting question. Would immature seeds of other things—Peas, for example—give similar results? It might be rather useful to experiment.—W. McG.

Early Peas.—Adverse weather conditions have for some time past precluded the possibility of getting Peas raised under glass planted in their permanent positions outdoors. Advantage should be taken of the welcome change to get this carried out now and as the planting proceeds to mound and stake them without delay, placing plenty of fine spray between the sticks on either side of the rows to shelter the plants from cold, cutting winds. A sprinkling of soot or Tobacco powder on the leaves and tips of the shoots deters sparrows and wood pigeons from attacking them.

The Potato Onion.—The bulbs, if not already planted, ought to be got out without delay. Plant 3 inches or 4 inches deep, and as top growth progresses lightly mound them up. In a season when Onions have kept none too well, the value of this old underground variety is undeniable. For planting use good-sized bulbs, for small sets will often merely increase in size, instead of breaking up into offsets as they ought to do.—K. B. T.

PERPETUAL-FLOWERING CARNATION SOCIETY.

MARCH 29TH, 1916.

NEITHER the flowers nor the competition were up to their usual standard on the occasion of the twentieth exhibition of the Society held at the Royal Horticultural Hall on the above-named date. No doubt the exceptionally wet, sunless weather of the weeks preceding the show were responsible for much inferior flower quality, the lack of competition, to the abnormal circumstances prevailing at the present time. To some extent, also, the show suffered, owing to interrupted railway conditions. These things notwithstanding, there were many good vases of flowers and an exhibition of general interest. No novel feature was introduced, while some of the exhibits in the decorative classes, e.g., baskets and epergnes, were, we thought, of the retrogressive rather than the progressive order. No new variety of Carnation received an award. There was no competition for the Branton Challenge Cup or for the Lord Howard de Walden Challenge Vase.

OPEN CLASSES.

In the leading class for twelve vases of Carnations, twelve varieties, twenty-five blooms of each, for which the first prize is the George Monro, Junr., silver-gilt challenge cup, value fifty guineas, two competitors entered, the cup being awarded to the Clury Nursery Co., Langley, for a fine lot of flowers. The varieties were British Triumph (crimson), White Enchantress, Sunstar (yellow), Baroness de Brien, Enchantress, Lady Meyer, Enchantress Supreme, Lady Northcliffe (all pink shades), Beacon (scarlet), White Wonder, and Mrs. C. W. Ward and Gorgons (cerise), both excellent. With better arrangement—it was generally too lumpy—this would have made an imposing exhibit. Messrs. W. Wells, Limited, Merstham, were second. Lord Kitchener, Aviator, Champion, and Pink Sensation being their finer flowers. Messrs. Wells were the only competitors for the challenge cup offered by the American Carnation Society for three vases of twelve blooms each, the firm staging Good Cheer, Aviator, and Pink Sensation, the last of outstanding merit. Only one exhibitor, Mr. J. C. Jenner, Rayleigh, staged seven vases of Carnations, seven varieties, twenty-five blooms each. The varieties were Mary Allwood, White Wonder, Mrs. C. F. Raphael, Enchantress Supreme, Satin Robe, Salmon King, and Carola (crimson). Only the last and White Wonder were first class. Mr. H. T. Mason, Hampton Hill, was first for five vases, distinct varieties, twenty-five blooms each. His set comprised Warrior (good crimson), Beacon, Enchantress Supreme, White Enchantress, and Lady Fuller (deep pink). Mr. W. H. Page, Tangley Nurseries, Hampton, took first prize for three vases under similar conditions, having White Wonder, Beacon, and Lady Fuller. The exhibit was rather overdone with Carnation foliage. Three competed for the single vase, one variety, twenty-five blooms, Messrs. Wells leading with an excellent lot of Pink Sensation. Mr. W. H. Page was second with Philadelphia.

OPEN TO GENTLEMEN'S GARDENERS AND AMATEURS.

For three vases of Carnations, twelve blooms in each, six varieties, two varieties in each vase, the first prize was awarded to Major Sir R. Baker, Bart., M.P., Blandford (gardener, Mr. A. E. Usher), who associated Mikado and Wonder, Benora and Baroness de Brien, and Carola and Mrs. C. F. Raphael respectively. The

same exhibitor also took the first prize for three vases, eight blooms, two varieties in each vase, combining Penora and Carola, Marmion and Baroness de Brien, and White Enchantress and Mikado, against four competitors; for three vases, six blooms in each as above; one vase, twelve blooms, one variety; one vase, nine blooms, one variety, having Carola in each case; and one vase of Carnations, nine blooms, three varieties, where Champion, White Wonder, and Mrs. Ward were employed. The Countess of Derby, Sunningdale (gardener, Mr. W. J. Reed), led in the class for twelve blooms, three varieties, with Carola, Mikado, and R. F. Felton, and took first prize for the vase of five blooms in at least three varieties raised and grown by the exhibitor.

DECORATIVE CLASSES.

For the dinner-table decoration of Carnations four competed, Mrs. Alex. Robinson, Park Hill, Carshalton, taking the premier award, and showing good taste and some originality. She used dark brown fancy baskets with bowls therein and employed Lady Northcliffe Carnation in capital condition, interspersed with Thorn twigs just breaking into leaf, Salix sprays with woolly catkins, Bramble sprays whose leaves matched the baskets for colour, and trails of miniature-growing Ivy cleverly introduced. It was the only good object-lesson of the meeting. Mr. W. Heath, who was second, employed the same Carnation, with Cytisus and Asparagus sprays. The arrangement struck us as a little untidy. Mrs. A. R. Bide, Farnham, had by far the best decorated basket of Carnations, employing the rich scarlet and white fancy variety, Fanny, with touches of Croton leaves and Asparagus. It was at once good, attractive, and not overdone. Those of the second and third prize-winners were hopelessly heavy or over-coloured. The decorated vases or epergnes of Carnations were of service only as demonstrating what not to do. We have rarely seen a worse lot; a more heterogeneous mixture.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM MARCH 30TH.—*Daphnes* (in variety), *Laurustinus* (various), *Alnus cordifolia*, *Arbutus canariensis*, *Ericas* (in variety), *Andromedas* (various), *Berberis* (various), *Azara microphylla*, *Almond* (*Prunus Amygdalus*), *the Purple Plum* (*Prunus Pissardi*), *single and double Camellias*, *Osmanthus Delavayi*, *Forsythia spectabilis*, *Cydonias* (in variety), *Skimmias*, *Osoberry* (*Nuttallia cerasiformis*), *Ribes sanguineum*, *Periwinkles* (various), *Rhododendron venustum*, *R. Jacksoni*, *E. ciliatum*, *Salix caprea*, *Dog's Tooth Violets* (in variety), *Wallflowers*, *double and single Arabis*, *Aubrietias*, *Violets*, *Polyanthuses*, *Snowflakes*, *Aconite*, *Narcissi* (in several varieties), *Snowdrops*, *Grape Hyacinths*, *the Notted Iris* (*I. reticulata*), *the Algerian Iris* (*I. stylosa*), *Scillas* (in variety), *Puschkinia scilloides*, *Veronica filiformis*, *Milkwort*, *Crocus* (in great variety), *Pulmonaria saccharata picta*, *Glories of the Snow* (*Chionodoras*) (in variety), *Hepaticas* (in variety), *Anemones* (in great variety), *Saxifrages* (various), *Lenten Roses* (several varieties), *Candytuft*, *the Great Pilewort* (*Ficaria grandiflora*), *Violet Cress*, *Forget-me-not*, *Hyacinthus azureus*, *Fumitory*, *Blue-eyed Mary* (*Omphalodes verna*), *the Bitter Vetch*, *Synthlipsis reniformis*, *Corydalis* (in variety), *Hutchinsia alpina*.

WORK OF THE WEEK.—The weather has again been most unfavourable for outside work, snow having fallen almost daily, therefore the repairing of garden-paths, which began to show signs of wear from the constant heavy carting, has been attended to. The paths are formed of sandstone, and as it is possible to quarry this on the place, advantage was taken of the bad days to get out a good supply of material with which the damaged paths were brought up to their proper level, the whole being given a coating of fine material and finally well rammed. The centre is raised so that the water quickly finds its way to the drains. Another new path has also been formed of the same material, and as this lies lower than the border on one side it was

necessary to put down a single line of sandstone blocks 9 inches deep, which will prevent the soil being washed over the walk, at the same time providing a place for some choice edging plants. Cuttings of the blue Bindweed (*Convolvulus Mauritanicus*) have been potted off, and those raised from seeds have been given a shift into larger pots. Cuttings of the False Heath (*Fabiana imbricata*), inserted in autumn, have been potted off. These have been in a cold frame all the winter. Later sowings of Sweet Peas have had small stakes placed among them and transferred to cold frames. Snapdragons have been pricked off into boxes, and will be kept in a warm-house for a time. The forking over of vacant ground intended for annuals is being done. Pruning of bush Roses continues, and the beds are cleaned and forked over as the work proceeds. Beds carpeted last season by Tufted Pansies will be given a change. Where the Pansies have come safely through the winter they have made fine plants. These are being carefully lifted and replanted in beds hitherto filled with other subjects. A bed of China Roses is being carpeted with Tufted Pansies, and a bed of Gladiolus Brechleyensis has been likewise planted with Giant Summer Forget-me-not. Other beds have been prepared for Perpetual-flowering Carnations and Cannas. For the Carnations lime was freely used. *Perovskia atriplicifolia* has been pruned back to a few eyes as this fine shrub will soon be on the move. Some of the slender-growing Heaths have been badly broken by the snow falling from the trees above them. E. M. Sussex.

SOUTHERN COUNTIES.

Mint.—This, being in demand more or less for nine months out of the twelve, it is necessary if a break in the supply is to be avoided that a new bed be planted occasionally. The present is a good time to do this, as the roots are active and well furnished with growth on the point of pushing through the soil, consequently they start growing at once and soon become established. A piece of ground of suitable area—preferably a portion of a border facing south when an early supply is needed—should be marked off, manured, and then dug. If in good working order planting can take place at once, but if the soil is at all sticky an interval of a few days must be allowed for it to dry sufficiently so that the surface, after being lightly trodden, can be raked down to a fairly fine condition. The roots should be laid out regularly, but not too close together, on the prepared surface, and then covered with 2 inches in depth of fine soil, which should be made firm by lightly beating it with the back of a spade. If dry weather intervenes between the time of planting and before the roots have got a good hold of the ground, an occasional watering is beneficial. Existing beds are always the better for a light top-dressing either of some old potting soil or decayed hotbed material after it is freed of sticks and any other extraneous matter by passing it through a coarse sieve.

Asparagus.—To allow of the oldest bed being broken up each year for forcing, as well as to make sure there shall be no falling off either in the supply or quality of the outdoor produce, one or more new beds should be made each year. These may be formed either by planting with one-year-old roots or by sowing seed, the latter method being preferred in my own case. Although a longer time elapses before the plants come into full cut, it is the least troublesome way of establishing a bed, and while, as a result of there being no root disturbance, the crowns are thoroughly established when the third year is reached, the quantity and quality of the produce are all that can be wished. The present is a suitable time to sow the seed. This may be done on the flat in light, friable, and sandy soils, but in those of a heavy nature it is best to raise the beds above the surrounding level beforehand. The beds may be 3 feet, 4 feet, or 5 feet wide, with 3 feet alleys between. The first will accommodate two rows, and the two latter three rows of crowns each. To raise the beds to the requisite height at the outset the soil is taken out of the alleys to a depth of 6 inches and spread evenly over them. The edges are beaten down firm with the back of a spade and then cut true and perpendicularly with the aid of the same implement and a garden line. A stout stake driven in at each corner completes the job. The drills are drawn 2 inches deep, and four to five seeds are dropped into them at intervals in groups, each group standing about 15 inches apart. When germination takes place and the plants develop sufficiently for the strongest to be distinguished, they are reduced to one in each group. The site for the beds should be prepared some time in advance of seed-sowing so that the surface may become mellowed and in good working condition.

Bedding plants.—As these are now not only occupying valuable space, but are doing no good where they are in the heat of fruit houses, they will be taken out and placed in cold pits to undergo a proper hardening off. If well watered before being removed no harm will accrue if they should get dry for a few days, by which time they get somewhat inured to their new surroundings and not so liable to suffer when watered. The foliage being tender, a little shade from direct sunlight is also neces-

sary for a few days. For the present the precaution must be taken to mat the pits down at night.

Herbaceous Calceolarias.—The flower-spikes are pushing up fast and require a neat stake to support the main stem. Feeding with liquid-manure is now being done as the pots are crammed full of roots and in need of further supplies of nutriment, that in the soil having become exhausted. The forwardest plants of Clibran's Calceolaria are also receiving mild doses of liquid.

Malmaison Carnations.—These are now being staked out and tied, the larger specimens being allowed from four to five Bamboo stakes each for their support and the smaller ones, or such as will carry but a single bloom, one each. The roots now being in fit condition for the assimilation of a stimulant, they will be fed with Carnation manure. Having a house devoted entirely to them, free ventilation is accorded at all times, frosty nights excepted.

Indian Azaleas.—With a view to having a plentiful supply of white flowers for the Easter festival, a good few bushes with prominent buds have been placed in a late vinery to be forced gently into bloom. At the present time that old variety Fielder's White is supplying a fine lot of long-stemmed sprays for cutting. This variety stands cutting with impunity, as any loss of wood is always made good by the production of free and vigorous growth directly the flowering period is past.

Poinsettia pulcherrima.—A portion of the plants which have been resting under a stage will be brought forward, cut back somewhat, and placed in heat to afford cuttings for the raising of the earliest lot of plants to flower in late autumn.

Fuchsias.—Plants which were cut back in January broke well and have since been partially shaken out and shifted into pots two sizes larger. They are now making excellent progress, and the shoots will soon receive the first stopping. If they continue to make good growth they will again be pinched and then allowed to flower. Successional batches of plants will be similarly treated very shortly, both in regard to shaking out and repotting. With respect to stopping of shoots, they, unless the plants should be required earlier than is anticipated, will be pinched three times before being allowed to bloom. These will make nice hushy plants by the end of the summer. Some plants which have got either too leggy or unwieldy for further indoor purposes, will, when they have been hardened off, be planted outdoors among the dwarf shrubs. Cuttings put in early in the year have been potted off and will now have the points pinched to make them break and become bushy.

Bouvardias.—Plants of such varieties as President Cleveland, Bridesmaid, etc., which were cut back some few weeks ago have broken well. The plants have been relieved of some of the old soil and given a shift into pots two sizes larger.

Streptosolen Jamesoni.—A good few plants which were cut back at the same time as the preceding have been partly shaken out and repotted. Plants in 5-inch pots are found very useful.

Flower garden.—The cleaning and digging of the herbaceous and shrub borders and beds which have so many times been interrupted through stress of weather have now been brought to a conclusion. The edges of walks have been hoed and all made as clean as circumstances permit. The pruning and training of creepers and Roses on walls are progressing and will shortly be finished. As soon as the weather becomes more settled and warmer, border Chrysanthemums will be planted. The plants in the meantime are being well hardened by exposure in the daytime.

Strawberries.—A number of plants intended for forcing to supply fruit during this and next month has been planted out in the open in rows 2 feet apart and 18 inches distant from each other. Under favourable conditions these should yield a good crop of fruit. A. W.

MIDLAND COUNTIES.

Climbing conservatory plants.—Many of these are now making new growth, and the young shoots require to be regulated with a view to furnishing the allotted space on the trellis and preventing crowding and entanglement. This applies more particularly to such plants as *Lapagerias*, *Tacsonias*, *Hibbertias*, *Dipladenias*, *Thunbergias*, etc.

Genistas.—As these plants are now going out of flower, all the weak shoots will be removed and the chief ones shortened sufficiently to make shapely plants. Plants which are in need of more room will be repotted forthwith. To start the plants into growth they are placed in an intermediate temperature and syringed daily. They must be afforded full light or they will fail to flower satisfactorily. If an increase of stock is desired, cuttings may now be put in, selecting shoots that have no flowers or that have not bloomed. Insert the cuttings round the rims of pots filled with light, sandy soil, and place

the pots in moderate heat. I prefer to raise a few plants every year and throw away those that have been cut back for two or three years.

Gladioli.—The early-flowering varieties that were potted early are now being gently forced into bloom. The Gladiolus will not stand much forcing, the flower-buds turning yellow and dropping off if it be attempted. The general stock will, for the present, be grown on steadily in a cool-house.

Hardy Ferns will soon be pushing up their new fronds. Last year's fronds may now be removed. If there are no bulbs growing among the Ferns the surface-soil should be very lightly pricked over and a good dressing applied. Most Ferns delight in a heavy mulch of half-decayed leaves, which not only conserves the moisture, but also provides a good rooting medium.

Michaelmas Daisies.—Plants obtained by potting up small portions from the outside borders early in the season are now in good condition for planting out. Large beds filled with one or more varieties have a fine effect in the autumn.

Rose cuttings put into pots last autumn and wintered in a cold-frame are in a suitable condition for planting out. I find a cool west border suits them best until they are large enough to go into the permanent quarters. They should be put out now, even if they are not rooted, for if well callused they soon form roots and grow away freely. Nearly all the Ramblers and Rugosas root

should be placed round the plants to lead them up to the taller bushy sticks, which should not be less than 8 feet or 9 feet high, and should be put in at once, keeping them well away from the plants. It is a good plan to put a string or wire round the whole to keep them together, otherwise they are liable to displacement by strong winds.

Potatoes.—There should be no delay in getting the maincrop Potatoes planted during the next fortnight. If late frosts occur, a little fine soil can be drawn over the tops, and should a wet autumn follow, disease will be less prevalent than when late planting is practised. Continue to prick out

Brussels Sprouts, Cauliflowers, and early Broccoli, which have been raised under glass, on warm, sheltered borders as they become ready.

New Zealand Spinach is one of the most useful vegetables, especially in hot, dry seasons where Spinach is in demand, and yet for some reason it is little grown. It appreciates a hot, dry summer, and when cooked can hardly be distinguished from the other. One or two sowings should be made during April in boxes, planting out in a sunny position on fairly rich land in May. It is somewhat tender, and must be protected against frost, especially when young.

Chicory is very useful when salads are in demand during winter, as it is not only easily cultivated and blanched, but it forms a splendid substitute for Endive, which is often

plants in beds in cold-frames for early use. A further sowing was made for outside planting. The varieties preferred are Long Green and Long White.

Celery trenches.—A couple of Celery trenches have been opened. Into the bottom of these a good layer of well-rotted manure was worked, and about 4 inches of sifted vegetable mould were placed on the surface. The beds thus formed are valuable in many ways. In them are planted temporarily such things as Tufted Pansies, Calceolarias, Marguerites, hardy Chrysanthemums, Pentstemons, and such like. In the trenches these things root well into the fine soil, and can be transferred to their flowering quarters when the time arrives with fine balls and with little check. As the season advances half-hardy annuals, such as Stocks, Asters, and Marigolds, will be pricked off into the trenches. These, too, invariably do well treated in this way. Should frosts occur, the plants can be readily protected by laying Pea-stakes across the ridges or placing mats supported on posts over them.

Vegetable garden.—In the early part of the week a considerable amount of progress was made. Spent vegetables were removed, and the quarters occupied by them were deeply dug after having been well manured. The break occupied by Leeks has been cleared in order that it may be turned over at an early date. The Leeks have been laid in thickly at the end of a quarter previously dug, where they can be easily got at, and in which they

Marquette Carnations in a vase.

very freely, and are much best on their own roots. A great many of the Teas, Hybrid Teas, Chinas, and Polyanthas also root easily and are quite free on their own roots.

Rose hedges.—If these have become bare at the base, now is the time to remedy matters by hard pruning. If the plants are well established many growths may be cut down level with the ground. In fact, the whole hedge can be so treated if desired, but such drastic treatment is rarely necessary. The unfurnished condition of the base of a hedge often arises from a bad start. If the plants are cut hard back after they have been planted twelve months they usually grow strong and bushy, and if one or more of the oldest growths are cut down hard each year, a constant succession of young wood from the base is secured.

Clematises being plants of free growth, attention must be given to the young shoots when they are growing freely, regulating and tying them to prevent them becoming tangled or injured by the wind.

Sweet Peas sown in pots and raised under glass are now good, sturdy plants several inches high, and, having been thoroughly hardened off, will, as soon as the weather is favourable, be planted out on ground which has been well prepared. Rows or hedges of Sweet Peas are very attractive. They can also be used to mask an unsightly place during summer, but the most effectual way of growing them is in separate colours planted in clumps. When planting make the ground fairly firm about them. A few small sticks

none too plentiful during midwinter. Make two or three sowings, the first now on deeply cultivated soil. Sow in shallow drills 1 foot apart, and thin the plants to the same distance.

Onions raised in heat and carefully hardened off are now fit for planting, and, provided the weather is favourable there need be no further delay in so doing, for the plants will grow more freely in the open. If ample ground is at command the rows may be 2 feet apart, which will allow of working among the plants without damaging the brittle leaves as they become larger. When fairly dry, tread the ground well, then rake over roughly and roll it, afterwards again raking it and drawing shallow drills. Lift with a good ball of soil, and plant 1 foot apart in the row with a trowel.

Leeks.—The early-raised plants can likewise be put out. Take out a trench in a similar manner as is done for Celery, placing a good thickness of decayed manure in the bottom, on which lay 6 inches of good soil, then tread lightly and plant 1 foot apart down the centre.

F. W. GALLOW.

SCOTLAND.

Vegetable Marrows.—Seedlings from the earliest sowing were potted on during the week into 5-inch pots. These will yet awhile be given a little heat until the weather will permit of their being removed to a frame to be hardened off. It is intended to grow these

will keep quite well until required. A stretch of cold-frames was filled with seedlings of Brassicas of various kinds, including several varieties of Cauliflowers, a midseason Cabbage, Curly Kale, Brussels Sprouts, and Savoys of the Drumhead type. The trouble involved in this handling of the seedlings is always amply repaid, the plants being much more robust and a trifle earlier than those from the usual nursery beds in the open. Successional sowings of Broad Beans and of Peas are being attended to as becomes necessary. Taylor's Broad Windsor Bean and Duke of Albany and Stratagem Peas are useful varieties for present sowing. A sowing of Henderson's New York Lettuce was made in pans during the week. This is a Cabbage variety of some merit, which matures in a comparatively short time, and which remains in good condition over a prolonged period. More Parsley was pricked out into a frame, and autumn Onions were looked through, and such plants as were by stress of the east winds rather loose were firmed up. Toward the end of the week a snowstorm of some severity put an end to the work on the soil for the present.

Lime-washing.—Taking advantage of the stormy weather all the needful lime-washing has been done among plant-houses, pits, and frames. This is, as a rule, done twice each year. Not only does lime-washing give things a tidier and cleaner look, but it clears off fungoid growths and disposes of insects and their eggs which may be present in nooks and crannies. The inside walls of plant-houses were attended to at the same time, any plants

which interfered with the work being loosened until the wall was washed, and afterwards regulated, pruned as was necessary, and retied. The refuse lime is always thrown on the manure heap, where it is of value.

Boxwood.—In the beginning of the week a start was made with the annual trimming of Boxwood. To many this may appear rather early, but this practice has been followed for many years with the best results. There is a large quantity of Box to be attended to, and it is (purposely) permitted to grow higher than is usual, so that it takes a long time to get over it all. At the present time, before the busy season really starts, it is, therefore, considered advisable to push on this work, and, as has been said, no evil results follow the trimming of the Boxwood so early in the year.

Hardy fruit.—Growth is increasingly active among hardy fruit-trees, and the usual precautions customary at this time are being taken. Gooseberries, being wired in, are free from the attacks of bud-eating birds, but they are at times (perhaps owing in part to their being enclosed) liable to trifling outbreaks of caterpillar. Now that the bushes are uniformly green they have been freely dusted with soot. This keeps the fly from depositing its eggs in the tissues of the young foliage; and by and by a second dressing will be given. This is, generally speaking, sufficient to prevent damage being done, and the summer rains clean the foliage and prevent any unsightliness. There is, fortunately, no "big-bud" among Black Currants in these gardens, but, as it is known to exist in the neighbourhood, a close inspection is made from time to time in order that any incipient outbreak may be promptly dealt with. Strawberry beds have been dressed with a quick-acting chemical manure and well hoed up. The plants, as a whole, have come through a rather unfavourable winter in a satisfactory way. The flowers of the earliest Peaches and Nectarines on south walls are on the point of expanding, and protection is being given at night when frost threatens. Plum-trees are very little behind. The promise of bloom is gratifying; but so much cannot be said in the case of Pears. Certainly the majority look very promising, but the appearance of some trees—notably Beurré Hardy and some young trees of Dovenné du Comice—is not so good as usual. Apples, both on walls and in the open, promise well, and the same may be said of Morello Cherries, both old and young trees.

Fruit-trees in pots.—These, having been kept as cool as possible, are now in bloom, and are fertilised daily when the sun shines and pollen works freely. In the case of trees in pots, regular attention is now necessary in respect of moisture, and the trees ought to be inspected twice a day. As soon as the petals fall and the set is assured, the syringe must be got to work. This is done twice a day round about 7 a.m. and again at present about 4 p.m. As the sunshine increases, the afternoon syringing will gradually be done later, but never after 5.30 p.m. If it is possible to partly plunge the pots less watering may suffice.

Thinning fruits.—It always pays to attend to the thinning of Peaches and Nectarines under glass at as early a date as possible. At the same time thinning must not be rushed—that is to say, it is much better to spread out the operation and thin by degrees. The same remark applies to disbudding, and in both cases badly-placed fruits or shoots ought to be removed first. There is always a certain amount of fruit-dropping at stoning time, so the final thinning may be delayed until after that time. In the case of Grape thinning, it may be feared that the work will be prolonged over much more than the customary time. Grape thinning is not learned in a day, and there is a great scarcity of skilled thinners. This will, however, result in young lads getting a chance which they might not otherwise have had, and which will be beneficial to them. Beginners are never, as a rule, apt to be too severe in their methods, and when once a sharp lad who has an intelligent interest in his work has learnt how to thin it is surprising how soon he improves.

Ferns under glass.—Among recently-repotted Ferns growth has been rapid and regular. With the greater strength of the sun it is now advisable to shade the young fronds from the direct rays, otherwise there is a danger that they may be scorched. It is, perhaps, rather too early to obscure the glass permanently, and it is better to shade the plants by means of temporary screens, which can be removed after sundown or during sunless days. Such shade can be easily afforded by placing a few moderately long canes among the plants upon which tiffany or newspapers can be placed. In the course of the week a number of young Pterises of various kinds was potted into 3-inch pots. Such young plants are useful in many ways, and as they are of no great value, should odd pieces come to grief when employed in small vases the loss is not grudged. *Adiantum Henslovianum* has been given a thorough trial among the other varieties of the family grown in the ordinary temperature. While it has done fairly well, the plant never had the appearance which it had when grown (like *A. Farleyense*) in the stove, and so it has been replaced in the warmer house.

CORRESPONDENCE.

Questions.—*Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly written on one side of the paper only, and addressed to the EDITOR of GARDENING, 63, Lincoln's Inn Fields, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, the name and address being added to each. As GARDENING has to be sent to press some days in advance of date, queries cannot always be replied to in the issue immediately following their receipt. We do not reply to queries by post.*

Naming plants.—*All who wish their plants to be rightly named should send fair examples of each—the stem, leaf, flower, or fruit. (Snippets of leaves and points of shoots are useless.) Not more than four plants should be sent in any one week by the same correspondent. Where more than one kind is sent they should be numbered. Of course the fruit should always be sent.*

Naming fruit.—*Several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. We can undertake to name only four varieties at a time.*

PLANTS AND FLOWERS.

Cytisus racemosus losing its flower-buds (P. D.).—The most general cause of this plant losing its flower-buds in the manner complained of is that it is grown in too high and dry a temperature, or that it has been allowed to suffer from want of moisture at the roots, and then heavily watered. To grow this *Cytisus* well it should be kept in a cool house from which frost is just excluded.

Astilbe (Spiræa) japonica in pots not flowering (J.).—The plants should have been divided and planted out in a sunny border of good, rich soil for a couple of seasons. They will not go on flowering perpetually in pots without some recuperative treatment. Divide at the end of March and plant out, allowing them to remain until they become strong clumps, then pot up again. When dividing, a large root may be cut into three or four portions.

Ferns under a bell-glass (A Fern Lover).—Your bell-glass would be very suitable for a plant of the Killarney Fern (*Trichomanes radicans*). Begin by putting plenty of drainage in the bottom of the pan, then a little Moss, and use a compost mainly of peat, with a little loam or leaf-soil, with a number of pieces of sandstone about the size of marbles in it. If you can stand the Fern-pan in another pan of water, so as just to touch the bottom of it, it will be an advantage. Do not let this Fern stand in the sun.

Chrysanthemum cuttings flagging (P.).—A shelf in a greenhouse is a very bad place for newly-pit-in Chrysanthemum cuttings, as there they would be sure to flag. If a slightly warm and rather close frame is not available, then cover a portion of the stage in the greenhouse with a few slates, and on these place some Coconut-fibre. Stand the plants on this and cover them over with a hand-light. Do not allow the soil in the pots to become dry, and the cuttings will soon strike root if not already too much dried up by being placed on the shelf.

Growing Ten-week Stocks (C. R.).—Ten-week Stocks sometimes go off with a disease known locally as blackleg, which is chiefly caused by sowing early in heat, and permitting the plants to remain too long in the seed-pans. With more rational treatment, not so much forcing, sowing thinly, and pricking off as soon as they can be handled, and hardened in cold frames, there will not be much risk of failure. Dressings of lime and soot are always beneficial; and it may be necessary to change some of the soil. When the same beds are planted with Stocks every year, a little sulphur dusted among the young plants will be beneficial.

Daffodils not flowering (Disappointed).—As the bulbs are planted amongst shrubs the reason of their not flowering is obvious. They cannot have sufficient nourishment to perfect and mature the bulbs, or the bulbs themselves may be crowded too closely together, and require removal to fresh ground. They ought to be replanted once in three or four years, when the bulbs are quite at rest—say, in August, or perhaps in July. Plant the bulbs in deep, rich soil, if in clumps, 4 inches or 5 inches apart. They might not flower well the first year after planting, but would do so

abundantly in subsequent years—that is, if the plants have a fair exposure to light and air. If the bulbs are planted under bushes they cannot do well, as not only are light and air excluded, but the roots of the bushes exhaust the soil to an alarming extent.

TREES AND SHRUBS.

Pruning Laurels (J. R. Morton).—The best time to prune Laurels is during the spring—say, early in April. The shoots made following the cutting get firm before the winter, otherwise a spell of hard frost is apt to cripple them should a cold, damp autumn follow the summer growth.

VEGETABLES.

Growing Tomatoes in a greenhouse (Tomato).—It is an easy matter to secure a crop of Tomatoes in an unheated house during the months of July, August, and September. You should purchase good, strong, well-hardened plants in pots towards the end of this month, and as soon as they have got used to the house—say, a week afterwards—plant them out. Do not grow them in pots, if it can be avoided, but set them out in mounds, or in a ridge of good, loamy soil, placed on the front bed or stage. About $\frac{1}{2}$ bushel to each is enough to start them in, adding a little more on the surface from time to time during the season. Place them from 12 inches to 15 inches apart, and train them to a single stem. Good turfy or fibrous loam, with a fifth or sixth part of thoroughly decayed hotbed manure, and a little soot and bone-meal, forms about the best compost. It is not well to use rich soil at first, nor to give much water until the plants commence fruiting; but when the fruits are swelling freely the plants may have liquid manure at almost every application with advantage.

MISCELLANEOUS.

Brick pits v. frames (F. Q.).—There are both advantages and disadvantages in brick pits over frames and hotbeds. The advantages are: less manure is required, and the heat is economised, being retained with brick walls, cold rains and wind being excluded. On the other hand, brick pits are more costly, and if the heat declines too rapidly there are not the same facilities for renewing it with linings, as in the case of a hotbed. Of course, the brick pit has a neater appearance in the garden as the hotbed always makes a litter. Stout boards would make a useful pit, and be nearly as warm as bricks, but not so lasting, though it would be cheaper in the first construction. A useful brick pit would be 4 feet high at the back and 2 feet 6 inches to 2 feet 9 inches at the front, and may be excavated 1 foot deep. If excavated more it would be very damp in winter as a store pit. From 5 feet 6 inches to 6 feet would be a convenient width.

OBITUARY.

MR. R. H. FREMLIN.

We have lately lost a very interesting gardener of Wateringbury, in Kent. Mr. Fremlin was a true lover of hardy flowers, and knew well what to do with them. I had often seen plants in particularly good soils, like those round Edinburgh, in which hardy flowers grew finely, but for many years I had not seen them do so well as in Mr. Fremlin's garden. He told me it was the best Hop soil in the county, and the flowers we so often cultivate with difficulty flourished in that soil and were very charming to see. After spending several hours with him among the flowers on the lawns it was a pleasant surprise to get into the shade of a group of trees and find there a colony of the giant Forget-me-not in splendid health. This garden and a few others make one doubt if any preparation of mixed soils ever gives so fine a result as a naturally friable and good soil. He was one of the first of the few to bring hardy flowers of the best into the garden landscape, so to say, and with singularly good effect, and not merely in mixed border or the hungry margins of shrubbery. We have had the pleasure of illustrating in past issues various rare plants of his collection. W.

NOTES OF THE WEEK.

The Blizzard on Tuesday, March 28th, was very severe in this locality, uprooting many trees and doing immense damage to many fine Cedars, Yews, and other shrubs.—F. W. GALLOP, *Lilford Hall Gardens, Oundle.*

Primula Winterei in S.W. Scotland.—*Primula Winterei* has stood the winter here quite well. It is on a sloping moraine facing south-west, and has had no covering of any kind during the winter, which has been a most trying one for many plants.—S. ARNOTT.

Lonicera nitida.—A shrub which seems to approve of this extraordinary season is *Lonicera nitida*. A fine specimen about 2½ feet high is quite covered with flower-buds. It was planted, I think, in 1913, and has never before shown signs of flowering.—E. CHARLES BUXTON, *Coed Derw, Bettws-y-Coed.*

The Green Snowdrop.—A nice little group of the curious green Snowdrop, *Galanthus nivalis virescens*, was in bloom in the rock garden at the Royal Botanic Gardens, Edinburgh, on April 5th. It is the latest of the Snowdrops and is rather singular with its green markings on the exterior of the outer segments, and the almost total emerald colouring of the interior.—ESS.

Prostanthera rotundifolia.—This shrub was one of the numerous attractive plants at the Royal Botanic Gardens, Edinburgh, the other day. It is a charming little shrub with neat leaves and labiate flowers of a pleasing blue or purple. The *Prostantheras* are not much grown in private gardens, but are worth considering by those who care for out-of-the-way shrubs. It is a native of Australia.—S. M. D.

Orange-berried Holly and birds.—Looking round to-day (March 28th) I notice that a good-sized tree of the above has been untouched by the birds. After such a spell of bad weather as we have had lately it struck me as rather unusual that a tree so loaded with fruit should be ignored while the scarlet berries of trees in the same group were cleared off in a few hours by the missel thrush and other birds.—E. M.

Narcissus capax fl.-pl.—It is rather disappointing to find that the blooms of Queen Anne's Double Daffodil are much fewer than is generally the case. This is always a favourite, and it does not seem

to grow cheaper—that is, in comparison with other varieties. Probably this may be, in some measure, attributable to the slowness of increase among the bulbs, one clump with me having grown only very slightly larger during the last twenty years.—W. MCG.

Poisoning from Daffodil bulbs.—At a meeting of the Edinburgh branch of the Pharmaceutical Society of Great Britain a communication was made by Mr. W. G. M'Nab on a case of poisoning from Daffodil bulbs. Poisonous symptoms had followed partaking of soup and afterwards of stew containing what were supposed to be sliced Onions, but which proved to be bulbs of *Narcissus pseudo-Narcissus*. The bulbs had been stored in the same house as the Onions, and had been taken by mistake. Similar cases of poisoning have been recorded and traced to the alkaloid pseudo-narcissine.

Diervilla rosea for cutting.—Looking round the other day, the progress made by a group of *Diervilla rosea* is worth noting. These shrubs were planted a little over a twelvemonth ago, and, as was to be expected, did not bloom very freely last season. They are in a rather holding dark loam and have made considerable progress, appearing to be suited with their position, which is slightly shaded. The flowers, when cut in the bud state, expand freely in water, and in the same state bear a long railway journey well, arriving, I am told, in excellent order and remaining effective for a considerable time.—KIRK.

Lithospermum rosmarinifolium is in most abundant bloom. I am not sure that its clear blue clusters of flower are still brighter and more abundant than in the familiar *L. prostratum*, but it has the merit of growing in calcareous loam, which is fatal to *L. prostratum*, and, moreover, flowers all the winter, which is a great merit. I wish some clever hybridist would furnish us with a hybrid between the two that would take after *L. rosmarinifolium* and grow on limestone, while retaining the hardness of *L. prostratum*. It would indeed be a plant for everyone. Saxifrages are being hybridised every day; why not *Lithospermums*?—E. H. WOODALL, in *The Garden*.

Anemone blanda scythinica.—This distinct variety of the Greek Anemone is now (March 25th) in bloom. The flowers, when fully expanded, are white, heavily shaded with blue on the underside of the lower

row of petals. The above variety seems to be the gem of the lot and is increasing freely with me on a bed which catches the morning sun. There are pink, blue, and white forms of *A. blanda*, all of which are early and suitable for carpeting the ground below Roses and other shrubs, naturalising in the Grass, or growing through permanent edgings to flower beds. The *A. blanda* forms are easily distinguished from the Apennine Windflower by their rather larger flowers and round, bulb-like roots, the latter having a creeping rhizome and flowering later.—E. M.

Tulipa saxatilis.—This reminds one so much of a larger and brighter *T. sylvestris*; its way of running at the root and popping up in unexpected places is so amusing when left to itself in a dry, rocky soil. It enjoys calcareous clay, but I fancy it thrives in sandy soils also. The pretty way its buds and half-opened flowers hang their heads is most original, and the tender pink of the widely-expanded bloom is very pleasing, especially when three or more flowers are open on one bulb. Altogether it is a great gain to the spring garden, and it is best when left to take care of itself—another great merit, as it can cover a considerable area.—E. H. WOODALL, in *The Garden*.

Andromeda formosa.—Flowers of this noble evergreen flowering shrub have come to me from Knap Hill. They were so well flowered that I had to ask Mr. Waterer how they came about, and this is what he says:—"The winter always kills the buds with us, so I put it into a cool-house, and as it came out well I send it you, and am very pleased you like it. I suppose it would flower in Cornwall and Devonshire. Here it is hardy in a sheltered position as far as the plant is concerned, but the buds are always killed in the winter." The flowers are certainly very much stricken by frost, and it is one of the things well worth growing out-of-doors in some simple way and then transferring to a cool-house for the sake of its beautiful flowers.—W.

Sea sand.—The note by "Kirk," on page 137, should remind readers that sea sand may be more freely used by those who live by a sandy sea beach or are within reasonable distance of such and without a ready supply from other sources. I used sea sand for a number of years for every purpose for which silver and other sands can be utilised, and generally fresh from the shore. In my case the proportion of shell was not large, but many particles

were present in the sand which was used as collected. This sand contained a perceptible amount of salt, but it never did any harm to cuttings, seeds, or plants. It was regularly employed for every purpose, including putting round corms of Gladioli when they were planted. Cuttings struck in this pure sea sand succeeded perfectly well. I employed it for eighteen or twenty years, and, were I again in possession of a garden by the sea, I would revert to the use of sea sand with every confidence.—S. A.

Christmas Roses: Treatment and time of planting.—Christmas Roses like a deep, rich soil in partial shade and sheltered from boisterous winds. The bed must be 3 feet deep, and a good layer of cow-mauure put on top of the drainage, which is most important, care being taken that it does not come into contact with the roots. This provides the cool, moist bottom Christmas Roses are so fond of. After flowering, mulch with leaf-mould and well-rotted manure, and in dry weather give ample supplies of water, alternated with soot and manure water. Divide the clumps and plant as soon as possible after flowering in good turfy loam and leaf-mould made firm.—J. C. PRESTON, *Tabley, Knutsford.*

Trifolium uniflorum.—Few of the Trefoils are so deserving of introduction to the garden as this, which appears to have dropped out of cultivation and which I do not find in the catalogues of the present day. It was introduced from Syria 116 years ago, and has probably been sacrificed in the wholesale banishment of so many hardy flowers at the time the bedding system was in vogue. As a plant for the alpine-house it ought to command attention, and I believe it is hardy in a dry position. As seen in one of the houses at the Edinburgh Royal Botanic Gardens, Edinburgh, the other day, it was very beautiful. The trifoliate foliage is prettily marked with brown on the green ground, and the flowers, which are purple and blue, are large and raised well above the trailing foliage.—S. ARNOTT.

The Scarlet and Poppy Anemones.—Looking at groups of *A. fulgens*, happy in meadow turf where they have been for some years with no care or disturbance, I thought of the many years that had been wasted with the Poppy Anemone (*A. coronaria*) and its numerous forms, double and single, not one of them half so good as the wild scarlet plant. At one time long lists of the double forms were sent out and the varieties labelled and grown without any good results. The mixed forms of the Poppy Anemone are showy, but not always good in colour, and in a border where they get better soil than *A. fulgens* has in the Grass they are a poor, ragged lot. Near the sea and in open soils, as in Ireland and Normandy, at Caen, they are free and hardy. In my cool, heavy soil they are not hardy, and rarely survive the winter, whereas *A. fulgens* is really hardy.—W.

The Scarlet Windflower (*Anemone fulgens*).—This has been in bloom for several weeks and is now reaching its highest point of beauty. When planted in rich, made-up soils it gradually disappears for some reason, but in meadow Grass it not only survives year after year but increases freely. The roots are planted during the autumn and winter, when the turf is lifted with a spade and three or more roots, at about 1 foot apart, put in, when the sod is replaced. In the Grass the Scarlet Windflower has few rivals at this season of the year; indeed so satisfactory is it naturalised in this way that its numbers have been considerably in-

creased of late. Established groups are gradually increasing into little colonies, which are in some instances intermingled with Daffodils and Grape Hyacinths. Once planted no further care is necessary. This Anemone should be more used in open woodlands, on sunny banks, in pleasure grounds, orchards, etc. Indeed, any position having a south-west exposure, and not of a boggy nature, will suit it. The flowers have a large blue-black boss in the centre, which serves to enhance their beauty when fully open. The flowers, freely produced on slender stalks, each 1 foot in length, even in the Grass, are very useful for cutting. There is a remarkably beautiful form with broader petals and larger flowers which comes from Greece.—E. M.

Cydonia Maulei.—This is the dwarfest of the Quinces and very useful, as it is equally at home in a mass in the front of the shrubbery or grown in a bed on the outskirts of the lawn. Moreover, it is worth growing, for its golden, fragrant fruits make an excellent jelly; in fact, some people consider that they are better than those of other Quinces for that purpose. It is usually about 2 feet in height, forming a spreading bush sometimes 5 feet or more across. The flowers are orange-red in colour and borne freely from the previous year's wood. There is a variety, *alba*, with dirty-white flowers, which is much inferior to the type in general beauty, but this cannot be said of *atrosanguinea*, with large, blood-red flowers, and which, if anything, is more free-flowering than the type. *Leichtlini* and *superba* are other forms which closely resemble the last-named. Another variety is *Sargenti*, a particularly dwarf form which might find a place in the rock garden. *C. Maulei* was introduced by Messrs. Maule, of Bristol, about forty-five years ago. It does well in light, loamy soil, and can be increased by seeds or by division. In many respects *C. Maulei* might be looked upon as a dwarf form of *C. japonica*, but it flowers more satisfactorily in the open border than that species, and is distinct in other ways. It blooms from early April to late May.—D.

Primula rosea.—In your issue of March 25th "An Amateur of Hardy Flowers" discusses the treatment of *Primula rosea*. It grows very well here in running water, and the earliest blooms come on plants which grow on a ledge of millstone grit over which a small stream flows summer and winter. I do not understand the suggestion that soil should be brought up round the crown. These plants stick up on a dense mat of roots out of the mud, and in some cases the mud is nearly all washed away by the stream, and I found no tendency to rot off. The roots get so thick that it is very difficult to divide them. My object in writing is, however, to point out the merits of *Primula rosea* as a bowl plant for winter flowering. I took one clump indoors during the last week of January when the flowers were beginning to show red. The second week in February it began to bloom, and has continued seven weeks in flower. Another clump was taken in during the blizzards of February, and it has now been flowering four weeks and looks good for another two at least. The plants are simply put into a bowl of water. The plants have the great merit of not growing straggly and floppy, even after six weeks of only the light of a room-window, but, of course, the flowers do not develop quite so good a colour as when grown in the natural way. My first plant has now gone back into the mud, where I hope it will recuperate during the next ten months.—L. J. ROGERS, *Westwood, Leeds.*

VEGETABLES.

BRUSSELS SPROUTS.

VARIOUS dates are chosen for sowing this important vegetable. Seeds may be sown outdoors during March and April, and these will produce good crops in due course. Some will choose a small frame, or even a handlight, and in this plants are forwarded for spring planting. Requiring Sprouts fairly early in the autumn, I almost invariably sow a portion of my seeds on a gentle hotbed in late February, giving air freely as soon as the seedlings are above the soil, the lights in fine weather being entirely dispensed with. The plants, when strong, are planted direct into their permanent quarters, for the custom is to set apart a plot that has been cleared of some other crop in time for the land to be manured, deeply dug, and pulverised by the weather. That the land shall not be standing idle in the interval it may be marked for the rows of Sprouts, the intervening spaces being cropped with Lettuce sown or planted, or with Radishes. It would be possible to sow in single drills in these intervening spaces Cabbage seeds for autumn use, early Cauliflowers, salad Onions, or any other quick-maturing crop that would be cleared before the Sprouts required the whole space. Much, however, depends on the width apart that is allowed. Of course, it is possible to grow a crop of Potatoes on the ground, planting the Sprouts between them. In this case not less than 30 inches must divide the rows. In strong ground 3 feet apart for Potatoes would not be too much. I have now for some time discontinued growing Potatoes as a companion crop, because of the difficulty of cleaning them without injuring the Sprouts. When planting Sprouts as an independent crop I allow 2 feet between the plants and the rows, and in this way the ground becomes fully occupied.

I always sow some seeds with the early Broccoli, Cauliflower, Cabbage, Leeks, and others of kindred nature, and these, being later, are planted for succession as ground becomes vacant. As a rule, these are short-stemmed compared with the frame-sown plants, and, of course, do not give quite the same amount of produce. At the same time, in small gardens where there is not an early demand, these outdoor-raised plants are most serviceable. In dealing with intercrops it is well to get these sown or planted as early in the season as possible, so that they have plenty of time to grow ahead of the Sprouts. Autumn or early glass-raised Lettuces can be planted at any time previous to the putting out of the Brussels Sprouts. I have cut many hundreds of summer Lettuces from the Sprout quarter without detriment.

In the matter of variety I have a distinct preference for Sutton's Dwarf Gem, of dwarfer growth than some of the "exhibition" stocks. One named Covent Garden Favourite is also dwarf. Veitch's Paragon I used to favour, because it was dwarf and gave good, firm buttons. Cambridge Champion was once boomed because it bore large Sprouts, but I think that now the small, firm Sprouts are preferred. The Wroxton is a favourite with many.

It is strange that in cottage gardens the owners quite early in the season cut off the tops of the Sprouts without any reason for so doing. Cutting the head off, naturally removes much immature growth that would develop with the advancing weeks of winter. The removal of the heads, too, has a tendency to force the buttons open. In late winter it is often possible to find

nice, close buttons clustering in the head when there are none below, and it is well to remember that, hardy as Brussels Sprouts are, the plants do sometimes feel the pinch of wintry weather. Leave the heads untouched until February at least has somewhat advanced, and when Cabbages, Savoys, etc., are getting scarce the Sprout tops come in every useful.

Wills. W. S.

NOTES AND REPLIES.

Planting Rhubarb.—This crop, from the great weight of its produce, quickly exhausts the soil; therefore it is not desirable to let it stand too long without removal, as plants that have been for some time undisturbed are liable to produce flowering shoots, which, even if cut out as soon as they make their appearance, interfere with the growth of the edible stalks. It is not a good plan to disturb the whole plantation at once, as this stops the supply for a time. If some of the outside crowns be severed from strong established stools with a por-

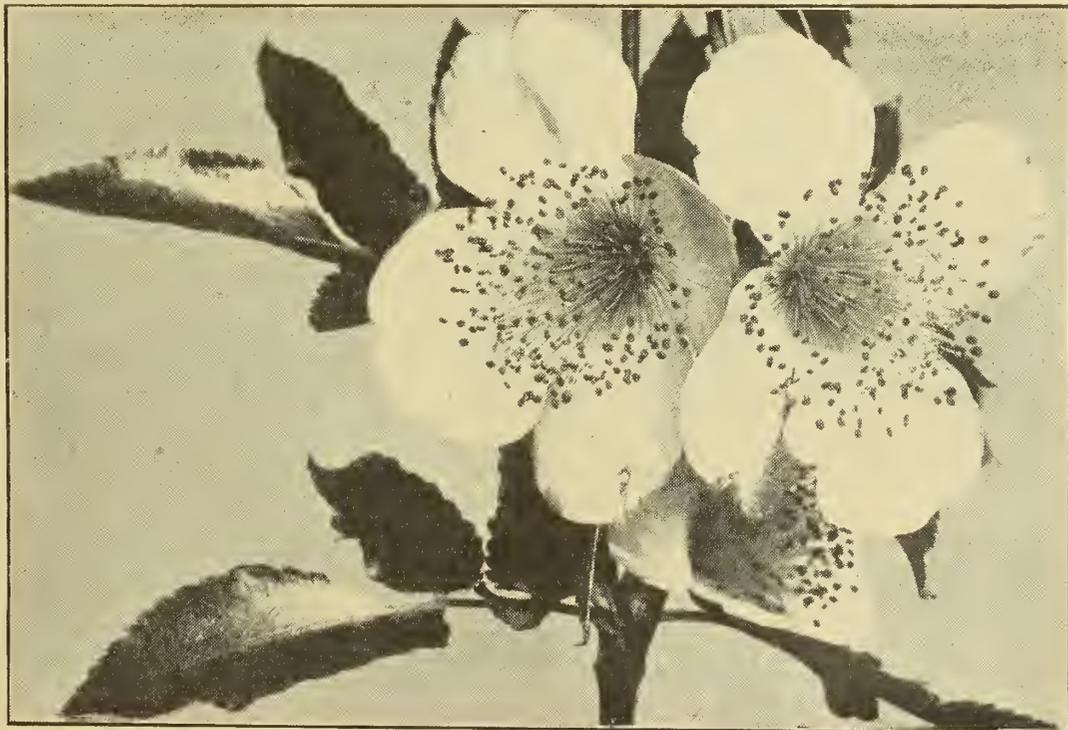

the glass. When only a few plants are wanted, suitable shelf-room is easily found within a few inches of the glass, but when plants by the thousand are required to plant several houses an arrangement of wire supports to suspend from rafters or sash-bars can be managed. I have often found it necessary to fit up a temporary stage or platform with boards, which are easily moved from place to place. The importance of light is everywhere recognised, especially when the plants are young and weakly.—E. H.

The Globe Artichoke.—I have frequently seen many inferior plants of this in gardens, and in others I fear the culture is at fault. I have grown all the varieties I could obtain, and some are almost worthless. I like the Large Purple and the Large Green Globe when good strains can be obtained. It is not desirable to rely always upon seed. For years I had suckers sent me early in the year from France, from a noted grower, as I could not get plants from seed in this country of

TREES AND SHRUBS.

EUCRYPHIA PINNATIFOLIA.

ALTHOUGH here and there one meets with good examples of this Chilean shrub, it is less frequently found in gardens than could be wished. This is, doubtless, due to the fact of its being difficult to establish, especially when, as is frequently the case, it has been propagated from layers. In a mild winter it is practically evergreen, but when severe frost is experienced the majority of the leaves fall by the middle of January. The flowers appear in July and August, and are suggestive of a large, shapely single Rose. The petals are white, and there is a central mass of golden stamens. It succeeds best in a moist climate in damp but well-drained ground. The south-west counties of England suit it admirably, whilst good examples are reported from Ireland. In Cornwall a very fine specimen is to be seen. Seeds are ripened in this

A flowering shoot of *Eucryphia pinnatifolia*.

tion of root each, and planted now two or three together, and allowed to attain a maximum of strength, not gathering from them this summer, they will bear strong stalks next spring; or roots that have been forced through the winter planted now and permitted to regain strength through the summer will succeed. As Rhubarb is a deep-rooting, gross-feeding plant, in all cases it should have rich deep soil, and if it be of a heavy, retentive nature some old exhausted tan, leaf-mould, wood-ashes, or sandy road-drift, if such can be procured, all mixed together with 6 inches or 8 inches of good rotten manure, should be mixed with it, trenching the ground 2 feet or 2½ feet deep, planting 6 feet apart each way. A crop of Radishes, Spinach, or Lettuce may be had off the ground between the rows before the Rhubarb makes sufficient growth to interfere with them. Existing beds of Rhubarb will be much benefited by heavy drenchings of manure-water during the next two months.

Advantage of light.—When raising Tomatoes early in the season it is important for the young plants to be near

anything like the quality. In some gardens these plants, in spite of protection, winter badly. Though from seed sown now—March—one can form new beds, in low-lying districts and badly-drained soils, frequent plantings are necessary, indeed it will be found advisable to make new plantations every three years, as after that time the heads become less succulent and the plants much weaker. I have frequently gained time by sowing seed in 5-inch pots in spring and thinning to the three strongest. Seedlings raised under glass, and when ready planted out in deeply-dug, prepared land, give a good return the following year.—M. F.

Clubbing in Cabbage, etc.—In some soils this is very troublesome. The one I have to deal with causes much thought to bring a crop through without many affected plants. Anything that will assist the crop is helpful. I have found nothing to equal soot and poultry manure. Last year these were most helpful with Cauliflower, Brussels Sprouts, etc. When the plants were coming into the rough leaf the first dressing was given, scattering it among the plants and giving another dressing in a fortnight. When planted out a coating is put round each plant when established, with another dressing in about a month.—J. C. F. C.

country, and plants raised from them appear to succeed better than those raised from layers. Layered branches take a couple of years or so to become well enough rooted to sever from the parent plant. Cuttings have occasionally been rooted, but not in any great quantity.

NOTES AND REPLIES.

The Star-flowered Magnolia (*Magnolia stellata*).—Few shrubs are more beautiful than this when seen at its best, for every branchlet is then clothed with glistening white, fragrant, star-like blossoms, each really semi-double in character. It is a native of Japan and has been grown in our gardens since 1877, although it only became really well known about twenty years ago. Often met with between 6 feet and 8 feet in height, it is over 12 feet high in some gardens, a particularly fine example existing in the gardens at Abbotsbury Castle, in Dorsetshire. It is, however, always met with as a bush, thereby differing from *M. Kobus*, a good-sized tree from Japan, with leaves like those of *M. stellata* and similar-sized white flowers, except that in

M. Kobus there are but six petals instead of twice or thrice that number, as in M. stellata. The flowering time is late March and April, and on that account it should be planted in a sheltered position, for if exposed to cold winds or frost when in flower the petals are soon injured. Plant in well-drained loamy soil and place a little peat or leaf-mould about the roots at planting time. Propagation is usually effected by grafting it upon stocks of M. Kobus, but it can be raised from layers. There is a variety with rose-flushed flowers, but it is not so beautiful as the type.—W. K.

The Mountain Pine (*Pinus montana*).—Although the ordinary form of this does not grow large enough for use as a timber tree, there are varieties that grow from 50 feet to 100 feet high and form a considerable portion of the forest vegetation of certain parts of the Pyrenees and also of a restricted area on the Italian frontier of the Swiss Alps. The chief of the tall-growing forms, known as *P. m. uncinata*, is being tried in some parts of the Scottish Highlands under forest conditions. Its value would appear to be greater, however, for shelter than for timber, for at high elevations it may grow large enough to protect young trees of greater commercial quality which cannot at present obtain a good start in bleak and exposed situations and at high elevations, but would grow well once they became established. The dwarf form of *P. montana* is, however, well worth planting for cover either in park or garden, or on hillside or moorland, for it harmonises well with the natural shrubby vegetation of the wilder parts of our country, is a good evergreen, and makes excellent cover for game. Moreover, it can be used with effect with double-flowered Gorse and common Broom for clothing bare places where the soil is thin and poor. It should be planted permanently when very small and young, for, as is the case with other Pines, trees two or three years old become established more quickly than older specimens.—D.

Spiræa arguta.—Of the early-flowering Spiræas, this is, in the open ground, one of the very best, while it is equally desirable for flowering under glass earlier in the season. It is of a very pleasing habit of growth, with slender, gracefully-arching shoots. Some of the Spiræas fail at times to give satisfaction by reason of the blossoms being injured by spring frosts, but this can be relied on. The pure white flowers are borne in clusters on the upper part of shoots made the previous year. When at their best the entire plant is quite a mass of white, which is very noticeable against the somewhat dark-coloured bark of the stems. It reaches a height of 6 feet to 8 feet, and a well-furnished specimen will be as much in diameter. For flowering under glass it may be potted up in autumn, just as the leaves are about to drop, when, if plunged out-of-doors and kept watered, the roots will take possession of the new soil before they are taken under glass. *Spiræa arguta* is of hybrid origin, but there is some doubt as to its parentage, though *Spiræa Thunbergi* is regarded as one parent.—K. R. W.

Linum Pallasi.—Under this name there is a fine yellow Flax cultivated in one of the cold-houses at the Edinburgh Royal Botanic Garden. It is after the style of *L. flavum* and *L. arboreum*, and bears at Edinburgh the reputation of being one of the best of its class. "The Index Kewensis" refers *L. Pallasi* to *L. tauricum*.—S. A.

"The English Flower Garden and Home Grounds."—New Edition, 12th, revised, with descriptions of all the best plants, trees, and shrubs, their culture and arrangement, illustrated on wood. Cloth, medium 8vo, 15s.; post free, 15s. 6d. Of all booksellers or from the office of GARDENING ILLUSTRATED, 63, Lincoln's Inn Fields, London, W.C.

GARDEN FOOD.

MEATLESS CURRIES.

WHERE there is a garden, especially one in which there are facilities for growing small saladings under cover, it is economical to have at least two meatless dinners a week. Vegetable curries are nice in cold weather, but, as a rule, the English idea is to mix curry-powder with the gravy until it is very hot, and serve the dish with boiled Rice. Curry may be quite mild and yet be delicious. The flavouring of a mild curry is not disliked by children, and it adds to the variety of the dishes that can be made out of vegetables. The preparation of curry requires some care, as it is the cooking and frying of the gravy which make or mar the whole.

CABBAGE CURRY is delicious. Take a Cabbage with a firm, hard heart, wash and cut it into quarters, removing all the loose leaves. Slice finely after cutting out the whole of the stalk. Melt a dessertspoonful of bacon fat in a good-sized saucepan, place the sliced Cabbage in this, and fry gently, stirring occasionally until the Cabbage looks rather transparent. Slice two moderately large Onions in rings, peel and chop two large sour Apples, add these to the Cabbage, and continue frying the whole until it is nicely browned. Sprinkle into the saucepan a dessertspoonful of good curry-powder according to taste, a tablespoonful of flour, sufficient salt, two lumps of sugar, and the juice of a large Lemon. Fry for ten minutes longer, stirring all the time, then add two cupfuls of hot water or vegetable stock. Simmer for a few minutes until well blended, then turn into a jar. Stand this in a pan of boiling water and cook for an hour or longer. Just before serving pour two tablespoonfuls of boiling milk upon a tablespoonful of desiccated Coconut. Leave for five minutes, then stir the Coconut and milk into the curry, and serve at once with boiled Rice.

POTATOES are very good curried by the above recipe, as also firm Brussels Sprouts. Perhaps the best way to serve Brussels Sprouts is to boil them and toss them in a little cream or butter and serve on squares of buttered toast. Carrots and Parsnips will also curry nicely, and there is no end to the various vegetable curries that can be made with a little trouble and forethought. H. T. C.

NOTES AND REPLIES.

Apple Newtown Pippin.—It is only recently I have made the acquaintance of this popular Apple. I have not had occasion to purchase, because the garden furnished all I needed. The Newtown Pippin is undoubtedly a good Apple, and it is to be regretted that it will not grow in this country. The fruit imported now in such a fresh, plump state does not compare with our own in normal times. Some of our own standard sorts compare favourably with it, and even in its present season the Newtown is not very far ahead of a good sample of Sturmer Pippin, which seems to be overlooked by many private gardeners. Unlike the Newtown, the Sturmer is a hardy, free-fruited, and healthy tree, adapted to our variable climate. Adams' Pearmain, Bess Pool, Claygate Pearmain, Reinette de Canada, and Dutch Mignonne are each very good Apples. It is, of course, more or less true that purchasers of these imported Apples have not a fruit garden of their own of any size, therefore those who are dependent on their own home supply must look to those sorts that will thrive and crop freely and regularly in their own gardens. The secret of having plump Apples in spring is a cool

store and gathering as late as possible. If they are not carefully gathered and cool-stored, then they shrivel before their season has actually commenced, and, when shrivelled, their value has gone. I have recently tasted some Surrey-grown Sturmer Pippins that are as firm, juicy, and full-flavoured as to place them in competition with the best of these imported fruits.—W. S.

Celeriac.—Good Celeriac should be plentiful in all country gardens, but it is not always made good use of by the cook. Such soup and dishes are often spoiled by over-spicing. Pepper, Mace, etc., are better left out. The very large-rooted kind of Celeriac is not the best.

CELERIAC SOUP.—Scrape a root or two, according to size, of Celeriac, wash it well, and cut it into slices. Cut a large Onion and a Turnip in the same way and put all into a stewpan containing 1 oz. of butter; cover them closely with a large piece of greased paper and let them cook gently for fifteen minutes without becoming in the least brown. Stir in two tablespoonfuls of best flour, and when it is smoothly mixed with the fat pour in by degrees, stirring quickly all the time, a pint and a half of water. As soon as it has boiled and thickened, lightly season. Draw the pan to the side of the stove where the vegetables can simmer gently, and when they are quite tender, pass them and the liquid in which they were cooked through a sieve and add one and a half pints of milk. Make the soup hot, letting it just reach boiling point, and serve it with some dry, grated Parmesan cheese for those who like cheese.

Excelsior Haricot.—This is a small variety of Haricot, in shape like the Flageolettes, but rather fuller. It is also somewhat different in colour, being browner, although a green shade is noticeable. Our sample was from Messrs. Barr, Covent Garden. We steeped the Beans twelve hours, then placed them in clean, cold water, brought them rapidly to the boil, and let them remain at a gentle heat until soft. We added a little "nutter" (vegetable butter) to them while cooking, as some form of fat seems necessary to make Beans palatable. Served with roasted Potato and a little cheese savoury and breadcrumbs they answered excellently. They have a pleasant flavour and are easily digestible.

Keeping Ribstons.—When I sent you two or three specimens of my Ribstou Pippin early in December last I mentioned that when in past years I had stored them on shelves they had shrivelled after the turn of the year, and that this year I was trying the experiment of storing them in a flour barrel, each in silver paper. The experiment has been quite successful, as you will see by a couple sent you herewith. About 3 per cent. or 4 per cent. of them only have gone rotten. I am not quite sure whether they would not have been better without the silver paper, which has become damp, but perhaps the damp has been absorbed by the paper and saved the fruit.—J. D. THORBURN, Upton Cross, Chester.

The Potato Onion.—The fine examples of this shown in a recent issue were sent me by Lady Moore from Glasnevin. The warm Irish soils seem to suit this interesting Onion better than some of our heavy soils, and the Onion finds favour with the cook, and is said to be a cause of the merit of the Irish stew, often, it is said, misunderstood by the English cook. The flavour is milder than that of the common Onion. Of its origin little appears to be known.—W.

—I was pleased to see such a fine illustration of the Potato Onion in the issue of April 8th, the figure on page 185 giving an excellent idea of the variety. The Potato Onion can be recommended as a most excellent keeper, remaining hard and fit for use after the ordinary variety begins to turn soft and give indications of growth. It is worthy of more extended cultivation, and might—probably would—succeed in gardens where sown out. Onions fail owing to the attacks of the grub.—W. McG., Balmac.

PLANTS AND FLOWERS.

ROOM AND WINDOW.

THE TAURIAN SCILLA AND THE BAYONNE DAFFODIL.

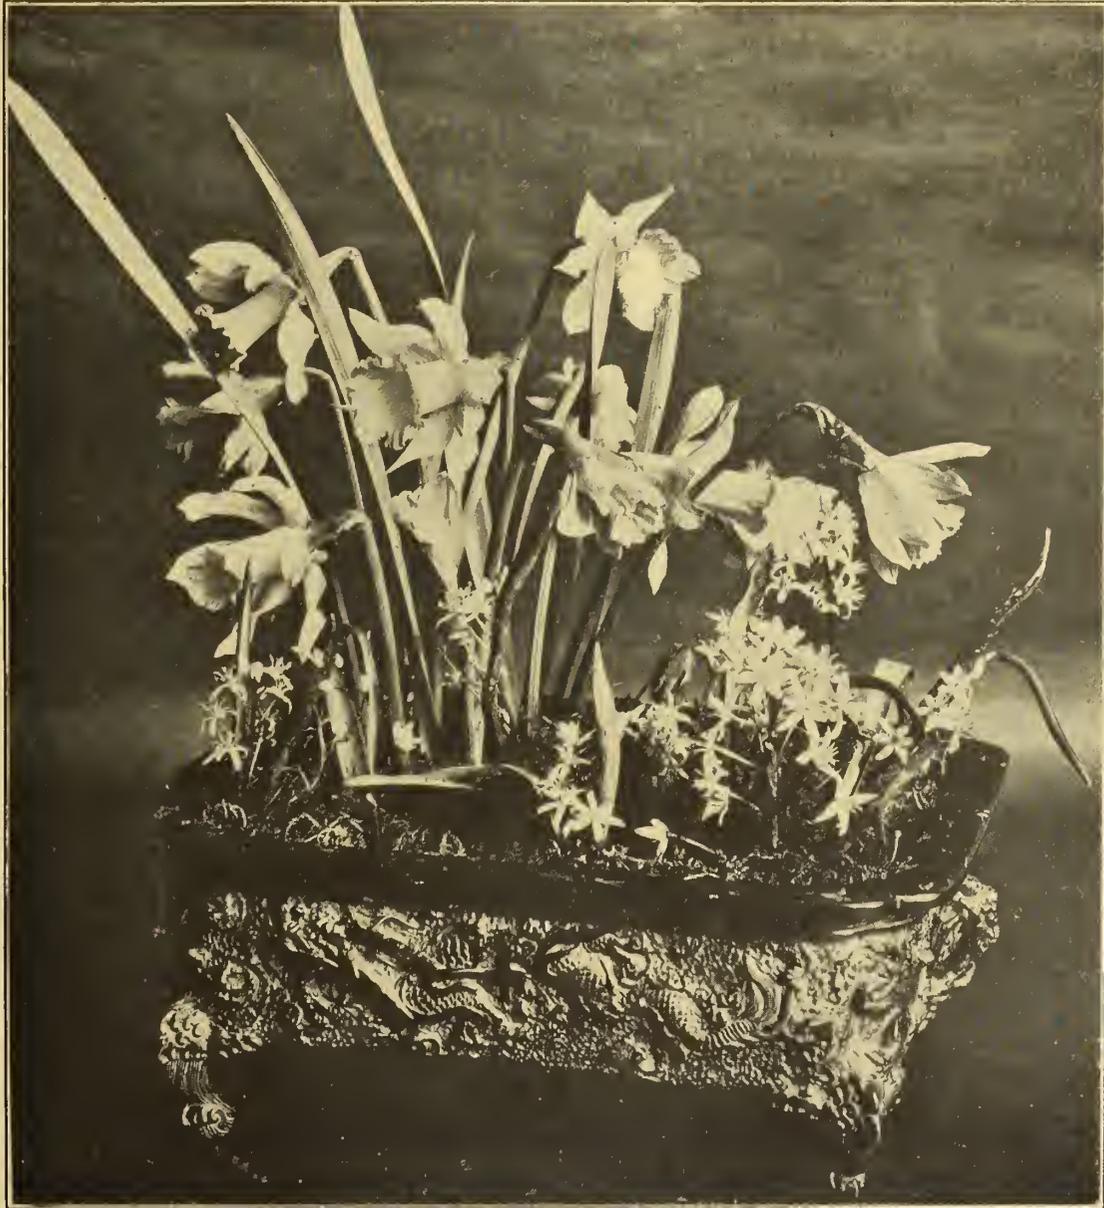

THESE are among the plants one cannot well do without. The Taurian Scilla sometimes called a variety of *S. bifolia*, and erroneously so from a garden point of view, is an early and charming flower, not to be got in the trade so freely as some others. It is much bolder and of a richer

order. Roots of Pansies and other hardy seedlings can be cheaply obtained in the market, and Sweet Peas may be purchased in the shape of seeds or small plants, while a lot of brightness may be obtained from Nasturtiums sown now.—E. H.

Fine-foliaged plants in rooms.—At this dull time of the year those who have plants in the windows of rooms sometimes wonder what they can do to assist in their well-being. Such plants may include *Aspidistras*, *Aralias*, *Ficus elastica*, or even Palms of the hardier sorts, and when gas is used, that and the heat from fires sometimes injure them. Much good can be done in such cases to those broad-leaved subjects by sponging the foliage with tepid soapy water at frequent intervals, afterwards washing them over with clear water. It is of advantage, too, to change their position occasionally. In all cases, just at pre-

Caladiums, and feathery Palms were all useful, and when these were not available we could find suitable things in cooler houses among Ferns and bulbs. Of course, there were fruiting plants, including the small *Otaheite Orange* laden with fruit. For a change I have sometimes with advantage used pans of *Selaginellas* as a base for flowers.—E. H.

Flowers for the rooms.—There are now the early-flowering bulbs in much variety, white and red *Azaleas*, *Primulas*, *Cinerarias*, *Arum Lilies*, *Lilium longiflorum*, and plenty of Ferns, Palms, and other fine-foliaged plants that will keep fresh a long time if carefully managed as regards watering, which means they must be kept reasonably moist at the roots and the leaves washed with a soft, damp sponge occasionally to remove dust and other impurities. Of course, there should be other things in re-

The Bayonne Daffodil and the Taurian Squill in a vase.

colour than the ordinary *S. bifolia* of France. It has its place here around some of the Bayonne Daffodil, the earliest and the best of the early Daffodils. The Bayonne Daffodil grows on the Grass better than it does in the garden soil.

W.

NOTES AND REPLIES.

Window-boxes.—I suppose window-boxes and other decorations will in some cases be stunted in consequence of the war. That will be a mistake, I think, as there is nothing like useful and interesting work to enable us to see the bright side of things. There are many cheap plants to beautify boxes and small beds and borders. *Mignonette* and other annuals may be sown when the soil is in good working

sent, no excess of moisture ought to be supplied.—KIRK.

Epimedium leaves for winter.—The bronzy leaves of the *Epimediums* are valuable for winter decoration. It is not advisable to crop the plants too hard, as the old foliage helps to protect the young growths, which are sometimes liable to be injured by late frosts. The best of the *Epimediums* for this purpose are the larger-growing ones, such as *E. colchicum* and *E. perralderianum*, both of these having good stems and bold, handsome, well-coloured leaves. Associated with Rose and other fruits, they are pretty for table decoration when flowers are scarce.—ESS.

Plants for table decoration in winter.—In the past we depended largely upon the stove or other warm-houses for plants to decorate the table. *Pandanus Veitchii* was good, but the spines on the leaves were sometimes troublesome. *Crotons*, bright-leaved *Dracaenas*,

serve, as where gas is burnt there must be a change sometimes.—E. H.

Treatment of seedling Abutilons (*Inquirer*).—You have only to grow the plants on in much the same manner as *Fuchsias*, affording them plenty of light, air, and moisture, and they will probably all bloom in the autumn or early part of the winter. When the tiny seedlings have formed one proper leaf transfer them singly to 3-inch pots, using a mixture of equal parts of loam and leaf-mould, with some sand. Keep them moist and shift them on into larger pots until those from 6 inches to 8 inches in diameter are reached about the end of August. For this last potting the soil should be somewhat heavier, consisting chiefly of good fibrous loam, and it should be made quite firm about the roots. Give some weak liquid-manure once or twice a week when the pots are full of roots.

GARDEN PESTS AND FRIENDS.

AMERICAN GOOSEBERRY MILDEW.

THERE is no doubt that the above pest is spreading throughout the country. Unfortunately, in new localities it is seldom recognised until a considerable area has been infected. Enough has been published in leaflets and also in the horticultural press to enable gardeners and those used to such descriptions to identify it, but by far the greater number of those who grow Gooseberries never read anything concerning them. Numbers of cottage gardens have old, uncared-for bushes badly diseased, yet as long as they bear a crop of fruit they are permitted to exist, a source of infection to the whole district. Not only is the disease wind-borne, but the kindly-meant gift of cuttings to their friends often carries the disease miles further, and too often establishes a new infected area. It is not the cottagers' fault. They cannot be expected to deal with it satisfactorily. If the disease is noticed at all they usually conclude that the bushes have got "some kind of blight," and a little mildew more or less is not an uncommon occurrence. The Government have enough on their hands without making a house-to-house inspection, for although this might be possible in towns and allotments adjacent thereto, in the country the distance to be travelled would be serious. Landowners might do much good by instructing their gardeners to inspect and report on their tenants' bushes, and help them to obtain young stock from uninfected sources. Again, in the case of one or two infected cottage gardens on an estate it might be possible to destroy the bushes at once, allowing no host plants for a few years, eventually replanting with clean stock from the home nursery or elsewhere. Under the present law, the Board of Agriculture, when notified, sends an inspector—sometimes months afterwards—who insists that all shoots must be tipped as soon after August as possible. A recommendation as to spraying with sulphide of potassium is also given, though this does not appear to be compulsory.

The market-grower who grows Gooseberries cannot afford to lose his livelihood, so he probably carries out the instructions of the Board more or less thoroughly, and gathers his crop green. Even if the fruits have been sprayed he may be able to wash them clean enough for sale. But the private grower wants not only green Gooseberries, but ripe ones in due season, and spraying in summer is liable to spoil ripe fruit entirely. Indeed, the problem of ridding his garden of this pest and of continuing to supply the table with Gooseberries each season is a difficult one, especially in comparatively small gardens.

Those who have the space to plant a plot at a safe distance from the infected area should do so, and destroy the old plot as soon as the other comes into bearing. If a sufficient number of young Gooseberry bushes is planted a good crop of Gooseberries can be had the second summer after planting. Indeed, I have often seen an excellent crop the first summer. It is only necessary that sufficient bushes should be planted to compensate for their small producing capacity; the quality of the berries is usually first-rate. According to the leaflet No. 195 issued by the Board of Agriculture, "The ultimate and only sure remedy where a plantation has been badly attacked is early pruning for a series of three or four years," viz., the removal of all diseased tips in August and September each year. Can any grower be absolutely certain that he has cut off and

picked up every diseased tip from a number of bushes? If not, the remedy is by no means "sure." It would appear that the only "sure" remedy for the owner of the small garden is to destroy his Gooseberry bushes and forego home-grown Gooseberries for three or four years until the disease has died out in his garden, and then replant from a clean source.

J. COMBER.

OUTDOOR PLANTS.

TUBEROUS BEGONIAS IN THE FLOWER GARDEN.

It may not be generally recognised that a very interesting and enduring display can be made outside with tuberous Begonias through the summer at a minimum of labour and expense, a fact worth noting in a season like the present, when both are a serious consideration. Instead of starting them in heat the tubers can be planted

Cordyline australis at Ashbourne, Glounthaune, Cork. (See p. 207.)

in a cold frame from which frost can be excluded, and brought along gently until planting time. Any old potting soil will do for the purpose, and they can rest within an inch or so of a solid ash bottom, so that they can be lifted without injuring the roots. Where opportunity has offered for seed-sowing and selection there is generally a good stock of tubers on hand, and in singles they should be somewhat in habit of which *B. Worthiana* is a type, with rather small, erect flowers rather than big, unwieldy blooms too heavy for the stalk and likely to be prostrate after a storm. Doubles also should not be too large; not larger, for instance, than in sorts like Major Hope (pink) and Lafayette (scarlet), otherwise a lot of staking and tying is necessary, and even if this could be done, which is hardly likely, the flowers would not show to the best advantage. From the time the young growths make their appearance until planting, a watch must be kept for the minute thrips that,

if allowed to make headway, will greatly disfigure the foliage. Begonias show to the best advantage alike in the display of flower and proper development of the plants when set out singly or in thin groups on a carpet of dwarf plants. If opportunity does not offer for striking tender things, hardy subjects will have to be utilised, and, indeed, answer the purpose equally well. For scarlet and pink kinds one of the best dwarf things is a white Tufted Pansy like Seagull, which, if a little special attention is given, will remain in flower all through the summer. The little Violetta is sometimes used, but of the two I prefer Seagull. Failing the Pansies a very good substitute is *Antennaria tomentosa*. This live carpet, as represented by Pansies or *Antennaria*, is preferable to mulching the ground around the Begonias with Cocoa-fibre. E. B. S.

Hardwick.

AMONG THE HARDY FLOWERS.

SCILLA SIBIRICA.—I like the blue form of this better than the white one, either for the open garden or in pots for the house. Is there a pink variety of *S. sibirica* in existence? I know a pink variety of *Scilla bifolia*, but not of *S. sibirica*. I plant 2 inches or 3 inches deep, which I find quite enough.

CROCUS TOMASINIANUS.—This is a pretty and useful *Crocus*, a few corms of which a friend who has grown it for some years gave me. Its sapphire-lavender flowers are pretty. It blooms early in March, is very hardy, and stands the storms of the time much better than some of those with larger flowers. My friend has several varieties, one with deep purple flowers, another with lilac ones, and a rarer one still with white flowers.

COCKBURN'S PRIMROSE.—There is much that is puzzling to an amateur in the conflicting accounts of the behaviour of *Primula Cockburniana*. Most folks assure us that it is only a biennial, others say that it is a perennial, and others declare that it seeds and sows itself so freely that they never trouble about renewing it should it die out. One of my friends who is keen on Primulas has been collecting information from others to compare their experiences with his own. His conclusion is that Cockburn's Primrose is a biennial in all but a few places, and that it seeds best in a gravelly soil, though there it is not perennial. I am not hopeful of ever being able to retain it as a perennial in my garden. So far I have only managed to keep it until after it flowered. It is such a striking thing with its vivid orange-scarlet flowers that I would be glad could I reckon it as perennial.

PROPAGATING PRIMULAS.—Most hardy Primulas require to be propagated occasionally, either by division or seeds, and it is hopeless to expect many of them to live and be happy in the conditions so many of us amateurs give to a number of our flowers. They are not so troublesome if they are kept well top-dressed, but if they are left alone for a year or two they generally suffer. I find that the best time to divide hardy Primulas, including Polyanthus and so forth, is just after they have flowered.

ADONIS VERNALIS.—This old favourite is just coming into bloom. Nobody can deny that the finely-cut foliage is very ornamental, and when the large, many-rayed flowers open out to the sun it is a charming plant. It prefers a rich, moist loam, but I have been compelled by the force of circumstances to cultivate it in a drier loam. I have added a little peat, and, to give it as much moisture as convenient,

have planted it at the foot of a little rockery.

THE ALPINE ERYNGO (*Eryngium alpinum*).—This has become one of my favourites. I was lucky enough to come across it in a garden where there was "enough and to spare," and was made happy by the gift of a good clump. Its possession led me into some discussion respecting its requirements in the way of soil, and I learned that in a stiff, rather clayey loam in a coldish district it never did so well as in a lighter, drier one.

AN AMATEUR OF HARDY FLOWERS.

SUB-TROPICAL PLANTING.

MANY pleasing effects may be produced in the southern parts of England by the introduction of sub-tropical plants, and where Bamboos and *Cordylines* survive,

erythrorachis, red-ribbed and highly perfumed when in flower, can be arranged between the collections of Bamboos; *Yuccas*, which thrive in rather damper soil than their appearance would warrant; *Eryngiums*, *Kuiphofias*, *Arundinarias*, *Gyneriums*, including the fine golden form so little seen in our gardens; and *Chamaerops excelsa*, which often develops, even in our climate, into a small tree. Of the *Kuiphofias* the finest and most effective are the seedlings of *K. Northia*, which appear to be hardier than the original species. *Aegle sepiaria*, an interesting shrub, with its masses of fragrant white flowers, is hardy in ordinary English winters when planted in well-drained ground. *Colletia horrida* and *C. ferox*, with their peculiar woody spines and interesting clusters of white flowers which appear in the autumn, *Fatsia japonica*, with its irregularly-

hardened off. These will be planted out in rows 1 foot apart, the rows 15 inches asunder. Of the single varieties, *La France* and *Admiral Avellan*, a large number is grown. The former, if propagated early, blooms more or less throughout the autumn and winter, and in the greatest profusion in spring. The latter blooms in the spring only, but the flowers are plentifully produced over a long period. All the young growths having a few roots attached are used for the propagation of both sorts, which are planted as soon as severed from the parent plants in a well-manured and partly shaded plot of ground and watered in. These two kinds require more space for development than the double ones, and are therefore set out 18 inches apart in the rows, which are 15 inches asunder. Until new roots are formed and the plants become established

Cordylines and Arundo conspicua at Ashbourne, Glounthaune, Co. Cork.

other species will be found to flourish, despite short, severe attacks of cold and frost. Two essentials, however, are necessary for their successful cultivation—the most favourable conditions of sun and protection from winds. The latter is of equal if not of more importance than the former as large-leaved, tall-stemmed plants or trees suffer greatly from the rending, swaying motion imparted by strong winds. The soil most suitable should be naturally friable, sandy, and well drained, thereby encouraging the permeation of heat into the ground itself.

It is a mistake to introduce too much colour, but rather develop the general impression of soft shades of green. The various groups can be formed upon a well-kept sward of short Grass.

Bold groups of *Cordyline australis*, *C. Banksi* and its beautiful variety *C. Banksi*

shaped leaves, *Eucomia ulmoides*, the cousin to the India-rubber tree, and the various forms of the taller Grasses, both green and glaucous-blue, such as the *Aira* and *Elymus*, may also find a place.

When a collection of such-like forms is carefully arranged upon a sufficiently large scale it will be found that even in the southern parts of England we are able to bring into view pictures which can otherwise only be enjoyed in warmer and more favourable climates. R. H. BEAMISH.

NOTES AND REPLIES.

Violets.—These are now over and propagation of the several varieties must be attended to. With regard to the double varieties *Marie Louise* and *Mrs. Astor*, the cuttings, as was mentioned in a previous note, had been put in. These are now well rooted and are being

water is required daily in dry weather, with an over-head sprinkling in the afternoon to act as a reviver.—A. W.

Arctotis grandis.—This half-hardy annual one rarely sees in English gardens. Being a native of South-west Africa, it requires a warm site and dry position, and may be sown out-of-doors where it is to bloom during the present month or in May. A better way, however, is to sow at once in heat, planting out in the mixed border in late May. The flowers, borne on long stalks, are excellent for cutting. It reaches a height of 2 feet, and blooms freely all the summer.—E. T. ELLIS, *Weetwood, Ecclesall, Sheffield.*

Leptosyne Stillmani.—This grows about 1½ feet in height. Sown in April out-of-doors in good soil, it will bloom in from six weeks to seven weeks if the weather is good. The large, bright, golden-yellow flowers are useful for cutting. Sow the seed thinly, and thin out the plants so that they can have plenty of room. If you want to keep the plants in bloom cut off dead flowers regularly as soon as they appear. Seeds may be sown earlier in heat, and the seedlings pricked off as soon as they are 1 inch high. Plant out in May.—E. T. ELLIS, *Weetwood, Ecclesall, Sheffield.*

CHRYSANTHEMUMS.

CHRYSANTHEMUM NOTES.

RECENT unusually wintry weather has necessitated keeping the plants warmer than we generally do in March, but by the time these notes are in print they should be out of the greenhouses and placed in frames where the standing ground is cool and moist. These conditions tend to a strong, healthy growth, free from insect pests. Here also ventilation is an easy matter, and we can allow abundance of air in favourable weather, besides readily protecting at night from frost. Subject to the latter and cold, cutting winds we should endeavour to give open-air treatment, because, after all, Chrysanthemums are pretty hardy. Each morning one likes to sprinkle the leaves overhead after each plant has been attended to at the roots. At this time of the year the one look through should carry us through the day, as it is advisable that when closed for the night the leaves as well as the roots should not be too wet.

REPORTING should claim attention. Those plants in small pots may go into the 5-inch size, and, of course, if there be any what we will call late-rooted cuttings to deal with these should be potted singly. Soil composed of rotted turf sifted rather fine forms the chief part of the compost, and to each bushel of this may be added a peck of leaf-mould with a sprinkling of silver sand. The addition of manure in early stages may prove harmful, that is, if the same is not old and quite rotted, and certainly artificial manures would be. In potting, the soil may be pressed firmly with the fingers, but not rammed in with a stick as in later shifts. I have always contended that Chrysanthemums bear the better quality blossoms, all other things being equal, if each plant is allowed to grow to its natural height from start to finish, than through any system of taking the tips out of the growths. I would therefore start with one stem. This will eventually branch out, and, as time goes on, the number of branches to be trained can be managed at will. If the object be big show blossoms the number of side stems carried up is usually not more than three, and this small number is kept to until the end of the season, the whole of the plant's energy being centred in them. On the other hand, if a bushy specimen is desired, one that shall give a great number of flowers, then retain more side branches. Stopping does not help us at all, for in the first place if a plant has its top taken out the chances are that it will produce growths unequal in strength, and therefore there will be a want of shape, and in the second place valuable time is lost. A long season is required to perfect the growth, or otherwise the flowers will exhibit faults due to imperfect ripening.

EARLY-FLOWERING VARIETIES have for years had some distinguished group among them. The earliest, perhaps, was Mme. C. Desgranges and its progeny. This group, however, produced only shades of yellow and its parent white. Then there was the Gustave Grunerwald collection of "sports." This family was notable for earliness, nice flowers, but the habit of growth was poor. After this came Mme. Marie Masse and its numerous different-coloured sports. Somehow each and all of the above are now wanting in constitution, they do not grow so well as formerly, and to-day we have a distinct race more preferred, named Polly. There are Crimson Polly, Bronze Polly, Yellow Polly, and White Polly, a set that should be cultivated by all. The class has one fault, and that is not a great freedom in producing

cuttings for propagation. But, when once obtained, the plants grow freely, the habit is particularly branching and free-flowering, whilst the blossom is, in quality, surpassed by no other sorts. These varieties make capital pot plants, too, and are well worth trying thus for decoration early in September. In regard to the varieties generally there is nothing gained in raising a fresh supply of plants in heat early in the season. At this time there should be a supply of healthy cuttings, which, if rooted in cool frames, may be expected to outdistance early-reared ones at the flowering season. These outdoor kinds are worth generous treatment in the way of deeply-dug and well manured ground, and they should have an open spot in which to grow, as well as a couple of feet between each plant. Returning to plants in pots. It is not too late to root cuttings of November-flowering varieties to provide useful material in comparatively small pots for decoration or for cutting. Exhibitors also have found these late-rooted plants useful in giving just one handsome flower on each, and the plants take up but little room. As the season advances, however, it will be found easier to root cuttings of Chrysanthemums on a cool bottom—of ashes or the like—and shaded from the sun, inside a glass structure, of course. H. SHOESMITH.

Chrysanthemums losing their leaves.—I have been growing Chrysanthemums for the past few years with very unsatisfactory results. I always notice about July or August the plants lose a lot of leaves from the bottom half way up the plant. Would you please let me know the cause of this? The flowers are always very small. I would like to know at what time and how often the plants ought to be pinched?—AMATEUR.

[The loss of leaves is caused by faulty watering. During the months named we get, of course, our hottest weather, and the plants will not put up with neglect even for a day. Once they get so dry at the roots that the leaves flag, seldom do these recover—they turn yellow and eventually fall, and naturally it is the lower leaves which suffer first. Watering should be attended to as often as twice a day—morning and evening—then there would be little likelihood of trouble. Crowding the plants is another frequent cause of leaves falling, as under such conditions the plants do not obtain enough light and air. Stopping or "pinching," as the plan is sometimes termed, need not be followed. Let each plant grow to its natural height. Those who cultivate for exhibition may find pinching useful in the case of just a few varieties, but to recommend any interference with the whole lot is a mistake.]

Late Chrysanthemums.—There are, of course, varieties which naturally bloom late, but these are limited not only in quantity, but in colour. At Christmas there is usually a demand for white Chrysanthemums, and while there may be newer additions to the list, I find nothing superior to the older varieties, for cutting at least. Take, for example, Souvenir de petite Amie, Moonlight, and Boule de Neige of the older sorts, Nellie Pockett, Elaine, and Julian Vallet of more modern date, and these grown in bush form will give plenty of flowers for cutting. In yellows, Noces d'Or, Mrs. Greenfield, and W. H. Lincoln cannot be surpassed. If an addition might be made to these three it is Phœbus, cuttings of this struck in April and grown naturally giving good results in late December. A good chestnut-red is Sarah Owen, and General Nogi is an excellent late Chrysanthemum. Both of these make ungainly bushes, but flower well. The colour of General Nogi I would describe as a pale lavender.—W. McG.

ROSES.

POT ROSES.

THE earlier batches of pot Roses will now need some extra nourishment to enable them to produce first-class flowers. Newly-potted Roses are excepted, for if these were started in good compost they will find as much nourishment as they need until the roots have occupied the compost. Only when the pots are full of roots should liquid manure be used, or it will sour the soil before the roots can assimilate it. For the same reason, too, we see the urgent need of providing good drainage. Animal manures in liquid form are somewhat offensive when used under glass. Soot-water is quite safe. The soot should be tied in a bag and steeped in water, applying it when about the colour of weak tea. Guano may be given to well-established plants, and will have very beneficial effects upon growth and bloom. A safe liquid is made by using 1 oz. of guano to a gallon of water. Artificial manures are best applied on the surface, about a tablespoonful to each pot. This is then watered in and a sprinkling of potting soil placed over the manure. Each subsequent watering will then take a portion of the food down to the roots. Bone-flour is a valuable plant food that is not used so much as it deserves. It may be applied in a similar way. Such dressings need only be applied about once a month, the ordinary watering doing the rest, but liquid manures must be given twice weekly.

Those who do not mind the unpleasant odour will find that liquids made from animal manures are superior in their effects to any of the foregoing. The manure is placed in a bag and steeped in a tub of water for a few days, being given fairly strong and as clear as possible. Not only are these animal manures highly nutritious, but the ammonia fumes arising from them do much to keep the foliage clean and healthy. Although well-established pot Roses need a considerable amount of nutriment, great care must be taken not to overdose them or they will turn sickly and may even succumb. When the plants seem to be thriving on the amount of food given do not be tempted to increase the strength, but leave well alone.

While the young foliage is developing it is important that sudden changes in temperature are avoided, such being productive of mildew and other ills. Open the ventilators just a little for an hour or two each day to keep the atmosphere sweet and buoyant. On really warm, sunny days air may be given more freely early in the morning, but it should be shut off again early in the afternoon. Mildew is almost sure to appear sooner or later unless some preventive is used. It is wiser to forestall the evil and commence syringing with a reliable fungicide as soon as the foliage begins to develop. Patent sprays must be used on young foliage with extreme caution as to the strength of the fluid, or irreparable damage will be done. An effectual wash for mildew is made with Cyllin soft soap dissolved in soft water, adding a little flowers of sulphur. It must be constantly stirred when using and applied with a spraying syringe. A very fine sediment will then be left on the foliage. Another good wash is made by dissolving 1 oz. of potassium sulphide, or liver of sulphur, in three gallons of soft water. Bordeaux mixture is a little more trouble to make, but is certainly the finest fungicide it is possible to use. An ounce of copper sulphate is dissolved in a little boiling water and left to cool; next

dissolve some lime in two gallons of water, and then slowly pour in the cold sulphate solution, stirring all the time. Bordeaux mixture must be used the same day as it is made. Whatever solution is used it should be applied very thoroughly, beneath as well as above the foliage. Incidentally, good and constant spraying will do much to keep in check that most harmful of hot-house pests—red-spider—for these insects cannot stand moisture. Green-fly is most easily and effectively destroyed by vaporising the house.

ROCK, ALPINE, BOG, FERN, AND WATER GARDENS.

SAXIFRAGA BOYDI ALBA.

NEXT to *S. Burseriana* Gloria and *S. B. major*, this beautiful species, which blooms later, is the finest of the early white-flowered Saxifragas. How well this plant may be grown and flowered in February without any protection is shown by the illustration on this page. The culture recommended for *S. B. Gloria* at page 99 also suits this plant admirably. The plant

the "A.M." from the Royal Horticultural Society, a year or so previously, ninety odd trusses of flowers. The high-mounded character of the example necessitated frequent mulching, and finely-screened sand was carefully strewn over it and worked and washed into the cushion. The suddenness of its death suggested a deadly fungoid attack or a dose of some virulent poison. All the same I inwardly vowed I would never again allow a plant to gain such a size without division. So far I have not had the opportunity. That, of course, is tantamount to a belief that to some extent at least a smaller, younger plant would have escaped. Unfortunately, continued experience points to the unpleasant fact that young and vigorous yearlings are by no means immune—also that frame-grown plants "go off" as badly, often worse than, others grown more fully exposed. Nor is it confined to a few plants. Indeed, a large grower told me a year or so ago of a 200 batch of one variety going to the rubbish heap at once. I immediately inquired, "Why not to the fire-heap instead?" Equally unpleasant, too, is the

centre I attribute to dryness and the rosettes getting out of touch with the soil. Division and the replanting of the rosettes of leaves right up to their bases are an easy remedy for these quick-growing sorts, all of which love moisture, or at least uniformly cool soil conditions. When a gap occurs in a choice cushion sort I have more than once cut away the decayed parts and thrust in a piece of sandstone or limestone, first filling the interior with good soil. In a surprisingly short time the new growth can be seen nestling closely to the sympathetic rock, an object-lesson of high teaching value when we remember that the greater proportion of these Cushion Rockfoils are rock-loving, and inhabit such places in Nature. Given this or its nearest possible equivalent—two-thirds finely-broken sandstone is good—and avoiding rich soils, the cultivator places at the disposal of his plants a dietary of a most congenial kind.

E. H. JENKINS.

ROYAL HORTICULTURAL SOCIETY.

APRIL 11TH, 1916.

THE fortnightly meeting held on this date was attractive and interesting. May-flowering Tulips in bowls of fibre were very fine. Alpine plant groups were numerous and good. Several collections of the choicest Daffodil novelties were on view. Of Roses, only one collection was shown, Carnations and Orchids being fairly represented. Few novelties received awards. The following are the more important exhibits:—

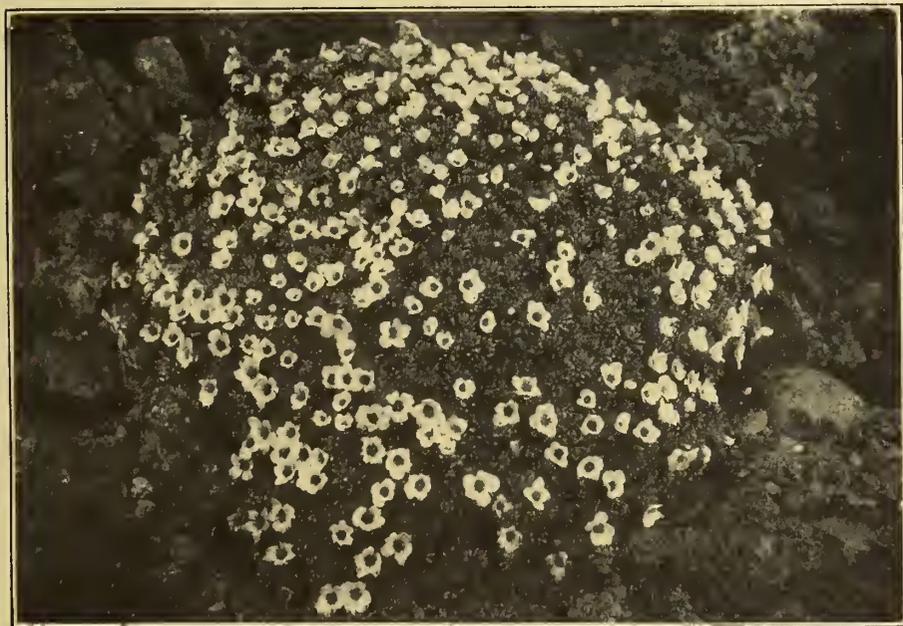

ALPINE AND HARDY PLANTS.

Messrs. Waterer, Sons, and Crisp, Bagshot and Twyford, showed many good things in conjunction with rockwork, none so brilliant, however, as a great patch of *Saxifraga oppositifolia* W. G. Clark, before which all others of its set pale. Later than the rest, too, it stands alone. Another distinctive member of the *Saxifraga* family was labelled *Elizabethæ* No. 5, its mass of orange-yellow flowers distinct from all. A dozen other things might have been selected; those named, however, are indispensable to every good collection.

Mr. G. Reuthe, Keston, Kent, had a collection particularly rich in Saxifragas, the brilliant-red flowered *S. retusa*, a new yellow not unlike *S. Paulinæ* in flower, which was also shown, named *S. Bileki*, being noted for the first time. The white Italian *S. Boryi*, too, and the golden-flowered *S. pungens* were others of note. Two brilliant things of widely diverse character, *Tulipa linifolia* (intense scarlet, dark base) and the lovely blue *Chillean Tecophylæa cyanoerens*, at once caught the eye. *Rhododendron fastigiatum* (a miniature with lavender-blue flowers) was among the choicest things.

Messrs. Piper, Bayswater and Barnes, contributed an extensive group wherein a wealth of Primulas was noted. The more important of these were hybrids of *P. viscosa* or nearly allied species, as *P. v. hybrida* (red), *P. v. Mrs. J. H. Wilson* (bluish, with white centre), *P. The General*, and *P. The Admiral* (reddish-crimson and dark crimson respectively). All are remarkably free-flowering. *P. Willmottæ* is a dainty novelty of recent introduction with lilac flowers.

Messrs. T. S. Ware, Limited, Feltham, showed excellent groups of *Trillium Snow Queen* and *T. erectum*, though without doubt the superbly-flowered pan of *Epigæa repens* was the gem of the whole. *Silene pusilla* (white) is a plant of great charm, if less showy than many Primulas on view or the lovely white-petalled, blue-backed

A single plant of Saxifraga Boydi alba at Lilford Hall, Oundle, Northants.

illustrated is growing in slightly more shade than is *S. B. Gloria* referred to above.

F. W. G.

Lilford Hall Gardens, Oundle.

DISEASE IN SAXIFRAGA BURSERIANA.

"AN AMATEUR OF HARDY FLOWERS" (page 159) suggests that probably I "may have something to say about this disease (if disease it be), which causes the plants to grow bare in the centre and gradually die off unless broken up and the best bits replanted." I very much fear, however, that I can throw but little light on the subject, though an examination of some of the surrounding circumstances might prove helpful to cultivators generally. Unfortunately it is not confined to the above-named species and its varieties, but affects the majority of the Cushion Rockfoils—thus dealing a rather severe blow at some of the choicest and best of these plants. I lost my unique specimen of *S. aretioides primulina* some fifteen years ago quite suddenly, after growing it for at least a like period, filling a 6-inch pot, and carrying at the time it received

fact that the wilding is not immune, and those who have handled large importations will recall the half-dead look of not a few rosettes in many tufts. I have twice or thrice spoken to Mr. Massee on the subject in the past, but that gentleman invariably declared he could find no trace of fungus on the stricken plants. Where then do we stand? Were the wilding but immune, and with no trace of disease in the younger-cultivated examples, we might accept the failure as a species of resentment to lowland climatic conditions or cultural error, or both. In existing circumstances we cannot. One cultivator of my acquaintance puts it down to overhead wet. Yet my fine specimen *primulina*, already referred to, bore sixteen years of it without any protection whatever. Then, too, if only old plants failed, the way would be more clear. It is not so, however, when the yearling or two-year-old from the cutting goes the same way. The silvery or encrusted set appears practically immune, though some of the *Cotyledon* varieties, and more rarely *longifolia*, suffer from a leaf-rust which is quite distinct from the disease under review.

The burning of the mossy kinds in the

Anemone blanda scythica, a plant for all.

In a small group from

Mr. Clarence Elliott, Stevenage, a batch of *Anemone vernalis* claimed attention. We do not remember to have seen so much of it so well shown before. A score of well-flowered *Primulas* Mrs. J. H. Wilson, of the *viscosa* set, blue with white centre, made a big show.

Messrs. Tucker and Sons, Oxford, brought rare and choice things well grown. Of these we selected the all-too-rarely-seen *Saxifraga Vandelli* (a valuable late, white-flowered species). Then the brilliant blue of *Gentiana verna angulosa* caught the eye. *Douglasia laevigata* (rosy), *Saxifraga Irvingi*, the beautiful *Androsace helvetica*, and *A. pyrenaica* were also well shown. From

The Society's Gardens, Wisley, was sent a variety of alpine in pans, the pride of the collection a unique specimen of *Saxifraga Griesbachi* bearing a score of its inflorescences. Smaller examples displayed much promise. Another rare species was the Himalayan *S. lilacina*. A big pot of *S. Burseriana* was full of bloom. *Androsace Lageri* and *A. L. alba* were also noted with *Primulas* and other plants.

Mr. James Douglas, Great Bookham, showed choice *Auriculas*, as *Klondike* (golden bronze) and Mrs. Gardner (pale lilac). Admiration (one of the best of the blue shades) and *White Czar* were others of note. There were some notable seedlings, a white-edged florist variety among them, which the raiser regarded as perfection.

CARNATIONS.

Messrs. Wm. Cuthbush and Sons, Highgate, N., staged an admirable lot of flowers, notably their new perpetual-flowering scarlet *Malmaison Sabina*, which was very fine. It is the most handsome and most refined-looking of its class we have seen. Mrs. L. D. Fullerton is a remarkably good lavender and red fancy. *Lady Ingestre* is one of the most charming of the pinks. Among greenhouse plants the firm showed the fragrant *Boronia megastigma* in plenty.

Messrs. Stuart Low and Co., Enfield, included great stands of *Gorgeous*, *Pink Sensation*, Mrs. C. F. Raphael, and *Baroness de Brien* in a handsome exhibit.

Messrs. Allwood Bros., Haywards Heath, had the new perpetual-flowering *Malmaisons Dragon* and *Terrific*, the bigger vases of *Fairmount* (fancy), *Mary Allwood*, *Champion*, and *Wivelsfield White* among others being shown to perfection.

TULIPS.

A double-width table of Darwin Tulips, grown in bowls of fibre, staged by Messrs. R. H. Bath, Limited, Wisbech, attracted everybody. It was one of the finest exhibits so cultivated yet seen, and was much admired. From the representative character of the exhibit, it was clear that all varieties were alike responsive to the treatment, hence we refrain from a list of names. In addition to the Darwins, Mrs. Moon and *Bouton d'Or* (yellows of the May-flowering set) were also remarked. Messrs. R. and G. Cuthbert, Southgate, N., showed an extensive collection of bedding Tulips in pots.

SHRUBS.

There was but one exhibit of these, that from Messrs. J. Cheal and Sons, Crawley, who arranged a highly meritorious group consisting of *Prunuses*, *Cerasus*, *Viburnums*, *Cytisus*, and others, in conjunction with a groundwork of Japanese *Acers*. The centre was a wealth of the pretty white-flowered *Spiraea arguta multiflora*,

over which appeared *Prunus serrulata pendula Chealei*, and *P. p. Hisakusa*, followed by a galaxy of *Prunus pseudo-Cerasus Sieboldi* fl.-pl. *Rhododendron Pink Pearl*, *Viburnum plicatum*, *V. tomentosum Mariesi*, and the lovely white *V. Carlesi* were all in good form. The margin was of *Senecio Grayi* and pans of alpine.

GREENHOUSE FLOWERS AND PLANTS.

Messrs. Sutton and Sons, Reading, contributed a collection of *Star*, *Cactus*, and florists' *Cinerarias*, a full table length being occupied by the plants. Of the former, *Feltham Beauty* (blue) and *Feltham Beauty* (white) are singularly beautiful. The former is of an excellent shade of colour. In the last-named set the pink shades were very fine, a rose-pink being very effective. Messrs. Sutton also displayed a choice lot of Darwin Tulips in the cut state, many fine sorts, as *Clara Butt*, *Queen of Roses*, and *King Harold* (glowing crimson) being some of the best.

Messrs. H. B. May and Sons, Edmon-ton, arranged groups of *Hippeastrums* (*Amaryllis*) with *Clematis montana grandiflora* and *C. indivisa lobata*. Among Ferns, of which there were many, the rare *Adiantum sulphureum* was one of the most important. Well named, it is an elegant and beautiful kind from the mountains of Peru, lost to cultivation for many years. It is reputedly as hardy as the British Maidenhair, and, therefore, all the more valuable.

ROSES.

The group of these from Messrs. B. R. Cant and Sons, Colchester, was very finely displayed, the blooms in boxes equal to those of a summer exhibition. *Lady Roberts* was particularly good, also *Pharisæer* and *Hugh Dickson*. The new Hybrid Tea *Hon. Mrs. R. C. Grosvenor* (gold and pale flesh-pink) was very beautiful. *Captain Cant* and *Juliet* were others of note in an excellent fresh-looking lot.

NARCISSI.

Mr. Alex. M. Wilson, Shovell, Bridgewater, showed many choice novelties. Two of his best, *Palermo (Barri)* and *Ozan* (bicolor *incomparabilis*) secured Awards of Merit. In addition, we selected *Cresus*, *Mistral* (a giant even amid giant *Leedsii* forms), *Robespierre* (with brilliant crown), *Duessa* (white), *Volvic* (a fine *Englehearti*), and *Cranbourne* (rich golden-yellow *Ajax*).

Messrs. Barr and Sons, Covent Garden, W.C., also had a formidable lot of flowers, from among which we selected *Ruby (Barri)* (fine cup), *The Czar* (giant *Leedsii*), *Basilia* (of the same set), *Anzac*, *The King*, *Lord French*, and *Golden Sovereign* (all yellow *Ajax* sorts of outstanding merit and distinction). *Ixion* is a notable *incomparabilis* and a great *Daffodil* withal.

Messrs. R. H. Bath, Limited, Wisbech, received an Award of Merit for *Double Sir Watkin*, said to be a sport from the original. *White Knight* (white *Ajax*), *Flame*, *Golden Sunrise* (very early), *Decorator* (big golden *Ajax*, with remarkable crown), and *Eastern Maid* (*incomparabilis*) were others of merit. In a collection from

Messrs. H. Chapman, Limited, Rye, *Statuesque* (bicolor *incomparabilis*), *Shrove* (*Englehearti*), *Downeast* (a good name for an exceptionally drooping bicolor *Ajax*), and Mrs. *Welesley* (*Leedsii*) were some of the best-named sorts. High-class seedlings were, however, prominent.

ORCHIDS.

Two good things from Messrs. Charlesworth, Haywards Heath, were *Odonto-*

glossum Jasper and *Dendrobium Jamesianum*.

Messrs. Cypher had *Vanda coerulescens*, *Epiphronitis Veitchi*, and *Cattleya Robert de Wavrin*.

Messrs. Sander and Sons, St. Albans, had an excellent specimen of *Odontoglossum Polyphemus* (gold and crimson), *Lycaste Skinneri* Mrs. G. Hamilton-Smith, and *Cologne Lawrenceana* were also noted.

Messrs. J. and A. MacBean, Cooks-bridge, showed many good *Odontiodas* and *Odontoglossums*. *Cattleya Schroderae* was very fine.

Messrs. Felton and Sons, Hanover Square, W., employed *Cymbidiums*, *Odontiodas*, and *Odontoglossums* lavishly in the cut state in bold vases.

A complete list of the plants certificated and the medals awarded will be found in our advertisement pages.

THE WEEK'S WORK.

OPEN-AIR GARDENING.

IN BLOOM APRIL 6TH.—*Cydonias* (various colours), *Chinese Quince*, *Rubus spectabilis*, *Magnolia stellata*, *Berberis* (in variety), *Azara microphylla*, *Ericas* (in variety), *Daphnes* (various), *Alnus cordifolia*, *Spice-bush* (*Laurus Benzoin*), *Andromedas* (in variety), *Prunus triloba*, *Myrobalan Plum* (*P. cerasifera*), *Periwinkles*, single and double *Camellias*, *Skimmia fragrans*, *Phillyrea decora*, *Rhododendron Jacksoni*, *R. venustum*, *R. ciliatum*, *Forsythias*, *Ribes sanguineum*, *Caltha palustris*, *Caltha polypetalata*, *Arenaria balearica*, *Anchusa myosotidiflora*, *Viola graecis*, *Chionodoxas* (in variety), *Wall-flowers*, *Anemones* (in great variety), *Fritillaria Melcagris*, *Synthlipsis reniformis*, *Dog-tooth Violets* (in variety), single and double *Arabis*, *Aubrietias* (in variety), *Primroses*, *Narcissus* (numerous kinds), *Crocuses*, *Snowdrops*, *Grape Hyacinths* (in variety), the *Algerian Iris*, *Primula rosea*, *P. viscosa* Mrs. Wilson, *P. Julia*, *P. casimeriana*, *Collinsia grandiflora*, *Rosemary*, *Polyanthuses*, *Lithospermums*, *Saxifrages*, *Gentiana acaulis ex-cisa*, *Lenten Roses*, *Hutchinsia alpina*, *Anemone Hepatica* (in variety), *A. angulosa* (in variety), *Scillas* (in variety), *Puschkinia scilloides*, *Narcissus odoros* (*Campernelle*), *Barrenwort* (*Epimedium sulphureum*), *Forget-me-nots*, *Violet Cress*, *Hyacinthus azureus*, blue and white *Omphalodes verna*, *Summer Snowflake*, *Veronica filiformis*, *Candytuft*, the *Bardfield Oalip* (*Primula elatior*).

WORK OF THE WEEK.—Pruning of dwarf *Roses* continues. The beds have been forked over, and such plants as are available and likely to last through the summer are being used to carpet them. *Carnation* beds have been cleaned and forked over to encourage growth. The past winter has been most unfavourable to *Carnations*. A long border raised above the ground level has been prepared and planted with *Aubrietia Peter Barr*. To carry this through it was necessary to shift some large plants of *Muhlenbeckia complexa*, which although very attractive when falling over this low wall, were too rampant, and threatened to take possession of the path. These have now been given a more open place where their long, graceful trails may ramble freely. A support of some rough poles or similar material may be given them later, as they are rarely seen to better advantage than when furnishing tall poles. The winter protection has been removed from the *Wand-flower* (*Sparaxis pulcherrima*) and the plants relieved of old, disfigured foliage. Seedlings of this most graceful plant from seed sown in February are growing freely. A few plants of *Raoulia australis*, *Sedum Sempervivum*, *Rosy Arabis*, and *Saxifrages* have been planted out on a sunny border, and a group of *Lysimachia ciliata* has been planted by the water-side. *Cornus Nuttalli* has been given a place in the Heath garden, and a further batch of the little *Sand Myrtle* (*Leiophyllum buxifolium*) has been added to an existing group near by. *Tree Lupins*, which were severely damaged by the recent sharp frosts, have been pruned hard back to encourage growth from the base. A few *Roses* have been planted and edgings of dwarf trailing plants, such as the dwarf *Gypsophilas*, have had to be cut hard back. The earliest-sown *Sweet Peas* are now thoroughly exposed, and will be planted out on specially prepared ground immediately they have been hardened off. Seedlings of perennials and hardy annuals have been removed to cold frames, where they are kept on the dry side as the nights are very cold, and damping is liable to occur if the seed-pans are kept too wet. A quantity of the *Balearic Box* and the *Handsworth Box*, having come to hand, a place has been provided, where they will form a shelter and clothe a border beneath *Pine-trees*, where choicer shrubs are not happy. E. M. Sussex.

SOUTHERN COUNTIES.

Sweet Peas.—Should the milder conditions now prevailing continue, the seedlings raised in pots in January will be set out in rows on ground which was prepared for them some time ago. Moulding and staking will follow after the planting, and to shelter the plants from cold, cutting winds the spray taken from the upper part of the boughs when they were being prepared for the purpose will be worked in between the stakes at the base on either side of the rows. More seed will now be sown outdoors in rows 12 feet apart.

Antirrhinums.—These are now ready for pricking off. A couple of pits will accordingly be prepared for the purpose, some fresh loam and leaf-mould being added to the soil already present in them. This when forked over will afford a good rooting medium for the plants, and from which they can be lifted with good balls. A distance of from 4 inches to 5 inches will be allowed between the plants either way, this affording ample space for their development, as they are lifted and planted out so soon as they grow out and touch one another. Until the plants make new roots and recover from the pricking out they will be shaded and the pit kept closed. A gentle dewing overhead serves to keep the plants from flagging and assists in their becoming the more quickly established.

Alonsoa.—The compact-growing form of *A. Warsceizii* is most useful for planting in beds and borders for summer effect. It is a slender-growing half-hardy annual, and is best raised in slight warmth in spring. The plants are now ready for pricking off, and boxes will be employed for the purpose. In these the plants will be set out 3 inches apart each way.

Phlox Drummondii.—These will be dealt with in the same way as the preceding, and subjected to slight warmth until they are established. After this a frame will provide suitable quarters.

Isleland Poppies.—These do best when treated in the same way or until the plants are large enough for setting out in lines and groups outdoors. The flowers are extremely valuable for table decoration when used in conjunction with the finer forms of ornamental Grasses. In addition to the usual white, yellow, and orange forms, intermediate shades, which are very beautiful, are now to be had.

Ten-week Stocks.—These will now be sown and pricked off as soon as large enough to handle. If allowed to remain in the seed-boxes until they get leggy and starved before this is done the results are very disappointing.

Asters.—The present is quite early enough to sow the single varieties if they are not required for creating a display before September next. Raised in gentle heat and pricked out as soon as large enough, they make good plants for setting out finally in the middle or end of May. The variety named Southcoate Beauty, which can now be had in several distinct colours, is the finest of the single kinds.

Canterbury Bells.—To obtain good plants for planting in autumn it is necessary to raise them in good time. If seed is sown in the middle of the present month and allowed to germinate in a frame the plants are more robust and can be pricked out on a border when ready without risk. All are very beautiful when in bloom, but the single varieties are the more adapted for the wild garden. The Cup and Saucer varieties in various shades make excellent pot plants for greenhouse decoration. They should be potted in time to get thoroughly established by the end of autumn.

Protected wall plants.—Of these, Myrtles, Ceanothuses, Pomegranates, Magnolias, and the Scented Verbena will be uncovered, as frost likely to do them harm need not be apprehended after this date. The last-named is spurred in close to the old wood, unless there are any vacant spaces present, when the most conveniently situated of last season's growths are left for furnishing them with. Severe pruning is necessary if the plants are to be kept close to the wall, as they grow rampantly. Magnolias require no pruning, the principal thing in their case being to see that the main branches are properly secured to the wall by making good all faulty ties. Myrtles also require but little attention, but Ceanothuses need a slight shortening of the wood, care being taken that the branches generally are securely fastened to the wall. The Mexican Orange-blossom (*Choisya ternata*), although sufficiently hardy not to require protecting like the foregoing, needs to be overhauled every season, as weight of branchlets and foliage is such that the ties, unless frequently renewed, soon give way, with the result that the plants come away from the face of the wall and become badly damaged.

Sowing vegetable seeds.—A general sowing of these, comprising Turnips (in three varieties to form a succession), Globe Beet, Spinach, Radishes, Lettuces of both Cos and Cabbage kinds, maincrop Peas, and Broad Beans will now take place. Small seeds, such as Cauliflowers, autumn, mid-winter, and spring Broccoli, early and maincrop Savoys, Cabbage for summer and autumn cutting, Kales in variety, and Sprouting Broccoli will also be sown. For convenience in netting—to render the foregoing safe from bird attacks—all will be sown together on a border in drills drawn 9 inches apart.

Autumn-sown Cauliflowers.—As these have not, owing to the nature of the season, yet been planted out they have, as a result, become rather larger than is desirable. They will now be planted out without further delay on ground in good heart, watered and sheltered for a time when necessary from cold winds and on frosty nights. A second batch of plants now being hardened off will be ready for setting out in a fortnight's time.

Brussels Sprouts.—The earliest plants raised under glass are being exposed to the outer air daily with a view to getting them properly hardened so that planting out may be effected before the end of the month. They will be planted in rows 3 feet apart with a distance of 2½ feet between plant and plant.

A. W.

MIDLAND COUNTIES.

Strawberry beds.—The beds should be hoed through during dry weather so that the land may be thoroughly cleaned before it is time to put on a mulch. Perennial weeds, as Docks, Dandelions, etc., should be removed by extracting the roots before they have time to establish themselves. Care must be taken when doing this not to injure the roots of the Strawberries. When Strawberry plants have become established all the cultivating that is required may be done with the hoe. To obtain good runners for early planting a number of strong, healthy plants should be reserved for this purpose and the flowers pinched off as soon as they can be seen, which will cause the whole of the plant's strength to be diverted to the production of runners.

Peaches and Nectarines have made little progress in the Midlands during recent cold weather, but attention to the means of protection, previously advised, has preserved the flowers from injury, and the fruits promise to set well. As soon as the petals fall, disbudding is commenced and completed in several operations at intervals of a week or ten days, according to the growth of the trees. Disbudding requires much judgment, for if too many buds be removed at one time a check will result and many of the fruits will turn yellow and fall off. The shoots at the back and front of the branches should be first removed, any young fruits found at the base of the shoot being left if it be thought desirable to retain them. It is a better plan to nip off the point of the shoot in this case, leaving the base of the shoot with the young fruit on it. The points of the shoots should for the present not be pinched. It may be necessary with some of them later on to avoid crowding, but the third disbudding is the best time to do this. If fruits have set thickly, the worst placed should first be removed, and the others left on the branches, and shoots at 3 inches apart, always removing those that are small and weak.

Ventilating.—By the time these notes appear the weather should have become more genial, so that freer ventilation will be necessary. Most plants derive much benefit from a good circulation of air during the earlier part of the day, followed in the afternoon by a good syringing at the time the ventilators are closed and the temperature allowed to run up with sun heat. It is necessary to be cautious in ventilating Roses and other plants liable to mildew or in creating draughts in any way when the air is cold.

Euphorbia jacquiniæflora should be propagated as soon as cuttings are obtainable. When the new growths reach a length of about 3 inches they should be cut off close to the old wood and inserted in small pots filled with a mixture of peat and sand. Water well in and plunge in the propagating pit with plenty of bottom-heat. The lights should be kept close (except for a few minutes daily to expel excessive moisture) until they strike.

Poinsettias.—The present is a good time to start a batch of these for early cuttings. I prefer to begin now by putting the cut-back stools into an intermediate temperature rather than waiting till later and then forcing them on in more heat. At first these plants will require no water at the roots, what they receive from frequent syringings being quite sufficient to begin with.

Violets.—If really good flowers are required it is not wise to allow the plants to occupy the same place for a longer period than three years. At the completion of flowering is the best time to make new beds and borders. The position will be determined by the soil and locality. In light soils the single Violets thrive on a north border, but in a colder heavy soil a more sunny position is desirable. Before planting, the soil should be worked into a friable condition, and if very heavy should be lightened by the addition of sand, leaf-mould, decayed manure, etc. General work in this department now consists in sowing and planting out the various crops which have been wintered under glass, and giving constant attention to those already established in the open and growing in frames, pits, etc. Severe frosts may occur at any time during the next month, which would ruin many of the more tender subjects if left to chance, whereas a small amount of protection will make them safe. The ground should be cleared of all winter crops, such as Brussels Sprouts, Kales, Broccoli, Turnips, etc., as they can be spared, to prevent them starving the ground. Well manure and trench the various plots, and

allow the ground to rest as long as possible. The soil should be kept well hoed among all growing crops. The more often it is moved among such crops as Cabbage, Cauliflowers, Spinach, Turnips, and Lettuce, the more rapid will be the growth, and at the same time the ground will be freed from weeds.

Broad Beans.—When the plants have reached a height of about 4 inches the rows are moulded up to steady the plants. Another sowing will be made now of Green Windsor and Beck's Green Gem for furnishing pods in July and August.

Peas raised in pots under glass, after thorough hardening, have been planted out on a well prepared and sheltered piece of ground. The stakes were placed in position, a little soil drawn up to the plants, and small branches of Spruce stuck along the rows to give shelter against wind and frost. To ensure a constant and regular supply of Peas from the end of May till late September sowings will now be made every fortnight. The large Marrowfats are always most appreciated. These must be sown thinly—1 quart should sow about 120 feet. The best land available should be chosen for this important crop. Make the soil firm before sowing. The drills should be flat at the bottom, 6 inches wide, and 3 inches to 4 inches deep.

F. W. GALLOP.

SCOTLAND.

Beds of spring flowers.—In the course of the week all the beds of spring flowers have been looked over. Growth is now advancing steadily, although the season is by no means an early one in respect of many spring-blooming subjects. Tulips and Narcissus, being planted chiefly with a view to cutting, the bulbs are put out rather thickly, and it is in some cases difficult to stir up the soil without doing damage. Wallflower is later than usual, and, on the whole, has not done so well. The reason may be found in the exceptional rainfall and the prevalence of east winds, which knocked the plants about to a considerable extent. Plants which had become loosened were made firm, and with the much milder weather now prevailing progress will be more rapid. Chionodoxas in variety are bright and effective, and Anemones (both *A. coronaria* and *A. stellata*) will not be much longer delayed, while *Myosotis* will shortly be in bloom.

Wall shrubs.—Some time was devoted to looking round flowering and other shrubs on walls. Forsythias are very effective just at this time, and need but little attention at present, with the exception of securing any sprays loosened by wind. *Pyrus* (*Cydonia japonica*), as usual, is flowering freely. On the same wall an old piece of *Wistaria* will soon be in bloom. *Kerria japonica* fl.-pl. is full of buds which will expand before long. This shrub, if the soil is at all rich, is apt to get a little out of hand, but as its blooms are always welcome it is not pruned too severely. The growths of *Ceanothus* (principally *C. Gloire de Versailles*) have been regulated. A little pruning in the case of the Winter Sweet (*Chimonanthus fragrans*) was done. If the shoots are spurred back to three or four eyes, plenty of young wood which will flower freely next season is produced. *Fuchsias* on a south wall are already breaking into leaf. The flowering season of *Jasminum nudiflorum* having ended, the usual pruning will be attended to shortly. This is never done too severely. *Escallonia macrantha* makes a useful wall shrub were it only for the beauty of its glossy green foliage. This can be confidently recommended to those whose gardens are near the sea, as is the case here. *Garrya elliptica*, highly satisfactory in its season, will also be lightly pruned in a short time.

In the woodland, as is customary at this time, a look round was given during the week to all young or recently-planted trees in order that any over-tight ligatures and faulty stakes might be seen to. Gorse is now a sheet of yellow, and while it tends to become too common and to increase too rapidly, yet its beauty in spring cannot be denied. Very many kinds of *Narcissi* naturalised in Grass begin to be effective, and *Crocuses* yet maintain an excellent display. The yellow varieties, however, are conspicuous by their absence. They seem to have a special attraction for voles or mice, and the corms have evidently been destroyed. Primroses are numerous. *Laburnums* and *Thorns* of different kinds promise a good display, while *Wood Hyacinths* in all the different colours are rapidly advancing.

Shrubberies.—Here, too, young or recently-planted stuff was looked over during the week. Despite the rather unfavourable winter, the majority of shrubs appear to be in robust health. Lavish displays of bloom will shortly be afforded by the various *Barberries*, *B. Darwini*, as usual, being literally covered with flowering sprays, as is *B. stenophylla*. Some stray pieces of *Mahonia* are planted chiefly for their fragrant blossoms, but they do not, in the situation where they are grown, get out of hand—a state of affairs which sometimes happens when *Mahonia* is injudiciously planted. *Choisya ternata* is well budded, and, suited by exposure and soil, is developing into fine pieces. *Ribes sanguineum* is very free, and *Azaleas* are moving rapidly. *Rhododendrons* will be very fine. The deep, rich, peaty soil suits them, and the individual plants are very large. *Deutzias*, both *D.*

CORRESPONDENCE.

Questions.—*Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly written on one side of the paper only, and addressed to the EDITOR of GARDENING, 63, Lincoln's Inn Fields, London, W.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent each should be on a separate piece of paper, the name and address being added to each. As GARDENING has to be sent to press some days in advance of date, queries cannot always be replied to in the issue immediately following their receipt. We do not reply to queries by post.*

Naming plants.—*All who wish their plants to be rightly named should send fair examples of each—the stem, leaf, flower, or fruit. (Snippets of leaves and points of shoots are useless.) Not more than four plants should be sent in any one week by the same correspondent. Where more than one kind is sent they should be numbered. Of confers the fruit should always be sent.*

Naming fruit.—*Several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. We can undertake to name only four varieties at a time.*

PLANTS AND FLOWERS.

Treatment of Camellias whilst flowering (C. B.).—Keep the structure as cool as possible from now onwards, shading against hot sun. The more gradually the blooms expand, the larger and finer they will be. Give plenty of air in the daytime, and take care that the plants do not at any time experience the want of moisture at the roots. Be careful to never wet the blooms in syringing.

Stunted Abutilons (Abutilon).—The best thing to do with the Abutilons that have become pot-bound, stunted, and starved, is to cut them somewhat hard back, and when fresh growth commences, turn the plants out of the pots, disengage and shorten the ball of roots, and shift them into larger pots than those they came out of, using some fresh loam mixed with well-rotted manure and a sprinkling of sand. When the plants have made fresh roots and growth they will bloom plentifully. Syringe freely in the summer to keep down red-spider.

Treatment of Ericas (Heath).—The proper way of treating such soft-wooded Ericas as bloom in winter is to cut them down to just below the blooms as soon as the latter fade. They are watered carefully until they begin to make growth, and are then shifted into pots one size larger. The best peat must be used, with plenty of white sand and good drainage, ramming in the compost well round the ball. The plants are kept in a cool-house until the middle of July, and are then stood in the open air till the middle of September. Attention to watering is all important.

Propagating Plumbago capensis (Plumbago).—This Plumbago strikes readily from cuttings made of the young shoots taken off in spring, when 4 inches or 5 inches long; these will be forthcoming from plants that have been cut back early, and if they have a heel of old wood attached all the better. Put them singly into little pots filled with loam and sand, the surface all sand; keep under a bell-glass, or in a propagating frame, moist, and shaded in a moderate heat (bottom heat is not essential). They will soon root, and after which inure them to the full air of the house.

Old Zonal Pelargoniums and Heliotropes (A.).—In the case of old leggy specimens of either of these plants the best plan will be to cut them down to within a few inches of the base of the old branches at once if there is a comfortably warm house at command in which to place them. As soon as fresh growth of about an inch in length has been made the plants should be repotted, shaking a good portion of the old soil away from the roots, and putting them into as small sized pots as possible. Use a loamy compost for the Pelargoniums, and a rather lighter one for the Heliotropes. The after-treatment for Pelargoniums will mainly consist in moderate waterings, and abundance of light and air. The Heliotropes require more moisture and a closer atmosphere.

Culture of Kalosanthos (L. K.).—Pot off the cuttings at once into small pots, in a compost of two-thirds turfy loam and one-third leaf-mould, keeping them rather close for a time until the roots are working freely. Stop the points of the shoots to induce a bushy

habit, and shift, when necessary, into 4-inch pots, placing the plants in a sunny, well-ventilated position in the greenhouse. The Kalosanthos, being of a succulent nature, requires a considerable amount of sun heat to mature the wood, without which the flower-heads do not form. During the early part of September the plants will be benefited by fuller exposure to sun and air, wintering them in a cool-house, and ventilating freely during the early spring months.

Treatment of the Scarborough Lily (Val-lota purpurea) (Inquirer).—This blooms best when root-bound. In a general way, repotting is only advisable when the plants have been several years in the same pots. Small bulbs should be annually repotted until they come to blooming size, and then it is better to let them alone for several seasons. If allowed to remain undisturbed the bulbs will raise themselves and the soil above the level of the pot, but this does not matter if they only get enough water when growing. When old specimens are broken up the young bulbs are best put into 2½-inch pots, half-a-dozen together, to remain thus till the following spring. Good loam, with some leaf-mould, is what they like. Pot firmly, bury the bulbs to half their depth, and drain the pots well.

Culture of the African Hemp (Sparmannia africana) (J. A.).—Established plants of this should be cut in somewhat at this time, as unless this is done they are apt to get leggy by the autumn. Keep them for a time on the dry side, merely watering until fresh shoots some 2 inches long are formed. Then water more freely, and if the pot is full of roots shift into the next sized pot, in a compost of equal parts turfy-loam and well decomposed leaf-mould, adding thereto some coarse silver sand. Keep rather close for a time, syringing on fine days and ventilating when the weather is mild. As soon as the plant has become well established apply a top-dressing of manure which is better than shifting again, as this plant, like many others, blooms most freely when the soil becomes thoroughly packed with fibres by the beginning of the winter. Give abundance of air during the summer months, and about the middle of August turn the plants out into the open air in a sheltered situation, there to remain until the middle of September, when they should be placed in their winter quarters. The Sparmannia blooms in winter if placed in a light structure where the temperature ranges from 50 degs. to 60 degs. When wintered in a cool house it blooms later. Cuttings taken off in the summer strike freely in a shady close frame, inserting them in sandy peat.

TREES AND SHRUBS.

Insects on Myrtle leaves (A. B. P.).—The Myrtle leaves are infested with brown-scale. The plant should be thoroughly and frequently washed with soapy water and Tobacco juice, applied by a syringe. If the scale is dislodged by a piece of pointed stick it will the more readily be washed off. The plant should be laid on its side when washing it, to prevent the mixture reaching the roots.

VEGETABLES.

Bottling Green Peas (L. C. D.).—Green Peas for bottling should be quite young, and also of one size. Put them into wide-mouthed bottles, with a pinch of salt on the top. Stand the bottles up to their necks in a large pot of water, which stand over a fire and boil slowly. So soon as the Peas seem to be soft, take the bottles out, cork them up, seal them over, and keep them in a cool, dry place. Bottling of Green Peas is work that is best done by someone who has intimate knowledge of the business, as a slight mistake may lead to failure.

MISCELLANEOUS.

Leaf-mould (R. W.).—There is no special process of any kind needed to make leaf-mould. All that is required is to collect the leaves as soon as they can be obtained after being shed from the trees in the autumn. The heap must be turned over until the violent heat caused by fermentation has passed away. The heat becomes so violent sometimes as to cause the leaves in the centre to become quite scorched, as it were; when this happens, turning the heap over will bring these over-heated leaves outside, and the outer portion will be turned inside. They require to be turned about three times before the heat is sufficiently subdued.

NAMES OF PLANTS AND FRUITS.

Names of plants.—*H. J. W.*—*Prunus japonica* flore-pleno.—*Miss A. Donovan.*—*Berberis huxifolia* (syn. *B. dulcis*).—*A. B.*—1. *Sedum Sieboldi* variegatum; 2. *Caltha palustris*; 3. *Anemone nemorosa*; 4. *Pulmonaria officinalis.*—*Rose.*—1. *Diplacis glutinosus*; 2. *Choisya ternata*; 3. *Aubrietia Cambelli*; 4. *Narcisse Telamonius plenus.*—*F. J. R.*—1. *Clivia miniata*; 2. *Habrothamnus elegans*; 3. *Francoa ramosa.*—*M. C. B.*—1. *Scilla hifolia*; 2. *Ornithogalum nutans*; 3. *Narcissus Telamonius plenus*; 4. *N. Barri conspicuus.*—*T. D.*—1. *Ribes sanguineum*; 2. *Doronicum austriacum*; 3. *Cydonia japonica*; 4. *Kerria japonica* fl.-pl.—*L. F.*—1. *Anemone pennina*; 2. *Anomatheca cruenta*; 3. *Berberis Darwini.*—*S. B.*—*Chionodoxa Lucilii grandiflora* (syn. *C. gigantea*).

gracilis and *D. crenata* fl.-pl., are freely planted, and, although they occasionally get nipped by a late frost, yet, as a rule, these delicate shrubs flower well. Fuchsias in variety, in all possible exposures, are looking well. *Andromedas*, *Kalmias*, and *Viburnums* will assist in the display, and the shrubby *Spiraeas* of many kinds are effective over a long season. Among fine-foliaged shrubs, *Aucubas*, *Box*, *Hollies* of many kinds, *Veronicas*, and *Bays* give relief and variety.
